The last Matriculation Examination for students in the Faculty of Medicine is held on the 16th of November.

Fee for Matriculation, 10s.

Students in one of the Queen's Colleges, or in any University, are permitted to take corresponding rank in one of the Queen's Colleges, and to compete for scholarships of the corresponding year.

*Medical Scholarships.*—Of the eight Junior Scholarships appropriated to the Faculty of Medicine, two will be awarded in each of the four years.

Candidates must be matriculated before they can compete.

Students intending to compete for Scholarships of the Second Year must have attended in one of the Queen's Colleges, or in a University, two of the following, viz. :—Chemistry—Botany and Zoology—Anatomy and Physiology—Materia Medica and Pharmacy—Practical Chemistry—Practical Anatomy.

For Scholarships of the Third Year they must have attended four of the following, viz. :—Chemistry—Botany and Zoology—Anatomy and Physiology—Materia Medica and Pharmacy—Practical Chemistry—Practical Anatomy.

For Scholarships of the Fourth Year must have attended in their third year two of the following, viz. :—Medicine—Surgery—Midwifery and Diseases of Women and Children.

To acquire a year's standing, the student, whether matriculated or not, must attend two of the classes above mentioned.

*Examinations.*—Junior scholars are exempted from the payment of one moiety of the class fees.

*Exhibitions.*—The College is empowered to award Exhibitions, varying in value from £10 to £20, at the same Examinations as the Scholarships, and to be held upon the same terms.

Exhibitioners are required to pay the whole amount of the class fees.

All junior scholars and exhibitioners must attend lectures, and pass the sessional examinations.

*Prizes.*—Two prizes for English Prose Composition and two prizes for Geometry have been founded in the College, to be awarded annually at entrance :—First prize for English Prose Composition, £3 worth of books; second, do., £2 worth. First prize for Geometry, £3 worth; second, do., £2 worth.

*Fees.*—The College fees payable by matriculated students are 10s. for the first year and 5s. each subsequent year.

The fees payable for attendance on courses of lectures are £1 for each course of one term only, and £2 for each course of more than one term, when attended for the first time, and £1 for each re-attendance on the same.

This rule applies in all cases except the following :—

The fee for Anatomy and Physiology is £3 for the first time, and £2 for every subsequent attendance; and for Practical Anatomy or Practical Chemistry is £3 for each attendance.

The fees for honour courses are £2 for each course.

This rule does not apply to Practical Chemistry or Operative Surgery. In the former case the fee is £1 a month. Operative Surgery is £3.

A detail of the prizes and exhibitions in arts and medicine, the names of the professors, and other information, will be found in the *Advertisements* of this issue, and full details may be had on application to—

*Bel/aw.*—Rev. Richard Oulton, Registrar.

*Cork.*—Robt. John Kenny, Esq.  
*Galway.*—Thos. W. Moffett, LL.D.

### PRIVATE TEACHING IN DUBLIN.

IN the School of the Royal College of Surgeons the Senior Demonstrators are associated together for the purpose of private teaching, each gentleman giving instruction in special branches.

Mr. Croly	} in Surgery, Anatomy, Physiology, and Medicine.
Dr. W.T. Stoker	
Dr. L.H. Ormsby	
Dr. W.J. Smyly	

Dr. W. Handsel Griffiths, Librarian at the College of Surgeons, will meet his Classes for Professional Examinations on the 1st of October.

There is also a firm of teachers composed of Dr. Stoney (one of the Senior Demonstrators), Dr. Wheeler, and Dr. William Stoker.

Dr. Stoney	} instructs in Anatomy, Comparative Anatomy, Zoology, Physiology, and Pathology.
Dr. Wheeler	
Dr. Wm. Stoker	
	} instructs in Surgery, Medicine, and Anatomy.
	} instructs in Materia Medica, Botany, Chemistry, Physics, Jurisprudence, and Prescriptions.

In the Trinity School—

Dr. W. Smith receives pupils privately and in class in Materia Medica, Chemistry, and Botany.

Dr. Finny and Dr. E. W. Collins conjointly conduct a class at the School of Physic in Medicine, Forensic Medicine, Surgery, Anatomy, Physiology, and Midwifery. They also receive private pupils in these subjects.

Mr. J. Barton receives pupils in all the subjects of the various examinations.

In the Carmichael School—

Dr. Corley	} Anatomy, Physiology, Surgery, and Medicine.
Dr. Kelley	
Dr. Cameron	} Materia Medica, Chemistry, and Botany.

In Steevens' Hospital and School—

Mr. Swan.	} Chemistry, Botany, and Materia Medica.
Dr. Bookey.	
Dr. Bell	

Dr. Tweedy—Preliminary Examination.

In the Catholic University private teaching is conducted by Drs. Hayes, Coppinger, and Nixon.

In the Ledwich School—

Dr. Ledwich and
Dr. Mason, assisted by
Dr. Ward,
Dr. Corry,
Dr. Battersby.

### RELATIVE COST OF MEDICAL EDUCATION IN IRELAND.

(Exclusive of private teaching.)

UNIVERSITY OF DUBLIN M.B. and M.Ch.—1. Lectures, £52 15s.; 2. Hospitals, £33 12s.; 3. Degrees, £32—£118 7s.; expense of Degree in Arts, £83 4s. Total, £201 11s.

QUEEN'S UNIVERSITY M.D. and M.Ch. (all lectures being taken in the provincial colleges.)—£62 9s.; ditto (two years lectures and hospital taken in Dublin), say, £75.

ROYAL COLLEGE OF SURGEONS and KING and QUEEN'S COLLEGE OF PHYSICIANS L.R.C.S.I. and L.K.Q.C.P.I., £128 18s..

APOTHECARIES' HALL, L.A.H., £50.

## TECHNICAL EDUCATION IN IRELAND.

## THE ROYAL COLLEGE OF SCIENCE.

THE educational staff of this institution consists of nine professors, one demonstrator, and one laboratory assistant. It supplies, as far as practicable, a complete course of instruction in science, applicable to the industrial arts, especially those which may be classed broadly under the heads of mining, agriculture, engineering, and manufactures.

The course of instruction extends over three years, each year being divided into two terms. In the first two years the instruction is general. In the last year it is specialised under the heads of mining, agriculture, engineering, and manufactures.

There are four royal scholarships of £50 yearly each, with free education, tenable for two years; two will become vacant each year. They will be given to students who shall have been a year in the College.

There are also nine royal exhibitions attached to the College, of £50 each, tenable for three years.

The session commences on the first Monday in October, and lasts until 21st June following.

The fees payable are £2 for each separate course of lectures. (For further particulars see Advertisement, or apply to F. Sidney, Esq., LL.D., Royal College of Science, Dublin.)

## DUBLIN INTRODUCTORIES.

School of Physic—None.

Royal College of Surgeons—Dr. Emerson Reynolds—October 26th

Catholic University—Dr. Hayden.

Ledwich School—Dr. Kelly—November 2nd, 12 noon.

Carmichael School—None.

Dr. Steevens' Hospital School—None.

Meath Hospital—Dr. L. H. Ormsby.

City of Dublin Hospital—None.

St. Vincent's Hospital—Dr. Mapother.

Mercer's Hospital—None.

Mater Misericordiarum Hospital—Dr. John Hughes

Jervis Street Hospital—None.

Richmond Hospital—Dr. W. Thomson—November 5th.

Adelaide Hospital—None.

## MEDICAL EDUCATION IN SCOTLAND.

## THE UNIVERSITIES.

THE fees for degrees in all four of the Scottish Universities are uniform—viz.: M.B., £15 15s. (being £5 5s. at each of the three examinations); C.M., £5 2s. (in addition to the fees of M.B.); M.D., £5 5s. (in addition to the fees for M.B.); and £10 3s. for Government stamp.

*University of Edinburgh.*—This is a teaching as well as a qualifying body, and the other faculties are as complete as that of Medicine. The University confers the degree of M.D. and M.B., as well as that of C.M., and also affords its graduates the opportunity of obtaining, at the same time, a surgical, in addition to the medical diploma. The C.M. is not conferred on any one who does not take at the same time the M.B. For the degrees of M.B. and C.M. four years of professional study must be completed after passing a preliminary examination recognised by the Medical Council. A degree in Arts in any British University exempts from the preliminary examination. Of these four years one must be passed in the University of Edinburgh, and one other either in that or some other University entitled to confer the degree of M.D.

The University recognises the course of lectures of extra-academical teachers in Edinburgh, subject to certain regulations.

*University of St. Andrews.*—This University confers the degree of Master in Surgery (C.M.), as well as the degrees of Bachelor and Doctor of Medicine. Residence in one of the Scottish Universities is required, but an exception is made in favour of ten persons yearly.

*University of Aberdeen.*—This is a large teaching body, as well as one entitled to confer degrees in all the faculties. The curriculum required for medical degrees is the same as that of the University of Edinburgh. Thus, four years of professional study, after passing a preliminary examination, is essential. One year must be passed at Aberdeen. The lectures qualifying for this and other examining bodies are delivered by the Professors in the University.

*University of Glasgow.*—This is a large teaching as well as an examining body. The same degrees are conferred as in the Universities of Edinburgh and St. Andrews. The course of study and regulations to be observed by candidates are the same as those of the University of Edinburgh, one year's compulsory residence at the University of Glasgow being required instead of at Edinburgh. The examinations are conducted by the Professors of Medicine, together with the three Assessors appointed by the University Court. The lectures qualifying for the degrees are delivered by the Professors in the University, and the hospital practice is attended at the Glasgow Royal Infirmary.

## THE COLLEGES.

*Royal College of Physicians of Edinburgh.*—This, like its London sister, is exclusively a licensing body, though, since the arrangement for the double qualification has been carried out, it may possess some additional control over the teaching at Surgeons' Hall. By this arrangement students who have filled the prescribed curriculum may pass the joint examination of this College and the Royal College of Surgeons, and obtain the two diplomas. They can thus at once register both a medical and surgical qualification.

The Fellowship is conferred only by election, and no one can be balloted for until he has been a member for one year, and has attained the age of 25.

The Membership is conferred on licentiates of a College of Physicians, or graduates of a University, who are twenty-four years of age, and satisfy the College of their knowledge of medical and general science.

The Licence.—The regulations are nearly the same as those for the Joint Examination for the Scotch Double Qualification.

The fee payable by a licentiate is £10 10s.

The fee to be paid by a member is £31 10s. When a licentiate is raised to the rank of a member he pays £21. When a member is raised to the rank of a fellow, the fee is £31 10s., exclusive of stamp duty, which amounts to £25. All candidates for fellowship or membership must lodge their fees, and the amount of stamp duty payable at the time to Government, with the treasurer, previously to presenting their petitions.

*Royal College of Surgeons of Edinburgh.*—Candidates for a surgical diploma must have followed a course of study in a university, or in an established school of medicine, or in a recognised provincial school.

*Preliminary Examination.*—All who intend becoming candidates for the diploma of the College must have passed the complete examination in general education as prescribed by the General Medical Council, and have had their names inscribed in the Register of Medical Students at the commencement of their professional studies. Testimonials of proficiency granted by educational bodies recognised by the Medical Council exempt students from the Preliminary Examination.

*Professional Education.*—Candidates commencing professional study must have been engaged, during four years after the examination in general education, in professional study, which shall include not less than four winter sessions, or three winter and two summer sessions' attendance at a recognised medical school.

*Professional Examination.*—Candidates are subjected to two Professional Examinations, conducted at separate sittings, partly in writing and partly orally.

The First Examination embraces Anatomy, Physiology, and Chemistry.

The Second Examination embraces Surgery and Surgical Anatomy; also Medicine, Midwifery, Materia Medica, and Medical Jurisprudence; and does not take place before the termination of the winter session of the last year of study.

The Fellowship is conferred only on persons who have obtained a diploma from this or one of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, and who are twenty-five years of age. At the election, three-fourths of the votes are required to be in the candidate's favour, and he has to promise to maintain the privileges of the College and obey its laws. Fellows are forbidden to keep open shops, to be connected with secret remedies, or to suffer their names to be used in indelicate advertisements or publications.

The Licence.—The regulations are nearly the same as those for the Joint Examinations conducted by the Colleges of Physicians and Surgeons.

## THE SCOTCH DOUBLE QUALIFICATION.

As already stated, the Royal College of Physicians of Edinburgh has made arrangements with the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, by which, after one series of examinations, the successful candidate receives two diplomas, and is thus able to register a medical and a surgical qualification under the Medical Act, thus :—

Lic. Roy. Coll. of Phys. Ed., and Lic. R. C. S. Edin., or Lic. R. Coll. of Phys. Ed., and L. Fac. Phys. and Surg. Glas., as the case may be.

The principle on which the joint examinations are conducted is a simple compromise by which the College of Physicians takes exclusive charge of the examination in medicine; the College of Surgeons or the Glasgow Faculty, as the case may be, of the examination in surgery; while the examination in subjects common to both medicine and surgery is conducted by a board, in which each of the bodies is represented.

It is proper to state that such arrangements as these were contemplated by the Medical Act and authorised by Section XIX., while those under consideration were sanctioned by the Medical Council on the 7th August, 1859.

Candidates for the double qualification having fulfilled the prescribed curriculum are subjected to two professional examinations. The preliminary examination for future students must be passed before commencing professional study, and in other respects be in accordance with the recommendations of the Medical Council.

*School of Medicine, Edinburgh.*—The lectures qualify for the University of Edinburgh and the other universities, the Royal College of Physicians and Surgeons of Edinburgh, London, and Dublin, and the other medical and surgical boards.

In accordance with the statutes of the University of Edinburgh, any four of the medical classes required for graduation, or two complete *anni medici*, may be attended in this school, each of which *anni medici* may be constituted by attendance on two of the six months' courses, or on one of these and two three months' courses. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University.

The whole of the education required for graduation at the University of London may be taken in this school.

The minimum cost of the education in this School of Medicine for the double qualification of physician and surgeon from the Royal Colleges of Physicians and Surgeons, including the fees for the joint examination, £90 4s., which is payable by yearly instalments during the period of study; whilst the minimum cost for the single qualification of either physician or surgeon, including fees for examination, is £80.

*Royal Infirmary, Edinburgh.*—Clinical instruction is given by the professors of the University of Edinburgh and also by the ordinary physicians and surgeons. Special instruction is given on diseases of women, physical diagnosis, and on diseases of the eye. Separate wards are devoted to fever, venereal diseases, diseases of women, diseases of the eye, &c. Perpetual fee, in one payment, £10; annual, £5 5s.; half-yearly, £3 3s.; quarterly, £1 11s. 6d. Separate payments for two years entitle the student to a perpetual ticket. No fees are payable for any medical or surgical appointment. These appointments are—Four resident physicians and four resident surgeons, who live in the house free of charge. Non-resident clinical clerks are appointed by the physicians and surgeons. Each surgeon appoints from four to nine dressers, the appointment being for six months. Assistants in the pathological department are appointed by the pathologist.

*Anderson's University, Glasgow.*—This is exclusively a teaching body. It offers excellent opportunities for acquiring a complete medical education, and the expenses are very much below those of any other institution. The fame of Glasgow as a place for clinical instruction has long been known, and this school affords the means of dissection, and the pursuit of other practical knowledge throughout the year. Hospital practice is attended at the Glasgow Royal Infirmary.

*Faculty of Physicians and Surgeons of Glasgow.*—This body has similar powers to those of the Royal College of Surgeons of Edinburgh, and its regulations for licence and fellowship correspond. It has also the same arrangement

with the Edinburgh College of Physicians for a double diploma. Preliminary examinations will be conducted by the Faculty in October, 1874, and in April, July, and October, 1875.

**THE STUDENTS' NUMBER.**—In the preceding columns we have endeavoured to present in as small a compass as is consistent with accuracy and utility a guide to those about to enter the various Medical Colleges of the United Kingdom for the first time; and also for those who, having gone through the recognised curriculum, are seeking entrance into our profession. In our task we have been ably assisted by several gentlemen, and also by the Deans of the various schools, who supplied us with all necessary information, to all of whom we tender our warmest thanks.

## Medical News.

**DEATH OF DR. ANSTIE.**—Death has claimed another victim from the foremost ranks of the profession in the person of Dr. Anstie, Physician to the Westminster Hospital, and well known by his writings on hygiene and therapeutics, and as editor of our excellent contemporary *The Practitioner*. Several cases of severe illness having occurred in the School of the Royal Patriotic Fund, at Wandsworth, Dr. Anstie was called in to advise as to the causes and means of prevention, as well as to the treatment of the sufferers. With a disregard of principles which he would most strenuously have insisted upon in others, he spent several hours on Sunday, the 6th inst., in these investigations, exposed to sewer-gas, and resumed them on Tuesday, the 8th. In the evening of that day he complained of being unwell, and, notwithstanding the unremitting attention of his friends, Dr. George Johnson and Dr. Burdon Sanderson, he died on Saturday of blood-poisoning, occasioned primarily from a puncture in the hand whilst engaged in a post-mortem on one of the pupils.

**HOSPITAL OUT-PATIENT REFORM.**—At a meeting of medical men called to consider this question on Friday last, it was moved by Dr. Ford Anderson, seconded by Dr. Joseph Rogers, and unanimously resolved :—“That, seeing that Poor-law dispensaries have been established throughout the metropolis whereby the wants of the indigent classes are fairly met, and that several provident dispensaries also exist, which, properly supported, would meet the requirements of those above them, this meeting considers that the time has arrived when the out-patient departments of the London hospitals may be materially curtailed with advantage to the community, and therefore urges on the subscribers to such hospitals the advisability of supporting a reform in this direction.”

**PRELIMINARY EDUCATION.**—Under the title of “Via Medica,” Dr. J. Baxter Langley has issued a work of great utility to the student; the chapters upon preliminary education are especially valuable, and the laws and customs of the profession are treated upon at great length. As may be presumed, the duties of the office of assistant in private practice are very various, and the relations between principal and assistant very complex. The book is published by Messrs. Baillière, Tindall, and Cox, a fourth edition of which is, we understand, in preparation.

## Marriages.

**MARSHALL—WARWICK.**—On the 8th inst., at St. Jude's Church, Englefield Green, Surrey, John James Marshall, L.R.C.S.I., &c., of Lambhurst, Kent, to Mary, eldest daughter of Benjamin Warwick, Esq., Englefield Green.

**BAKER—FENE.**—On the 10th inst., at Hargrave, Northamptonshire, Thos. Young Baker, Staff Surgeon, M.D. (late of the 57th Inniskilling), to Emily Augusta, only child of Lincoln Fene, Esq., of Leamington.

**HUNTER—PAINE.**—On the 9th inst., at St. Mark's, Myddelton Square, Dr. W. J. Hunter, fourth son of J. Hunter, Esq., of Kilrea, Ireland, to Anne, eldest daughter of H. Paine, Esq., of Clackgawell.

## Deaths.

- BATES.—On the 9th September, at his residence, No. 6 Stockport Road, Ardwick, Manchester, William Bates, M.D., F.R.C.S., aged 55.  
 BOWDAGE.—On the 6th September, at Wiveliscombe, Somerset, E. Bowdage, M.R.C.S., formerly of Crewkerne, aged 74.  
 CARTE.—On the 10th September, at Somerset Street, Portman Square, Edward Elliott, elder son of John Elliott Carte, M.B., C.B., Inspector-General of Hospitals, in his 15th year.  
 CUTLER.—On the 7th September, at New Burlington Street, London, Edward Cutler, F.R.C.S., &c., aged 77.

## Cleaning.

## Toxicology.

*Poisoning by Arseniuretted Hydrogen.*—Nine cases of poisoning by this gas (three of which were fatal) are reported in detail in the *Vierteljahrsschrift für Gericht. Medicin* (April, 1873) by Dr. Frost. These cases add materially to our knowledge of poisoning by this form of arsenic, since there are so few cases on record.

These persons were poisoned by inhaling the gas which was set free in a new process for extracting silver from metallic lead.

Some of the workmen were affected on the first day, others not till the second. All who were engaged in the operation of stirring were affected.

Those who recovered were affected during the first two days with loss of appetite, nausea, dizziness, gaseous eructations, sweet taste in the mouth, tremendous pain in the limbs, yellow appearance of the skin and conjunctivæ, narcotic sleep, from which the patient could be roused quite easily, a sensation of weariness in the legs, bloody urine and bloody stools. On the third day, the patients were found in a deep sleep, with jaundice, high temperature, pulse 100 and more, difficult respiration, tongue dry, and covered with a white coat. On being roused, the patients complained of an intense pain in the head, a dirty taste in the mouth, great thirst, and excessive pain during micturition. The somnolent condition lasted about five days; the pain during micturition lasted three or four days, when the urine gradually became free from blood, and the jaundice began to disappear in four or five days. The patients were confined to their beds for two or three weeks, and could not resume work for several months.

In the fatal cases, the same sensations in the limbs were perceived, and there were, also, headache, nausea and vomiting, fluid stools, bloody urine, jaundice, small and rapid pulse (150–160), delirium and stupor, from which the patient could be roused, and death, which took place in one case in a little more than twenty-four hours after the commencement of the symptoms, in another in about two days, and in the third case in five and one-half days.

At the autopsy, a dirty yellow colouration was noticed in the skin and all of the tissues. In one case, a garlicky odour was evolved from the fluid which flowed from the mouth and nose; a thin layer of bloody serum covered the arachnoid; the large vessels contained a little dark blood; the kidneys were congested, and dark-red in colour, and the bladder was empty, or nearly so. In one case, a patch of the mucous membrane of the stomach, about two inches square, upon the posterior surface had a dark grey appearance, and was easily raised from the sub-mucous tissue.

Arsenic was detected in all of the tissues and fluids which were submitted to analysis, in the stomach, blood, fluid which flowed from the mouth, kidneys, heart, lungs, and bronchi. Arsenic could not be detected in the urine of one of the patients who recovered.

*Acute Poisoning by the Chromate of Lead.*—Two fatal cases of acute poisoning by chrome yellow are reported in the *Vierteljahrsschrift für Gericht. Medicin* (Jan., 1874) by Dr. von Linstow. These cases occurred in children, aged respectively 1½ and 3½ years, and the poisoning was caused by sucking an unknown number of small, yellow substances, which had been used for ornamenting pastry, and which consisted of gum tragacanth and chrome yellow.

Chromate of lead, on account of its insolubility, has never been considered an active poison, and the fact that it is used so largely as a pigment for colouring not only ordinary substances, but also children's playthings, and even articles

intended for food, such as confectionery, &c., renders these cases of more than ordinary interest. The extent of its use in confectionery can be seen by an examination of the report of analyses of confectionery, by H. B. Hill (*Mass. State Board of Health Report*, 1873, p. 390). Thus 77 samples, both white and coloured, were analysed: 21 were coloured yellow, and in 17 of these the pigment consisted entirely of chrome yellow, in 2 partially; of 12 specimens which were of an orange colour, the pigment in 9 consisted entirely of chromate of lead, and in 2 partially; 7 specimens of green were examined, 6 of which contained chrome yellow mixed with Prussian blue in five specimens, and with Scheele's green in the other. Of the 77 specimens examined, 36, therefore, contained the chromate of lead.

The symptoms of poisoning did not commence until several hours after the ingestion of the chrome yellow, which took place between 9 and 11 a.m. Both children were taken sick at the same time (between 2 and 3 p.m. of the same day) with vomiting, which lasted for several hours. The vomitus was yellow in colour. There was great prostration and extreme thirst, but no diarrhoea and no pain. On the second day, both had a hot and red countenance, and were stupid. The younger, about twenty-four hours after the commencement of the symptoms, had a slight diarrhoea and convulsions, which continued until death, which took place in forty-eight hours. On the third day an erythematous eruption appeared on the chest and abdomen of the elder. He was dull and stupid, and the temperature in the axilla was 39.5°C. On the fourth day, the pulse and respiration became irregular, the breath extremely fetid, stupor and unconsciousness came on, and the patient died five days after the ingestion of the poison.

After death the mucous membrane of the stomach and duodenum was found swollen and loose, so that it could easily be raised from the sub-mucous tissue; it was inflamed, as was also that of the œsophagus, throat and larynx. In some places, the mucous membrane of the stomach and duodenum was entirely destroyed, and in one spot perforation had taken place showing that the chrome yellow had a corrosive action. These appearances were probably not caused by the chromate of lead, as such, but by soluble compounds formed after the pigment had lain in the stomach some time, and had been decomposed.

Besides the above appearances, there were found also hyperæmia of the brain and its membranes, beginning fatty degeneration of the liver, commencing icterus, hyperæmia of the kidneys, suppurative pyelitis, and a softened spleen; conditions which are often seen after death from poisoning by other corrosive poisons.

The number of these yellow ornaments ingested by the children could not have been more than six, since only seven were given them to play with, and one was afterwards recovered. If each child had eaten three of these, the fatal dose was less than 0.01 grm., or between  $\frac{1}{2}$  and  $\frac{1}{3}$  of a grain of the chromate of lead.

*The Action of Alkaloids on Albuminoid Substances.*—By M. Y. Rossbach (*Neues Repert. für Pharm.*, xxii. 512-544).

Experiments were undertaken to explain the action of the alkaloids in diminishing the oxidation in the body, and it was found that, by the addition of neutral salts of the alkaloids (salts of quinia, strychnia, veratria, morphia and atropia were used) to solutions of egg albumen, the temperature required for the coagulation of the latter was lowered very much; that solutions so dilute that no turbidity was produced by boiling the aqueous solution became turbid at 59°–62° C., when a trace of a neutral salt of an alkaloid was present; that more turbidity was produced by heating solutions of albumen if an alkaloid were present than with the simple aqueous solution; and that this altered coagulability is due to a true chemical combination taking place between the alkaloid and the albumen. The compound formed has the properties of an alkaloid. No combination takes place between 1° and 10° C.

The same results were produced with the blood serum, and the juice of muscle, and it is concluded that dissolved albumen is converted by the alkaloids into a less soluble substance, which is a compound of albumen with the alkaloid.

The alkaloids were also found to unite with hæmoglobin, but they do not prevent it from acting as an ozonizer. They do, however, seem to bind the oxygen more closely to the hæmoglobin, so that it is not given up so readily to other bodies.

## A Course of Lectures

ON THE

### NATURE AND TREATMENT OF DEFORMITIES OF THE HUMAN BODY,

DELIVERED IN THE MEATH HOSPITAL, DUBLIN, BY

LAMBERT H. ORMSBY,

Surgeon to the Hospital, and Demonstrator in the School of Surgery, Royal College of Surgeons in Ireland.

#### LECTURE VII.

#### DEFORMITIES AND DISTORTIONS OF THE SPINE.

*Introduction—Number of Works published on the Subject—Great Difference of Opinion as regards Causes and Treatment—The Mistake that is made by keeping entirely to one Line of Treatment—The Anatomical and Physiological Features of the Vertebral Column—The Curves of the Spine—The Spine studied as a Wonderful Piece of Mechanism—Anterior, Posterior, and Lateral Curvature: Causes, Symptoms, and Treatment—Mechanical and Non-Mechanical Method—Conclusion.*

IN the whole scope of medical and surgical literature, I suppose no subject has received so much attention as the subject before us. Judging from the number of works, monographs, lectures published from time to time on curvature of the spine, and spinal distortions generally, the fact of the matter is, that every surgeon taking up the subject of orthopedic surgery as a speciality thinks it is necessary and required of him to write some treatise, or communicate his ideas in some published form, as from his experience and study, directed, as it must be, constantly in one direction, it is most likely he will, firstly, by practical demonstration, and secondly, by reflection and mature consideration, arrive at views more true and practical as to the causes of such distortion, and more useful as regards the treatment of such cases than those who are engaged more in general practice. In this, like many other subjects that have been repeatedly written upon, various authors who have laboured with great assiduity in the same path differ

considerably in their ideas and theories of not only the causes of distortion, but also in a very wide degree as regards the treatment; and I can quite well understand the feelings of difficulty and doubt which would naturally fill the mind of one not very conversant with the treatment of such cases, but happening to meet with an isolated one in practice, and wishing to treat it for information's sake, consults two authors diametrically opposed in view and treatment to each other; for, unfortunately, in my opinion, authors are too positive as regards the efficacy of the principle they promulgate, and rather inclined to make more of the advantages of such and such a plan of treatment than frequently really exists; and not only that, they are so wedded to their own method that any other in their hands is scientifically incorrect, and in some cases are not very sparing or complimentary in their remarks of disapproval, and decry in the strongest manner any plan differing from their own. This, after all, may seem very trivial in detail, but, at all events, it cannot do much in a scientific point of view, or practically benefit cases, or enlarge the information we wish to possess on this important subject. To educate our minds with the idea that there is but one settled undeviating line of treatment, suitable with slight modifications for all classes of cases, must seem to the most common-sense person who reflects at all as perfectly erroneous, for I have before-mentioned, when talking of other deformities, that each case stands on its own basis, and, whether in circumstances, history, or present symptoms, always differs slightly from other comparatively similar cases, and as the symptoms differ, so must the treatment vary, and a fair trial of all modes and plans recommended sometimes produces the happiest results.

To aid you in studying the abnormal curves the spinal column sometimes assumes, I conceive that a brief anatomical description of the normal physiological curves would not be out of place.

The vertebral column is the foundation and framework of the whole skeleton; at its summit, most beautifully poised, is the cranium; from its side we have the ribs articulating; and below it is substantially supported by the sacrum and bones of the pelvis; it is composed of a series of articulating bones called vertebrae, twenty-four

in number, connected by strong ligaments and fibro-cartilage, allowing of slight motion as regards each other, but of considerable flexibility as regards the spine as a whole. This flexuous bony column is not only a pillar of support, but also affords protection to the spinal cord, which it encloses in a perfect osseous canal, thus defending it from injury on all sides. These twenty-four vertebrae are beautifully arranged one above the other, with thin plates of fibro-cartilage, called intervertebral substance, interposed between the bodies of each, to act as "buffers," to prevent and break any shock that may be received at either extremity of the column; these vertebrae admit of motion, and remain ununited to an advanced period of life, though they may become ossified at a much earlier period by disease or other causes. These are placed on the sacrum, which is composed of five bones, at one time perfectly separate, but in adult life all fused together to form a triangular-shaped bone, tapering from above downwards, to the inferior extremity of which the coccyx is united, which was composed of four separate bones, but as age advances are perfectly united to each other, and also to the sacrum. The length of the spine varies, but on an average it measures about two feet three or four inches, and is somewhat proportionate to the height of the individual. Viewed from above downwards with a cursory glance, this column appears to be divisible into two well-marked pyramids, joined together at their bases, the upper one beginning from the second cervical to the sacrum, the lower one commencing at the sacrum and ending at tip of coccyx. The upper pyramid, on examining it more closely, can be divided again into three more—viz., 1st, beginning at second cervical, which is the apex, and ending at last cervical; 2nd, beginning at first dorsal and ending at the fourth dorsal (this pyramid is inverted); 3rd, beginning at fourth dorsal and ending at last lumbar. This division is artificial; but on close examination the spine has a certain amount of natural division; so far as it increases and diminishes in size at those stated points it may also have some practical importance about it, for where the spine is smallest, so is it weaker, allows of greater mobility, and more prone to distortion and disease, which is in the middle dorsal region, motion being greatest in the cervical and dorsal region, and very limited in the lumbar region. On again viewing the spinal column from cranium to coccyx, we find it divisible into four well-marked physiological curves—viz., the cervical, dorsal, lumbar, and sacral. These curves have great practical importance, for in many cases an abnormal curve is nothing more than a great increase of the physiological curve in the situation.

There is a difference of opinion as regards the causes of these physiological curves; some anatomists assert that it is naturally essential that the bony column should have these curves, and is a great provision of design for the purpose of supporting the superincumbent weight of the head and shoulders, and also acting as species of elastic and flexible springs, by frequently changing the line of gravity from the upper part of the body to the lower extremities; it is also due to the thickness of the bodies of the vertebrae and the intervertebral fibro-cartilaginous substance in the different situations, and the tension and elasticity of the spinal ligaments, together with contraction and action of the muscles, which must be in action when the body assumes the erect posture. In infants these curves are not required, as they are so constantly lying in the horizontal position, but as they advance in growth and years these curves become gradually developed, convex forwards in the cervical region, concave forwards in the dorsal region, convex forwards in the lumbar region, and concave forwards in the sacral region. It seems as if naturally one curve produces a compensating curve; so the same thing is found to occur in the curvatures of disease. The measurements of the curves are calculated as follows:

The cervical curve having 28 degrees of a circle and  $6\frac{1}{2}$  of a radius, beginning at the odontoid process and ending at about the second dorsal vertebra.

The dorsal curve having 42 degrees of a circle and

$12\frac{1}{2}$  of a radius, beginning at second dorsal and ending at lower edge of eleventh dorsal vertebra.

The lumbar curve having 80 degrees of a circle and  $5\frac{1}{2}$  radius, beginning at the middle of the last dorsal and ending at last lumbar vertebra.

As I said before, that these curves are not present in infants, but become gradually developed as the infants advance in years, is a fact; but they are seldom placed in the position to develop those curves, that is, in the erect posture. Examine an adult patient lying on his face, and the curves will not be so apparent, which proves that the muscles, ligaments, and superincumbent height exert a powerful influence in producing such curvatures, at the same time they are made a more necessary requirement as the important viscera in the thoracic, abdominal, and pelvic cavities become developed and require space for further development. If a small thin piece of flat steel be held in the hand and the weight of the hand applied to the superior extremity, and the other extremity placed on a firm resisting block, the pressure will cause the steel plate to assume various curves either backwards or forwards, and if the pressure be applied with the steel plate held laterally a lateral curvature will be produced. Surely such an easy experiment, though simple as it may appear, explains to a certain extent how abnormal curvatures are produced from disease.

The spine, as a piece of mechanism, is certainly most wonderful, and should ever be the source of great admiration to the thoughtful anatomist when he considers the number of important offices it fulfils in the most perfect manner. It is strong enough to support and preserve the erect position of the body; it is flexible to allow the body to assume such a varied number of attitudes; and has in itself an inherent power by its flexibility and elasticity to regain its normal position when required; its strength also depends on the peculiar way in which each vertebra is joined to the other, and the great importance of the intervertebral fibro-cartilage, which is for the purpose of breaking shocks, which would naturally act most injuriously to the brain if transmitted by a continuous rigid bony column; also the curves are found to increase the strength of the column, and allows it to bear a greater amount of superincumbent weight; it protects the spinal cord free from injury in the most perfect manner, and this spinal canal gives lightness without diminishing strength, as found in other bones of the body. There is a natural lateral curve which we find in the middle of the dorsal region, with its concavity to the left side. Some anatomists assert it is caused by the pulsating action of the thoracic aorta; others say it is due to the action of the right arm, which is more often used than the left. With such remarks, by way of an introduction, we may, without further observations, consider the abnormal conditions of the spine.

(To be continued.)

## REPORT ON SYPHILIS.

By C. R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.,  
Senior Physician to the Metropolitan Free Hospital.

### DR. FOURNIER ON THE DIAGNOSIS OF TERTIARY SYPHILITIC AFFECTIONS OF THE GENITAL ORGANS.

In a lecture delivered at the Lourcine Female Venereal Hospital of Paris (*France Méd.*, August 8th, 1874) Dr. Fournier thus speaks:—

The affections we have just described by the name of genital tertiary syphilitic affections present several objective resemblances with a certain number of lesions which are quite foreign to them. These resemblances may even be so well marked in certain cases as to give rise to errors in diagnosis easily to be made.

Now, these errors here may cause consequences of two kinds:

On the one hand, regrettable practical consequences;

one lesion is taken for another, and the treatment of the latter is applied to the former. On the other hand, doctrinal consequences, which, as a species, are of greater importance, because they conduct either to mistakes as to the characters that are symptomatic, or about the evolution of such or such a venereal type, or even to the assimilation of opposite pathological types.

You will soon see what I am now alluding to.

Well, it is a curious fact that the two morbid entities with which tertiary syphilitic affections of the genital organs run the most risk of being confounded are the two species of lesions commonly designated by the name of chancre—namely, the simple chancre and the syphilitic chancre.

It is then, first of all, with the simple chancre and the syphilitic chancre that we must make the differential diagnosis with the lesions we are now speaking of.

Let us first speak of the simple chancre. Here, gentlemen, the error is easily committed. Certain ulcerated syphilitic affections, indeed, simulate the simple chancre in a surprising manner: to such a degree that the differential diagnosis is often very difficult to establish between these two lesions.

Of all venereal accidents, I state it as a fact that there are no two which are more alike in certain conditions than tertiary ulcerating syphilitic affections and simple chancres.

The distinction of these two diseased types is not only a problem hard to solve, it is—and I do not exaggerate in saying so—the most difficult problem in syphilography. There is not, assuredly, in all syphilis, a point more delicate and embarrassing than this.

Indeed, there are numerous reasons why this error should be committed. Observe how many common features there are between these two lesions, the simple chancre, and ulcerating tertiary syphilitic affections.

Firstly, identity of position, very habitual localisation of these two lesions on the same point on the genital organs.

In the second place, incontestable analogy of the apparent objective symptoms between these two lesions: in both, lesions consisting in ulcerations more or less hollowed out, attacking the cutaneous or mucous derm; generally rather circumscribed; equally susceptible of extension; suppurating rather abundantly; sometimes having no effect on the glands, &c., &c. There is, very evidently, an analogy of objective characters, well fit to deceive us, and excusing errors in many cases.

On what basis, however, can we attempt to institute a differential diagnosis between these two orders of lesions? By four orders of symptoms, which are the following, and which have not all, as you will see, an equal value.

1. *Objective Characters.*—The simple chancre has, in general, more abrupt edges, sharper, more neatly and vertically stamped out than those of the ulcerated tertiary affection.

The simple chancre presents an areolar and chequered base; the ulcerated syphilitic affection presents a base smoother and more even.

The simple chancre has a yellower colour than the tertiary ulcer, which is yellowish, grey or reddish.

Such characters, to be justly appreciated, require a certain familiarity with venereal diseases, an exercised eye; for it must be confessed, there are differences only of more or less objective shades, rather than differential symptoms properly so-called.

2. *Second Sign.*—Simple chancres are generally more multiple, and especially surrounded at their circumference with simple chancres smaller in size, commencing, and consecutive, developed by neighbouring inoculation, whilst there is absence of the like peripheral lesions in ulcerated tertiary syphilitic affections.

Do you, indeed, remember gentlemen, what I said to you last year about the simple chancre? It is a chancre which is eminently contagious, and the pus of which infects all it touches. When not dressed, this chancre produces around it new chancres, by inoculation of the neighbour-

hood. The simple chancre—pardon me the expression—makes little ones around it, and these new chancres, when born, and young, are necessarily less advanced in their evolution, less large, shallower than the parent chancre, the adult chancre which has begotten them. This is what made M. Ricord say that the simple chancre “lives in the family, surrounded by its young.” Nothing of this kind naturally occurs with the ulcerating syphilitic affection, which is not inoculable, and does not produce any consecutive lesions around it; it makes no *little ones* on the zone of tissue around it.

There thus exists a differential sign very easily appreciable and very characteristic. When this symptom exists it is final, and the diagnosis profits by it. But it does not always exist, because there are some careful patients who dress, isolate, and sequester the chancre as soon as it appears, and who thus take away its powers to cause fresh ones in its neighbourhood. This is an excellent symptom, in short, but not a constant one.

3rd. *Condition of the Glands.*—With the simple chancre one of two things happens—either there is complete absence of enlargement of the glands, or there is a bubo, acute, isolated, inflammatory, acutely inflammatory, most frequently suppurating, and sometimes degenerating into a true glandular chancre. With these other syphilitic ulcerations there is no enlargement of the glands, at least in the enormous majority of cases.

This is, again, a good symptom to look for, but inconstant, since in the two cases the affection of the glands may equally be wanting.

4. *Inoculation.*—Lastly, when the collective symptoms preceding do not suffice for diagnosis, inoculation presents itself as the last analysis, and it presents itself with perfect guarantee for truth; it offers a formal criterium, absolute and clearly marked.

Thus, with the simple chancre there is positive inoculation, never wanting if the experiments have been well conducted; with the ulcerating syphilitic affection the inoculation is negative.

It is to inoculation that we are forced in certain cases to have final recourse, when we have interest in making a formal diagnosis, and it is that, and that alone, which gives certainty in such circumstances. Unfortunately, we have not always the power of trying the experiment, either because the patient refuses, or that we fear for the results. Besides, in practice, even in these cases of doubt, it is not always indispensable to have recourse to inoculation, for the treatment of the two lesions, is almost the same; at any rate, what suits locally the one cannot hurt the other; and as to general treatment, the phenomena which have preceded the lesion suffice, with rare exceptions, to decide whether there is need or no to administer it.

I have just insisted at length, at great length, on the differential diagnosis of the ulcerative syphilitic affection and the simple chancre. Is there, then, gentlemen, such an important interest in differentiating these two orders of lesions? Yes, certainly there is. This differential diagnosis has a great interest, a capital interest, an enormous scientific interest, shall I dare to say so?

And why? Judge of the consequences which may result, and which necessarily result from the confusion made between these two diseases.

What are these consequences?

First, there are symptomatic errors, consisting in this: characters of a syphilitic accident applied to the simple chancre and reciprocally. It is, for instance, thanks to such errors, that persons have accorded to syphilitic lesions the faculty of determining auto-inoculations of a positive kind, so as to produce the simple chancre by inoculation, to determine suppurating buboes with inoculable pus, chancrous pus &c. . . . all properties which, you know, belong only to the simple chancre, and essentially characterise the simple chancre.

As other consequences, there are also errors as to the mode of transmission of the viruses, in experiments with inoculation or in researches on the confrontation of patients. For instance, suppose an ulcerative syphilitic affection

transmits a contagion : what it transmits will necessarily be syphilis. Now, suppose that it have been mistaken as to its nature, and taken for a simple chancre—it will appear in these conditions to have transmitted syphilis, although not of syphilitic nature, and the confused observer will register this : syphilis transmitted by a simple chancre.

Now, this error is not in the condition of simple hypothesis ; it has been made and made again several times. I accuse myself as among the first to have committed it, and even to have printed it, when I was not so enlightened about the existence of these ulcerating syphilitic lesions, which may put on the aspect of simple chancre.

And what is, gentlemen, the consequence of the errors thus committed with regard to symptomatology. It is nothing less than the confusion of these syphilitic affections with the simple chancre ; the assimilation of the simple chancre with syphilitic accidents ; the reintegration of this among the symptoms of syphilis—that is to say, the dualistic doctrine denied and misunderstood, refuted by material errors and clinical mistakes ; the syphilitic chancre misunderstood as regards its morbid entity ; the unicist doctrine restored, although it only states an error ; the labours of a whole generation, of Ricord, Bassereau, and others called in question ; conquests of modern science, especially of the French school, abandoned and sacrificed ; and, in short, scientific relapse, relapse towards the errors of the past, which were justly warred against. Such is the result to which the confusion of ulcerated syphilitic affections has conducted ; and these results explain to you, gentlemen, whether I ought to insist before you on making this a capital point in our science or no.

*Syphilitic Chancre.*—Another diagnosis, and that a most unexpected one, next presents itself for discussion. Tertiary syphilitic affections—do not be astonished—may be confounded with the *indurated chancre*.

Of course, it is not every tertiary syphilitic affection which, indifferently, may be confounded with the indurated sore ; it is only certain of these which, in given conditions, approach a good deal in objective symptoms to the initial symptom of syphilis, so as to run the risk of being confounded with it.

And, first of all, gentlemen, do not imagine that I am imagining a difficulty between two diseased conditions very distinct in character, or that it is a forced approachment that I am making for pleasure—a theoretical confusion which could not be practically made. Far from it. The diagnosis we are about to discuss is one of those met with in *practice*. The confusion I am about to point out is among the number of those which are easily committed, and which have been committed more than once. On several occasions tertiary syphilitic affections have been taken for indurated chancres, and this error, indeed, is very difficult to avoid in certain cases, as you are about to see.

But how, then, can tertiary syphilitic affections be taken for indurated chancres, and, above all, what are among them the ones which lead to such confusion ?

The tertiary syphilitic affections, which come near enough to the indurated sore to be mistaken for it, are those which are at once circumscribed, indurated, and solitary. By this triple character, indeed, they have a marked analogy with the infecting chancre, which has for its habitual attributes, as you know, the being a lesion generally circumscribed, indurated at its base, and solitary.

There are some tertiary syphilitic affections which present themselves with this triple attribute with this triad of accidents.

Remember, in fact, gentlemen, these curious lesions of the penis, of which I spoke to you at our first réunion, and which commence by a small dry callus, to terminate by ulceration of this callus. I told you that these little tumours have a character of being generally well circumscribed, very clearly limited, and of forming in the midst of a healthy tissue knots of induration of a rounded form, usually of smallish size, comparable to an hazel-nut on an average. I added that these tumours were often solitary ; that they occupied most habitually the fold of

the gland and prepuce ; that after resting in the state of dry indurations a certain time they afterwards ulcerated, whilst they remained indolent, inflammatory, indurated, &c.

Well, do you not find in this the collection of characters required to establish between these lesions and the simple chancre an apparent analogy ?

It is in this way that certain gummy tumours of the genital organs take on the appearance and marks of the indurated sore, and resemble it enough to create a very simple confusion between these two lesions. These gummy tumours are true indurated chancres apparently to the eye. They look strangely like them at first sight, and the more as we analyse their different symptoms. And in this way I think they well deserve the name of pseudo-indurated chancres, under which I long ago described them, with the desire of calling attention to them, and of pointing out the kind of errors to which they may give rise.

If this be the case, if certain tertiary syphilitic affections may be so like the indurated sore as to be confounded with it, it is then important, and important for various reasons, as you will soon see, to seek how these lesions may be distinguished. Let us, then, see what signs permit us to differentiate them.

Is it firstly in the objective symptoms, in the external characters of the lesion, that we shall find the elements of this diagnosis ? Not at all, since the property of these accidents which we are speaking about is to assume the characters and physiognomy of indurated sores.

All that we should here find, in attempting to give in detail the minute characters of the lesions, would consist in shades but little significative, such as the following : Ulcerating syphilitic affections presenting edges less abrupt and less sharply cut than the chancre ; a more elastic base, and less evidently cartilaginous than true induration ; a base more yellowish, less brown, and differing from the tint of muscle which so frequently characterises the syphilitic chancre, &c., &c. But there would only be very secondary symptoms, and besides, requiring caution.

A better sign, and indeed, a good one, may be borrowed from the initial form of the lesions.

The chancre, in fact, commences by an erosion which indurates ; tertiary lesions which resemble them commence by indurations which ulcerate. The pathological process is, then, reversed in the two lesions.

But it is very rare that we arrive soon enough to discover this evolution, which, if well and duly observed, would be characteristic. We have only to judge of it, the information and observation of the patients, and on this very delicate point the observation of patients is more than subject to error. Most frequently, then, nothing is to be got from this particular sign.

The elements of the differential diagnosis we are studying are not, or very rarely are to be found in the two preceding considerations. They reside elsewhere, if they exist. Where are they ?

In my opinion, and all things being considered, the sole considerations of value which here form the diagnosis reside in this : 1st, the condition of the glands ; 2nd, concomitant manifestations ; 3rd, ulterior evolution.

1. *State of the Glands.*—This is an excellent symptom in general, but only in general, and not absolutely or constantly.

With the syphilitic chancre, in fact, there is constant affection of the glands, which is never wanting. M. Ricord has been able to say with reason, "the bubo is the faithful companion of the syphilitic chancre ; it is its forced satellite." Besides, with the chancre the affection of the glands is well marked, with the characters which I have so many times pointed to and placed under the finger, *i. e.*, multiple glandular affection, forming true pleiads, hard affection of the glands, indolent, and often also in both inguinal regions, affecting equally or unequally both sides.

(To be continued.)

## CLINICAL MEMORANDA.

Reported by JOHN W. MARTIN, M.D.,

Assistant-Surgeon Mayfield Factory Dispensary, Portlaw, &amp;c., &amp;c.

THE following brief notes of a case in which complete amaurosis of the right eye accompanied fracture of the nasal portion of the superior maxilla, together with the palate, and most probably the lachrymal bones, will, I think, prove interesting and be worth placing on record.

Michael Wall, æt. 60, a labourer, in the course of a dispute with his son-in-law, received a blow from a stone, which inflicted a severe lacerated wound, involving the upper eyelid on the right side and the bridge of the nose, also the fractures already enumerated.

On the 24th of February, 1874, the wound being nearly healed, he presented himself, complaining of severe pain in the orbit and temple, right side, complete loss of sight and lachrymation, the tears escaping over the cheek. There were no symptoms of external inflammation. The inner canthus of the eye was displaced downwards and outwards. Examination with the ophthalmoscope revealed well-marked congestion of the retina as compared with that of the unaffected eye. Motions of both eyes normal. Bowels acting. General health good.

R. Solution hyd. bichloridi, ʒi. ;  
(Strength, gr. i. to ʒi.)  
Tr. aurantii ad ʒij. M.

One teaspoonful to be taken three times a day in a little water, after meals.

Applied strong tinct. of iodine to the temple.

Friday, 26th.—Headache diminished; sight returning; objects seen indistinctly; when looking straight before him is unable to see anything placed above the level of his eye. Retinal congestion diminished.

February 28th.—Range of vision increased; objects seen more distinctly. Lachrymation and headache diminished.

March 4th.—Treatment altered to biniodide of mercury in mixture. Improving.

March 12th.—Ordered mist. potass. iodidi c. cinchona. Subsequent history one of steady improvement and recovery of sight.

The points of interests are the complete amaurosis dependent on retinal congestion and the rapid and steady improvement when placed under mercurial treatment.

## INDIAN MEDICAL NOTES.—No. XXV.

(FROM OUR SPECIAL CORRESPONDENT.)

SIMLA, August, 1874.

## A POETICAL EXTRACT.

RECENTLY, at lunch, meeting Colonel Gordon and Dr. Bellew, just returned from Yarkund, they mentioned that the cold was twenty-six degrees below zero at 18,500 feet, when bed-clothes were welded together by frozen perspiration, which the heat of the body would not thaw, and as ink and colours solidified, their notes and sketches had to be pencilled. Excepting the accomplished naturalist, Dr. Stolicza, who died of symptoms allied to those of sun-stroke, depending on cold and rarefaction of the air, all during the year enjoyed excellent health, whilst living on sheep, green tea, occasionally horse-flesh, very little liquor or tobacco being expended. Last night, after dinner, it was necessary to visit a case of infantile remittent fever, far down in a valley, just as you would descend from a lofty cliff to the beach below, the dark zig-zag paths leading

occasionally past native habitations. Oh, the smell—enough to knock down the most hardened medical officer of health. Imagine a slice of Bethnal Green or Seven Dials, between any two points—say between Kemp Town and the Grand Hotel at Brighton: even then no idea can be formed of the bazaar at Simla in the centre of the Mall, the two ends occupied at intervals by residences, now and then a shop exorbitant. There are houses on the ledges above, as well as on various ranges, steppes, or plateaux in the valleys below; those above have a mixture of good air and clouds, and are surrounded by lofty firs and graceful cedars, the peerless deodar, the glory of the Himalayas, the tree rhododendra, covered with rare ferns or feathery mosses, while, it stands to reason, others in the ravines below must put up with torrents, waterfalls, miscellaneous drainage and drinking water flowing sociably down together to the valleys. The geological formation consists of metamorphic rocks, indurated clay, slate, grit, conglomerate, limestone, siliceous schists, mica, garnet, quartz, and either china clay or hydrated silicate of alumina, some say meerschaum. The station ranges from 5,000 to 8,000 feet above the level of the sea, about 56 miles from the plains by the new road, whose gradient of three feet in a hundred permits driving: Meerut to Umballa, by rail, 124 miles; next to Kalka, the foot of the mountains, 38 miles by road; the remainder of the journey by the old road—41 miles—can be walked, or ridden, or carried over by ambulance bearers, your luggage conveyed also by hand. Most persons prefer the driving on the other road, but for a man with liver, a lady advanced in pregnancy, or a three-months' infant all but moribund (my travelling companion) the old road is suggested, taking it easy, halting at appointed stages, one, for instance, near the Laurence Asylum for soldiers' children, concerning which, more anon. Under any circumstances, the journey is very trying to the congested liver or the displaced gravid uterus. The drive from Kalka to Simla, by relays of ponies, occupies hours, and costs twenty-four shillings; the scenery, fruits, flowers, vegetation, have been alluded to previously, the honeysuckle, and the wild red pomegranate specially attractive. There are 300 European houses, chiefly of wood, with shingle roofs, ranging from 400 to 3,000 rupees for the year, to accommodate 1,400 Europeans; the native population, 13,000, housed in their own fashion; the station occupied not fifty years. The rainfall ranges between 50 and 70 inches, and, according to the interesting guide, to stray Blue-books, to short papers by Drs. Paske and Ross, to personal inquiries and observations, the other points are as follows. I was going to visit the sulphur lake of Nyna Tal, but the sick family of a kind friend required urgent medical attendance to Simla—*Veni, Vidi, Vici*—so far as tinkering up the patients, the hill women, who drink water, being splendid wet-nurses. Bring plenty of money, the best of clothes, uniform, dancing pumps, wraps and waterproofs, stay at Harding's Hotel at £10 a week, call, after inquiry, on the best and the nicest people, who one and all extend unbounded hospitality, and what with Badminton, lunches, dinners, riding parties, pic-nics, occasional dances, the time will fly. The medical officer may also have patients to visit—anxious cases mine at present are—and you may be called into consultation, enlisted by a fee. The great thing is to make friends who may eventually assist the sole object of life in India—a billet in the Hills. The plains have been already described. Contrast the temperature of Simla for each month of the year: January 40, February 44, March 53, April 61, May 66, June 80, July 75, August 73, September 70, October 67, November 52, December 46. March and May are stormy months; May and June dry; then rains until September, followed by glorious crisp, bracing weather, when the exhilarating air is sharp and clear, when the snowy range appears (22,000 feet), and the hills of blue and green are relieved by wild geraniums, anemones, primroses, violets of various hues and shades Napoleonic—in fact, it sets one crazy to talk of these things. Trees are my favourites, and as in the agonies of

composition the eye in a fine frenzy rolls, the deodara cedars outside and the cool splash of the waterfalls drive medicine out of mind this glorious August morning.

Dr. Ogilvy, Secretary to the Burra Lord Doctor Sahib (as the surgeon-general is termed), has some wonderful vegetables, besides brilliant sweet-scented flowers. "Nothing like hunting," said Mr. Jorrocks; "Nothing like gardening for pleasure, peace of mind, and recreation," replies many a doctor besides Smee. The water, originally pure, starts from twenty-seven springs, eighteen permanent, some on a lower level than many houses, some in water-courses, others bubbling or trickling out of the sides of the lofty rocks, flow over organic refuse, stable manure, ordure, filth about houses, carcasses of animals, and thus down the valleys the drainage and water-supply socially mingle. At one time it was said that 4,000 natives used nooks and dells for latrines, and even now, when matters are improved to the utmost of practicable endeavour, the habits of the water-carriers are by no means immaculate. Widening roads, flushing drains, building ventilating shafts, repairing rotten, damp, tumble-down habitations, enforcing conservancy, regulating the butchers and their slaughter-houses, the authorities are not idle. The old grievances were crowding of trees, and of native hovels, indifferent drains of wood, or lime on slopes through spongy soils, damp houses built against banks, indifferent bedrooms, dark, damp, badly floored, and mostly situated on the side of the bank, noxious smells, dirty servants' houses, unchecked deciduous vegetation, bad meat. According to Paske, the sheep, fed on offal, were killed and dressed near drains; the bread, made in hovels, was mixed with spices and honey instead of obtainable yeast, and a Mahomedan burial-ground in a clay soil had a drinking-tank at some distance below. In the plains a dead animal soon dries up; in the hills the decomposition is slow. In 1867 the 67 Government clerks, with families of 103, had an average sick list of 8 per cent. from April to September, especially during the rains, when malarious mists are trying; formerly, too, the want of sanitation induced diarrhoea, dysentery, scurvy.

This very morning have I been prescribing for Simla trots, a painless, prolonged, ochrey diarrhoea, remedied by podophyllin, followed by acids or pernitrate of iron; if neglected the patient may have hepatic complications, or a chill just now will induce pneumonia, or infantile remittent, complicated with bronchitis. For the last five nights it has been my luck to watch two dangerous critical cases, and as the damp rhododendron wood refused to burn, preferring to smoke out the sick-room, and the doors had to be closed against the rain and the damp mists which permeate the poorly-cemented walls, the many nights spent at sick-beds of humble and well-to-do folks elsewhere crowded reflections. Rheumatism, neuralgia, and hepatic ailments affect specially the careless, who sit up late at night, eating or drinking incautiously, or who go in for violent exercise too soon on arrival. Cases of advanced syphilis, or phthisis, of organic cardiac mischief, or progressive hepatic disease, in old subjects, sometimes do well—more frequently lose ground; still, every case must be taken on its own merits, for the curative action of the Himalayas is unbounded—something passing conception. Ascending from the plains may induce intestinal chills; the descent from hills to plains brings back fever, deafness, abdominal cramp. The gay Lotharios who may admire the handsome Cashmere Cyprians, with raven tresses, coal black-eyes, fair faces, supple busts, and attractive limbs, ornamented with silks of green and gold and gaudy tinsel, should remember that the C. D. Acts are not in force, and that syphilis in Protean shapes is ever rife. Goutre very prevalent. A volume might be written about Simla, indeed, ought to be, considering it is the Brighton of India; but, really, the civil surgeons and others have nothing to go upon, as they are only here two years—like the needy knife-grinder, they have no story to tell; no statistics, no neat, terse, topographical account can as yet be met with. Printed analyses of water are of very little assistance. There are novels and sketches, the same old weary tale of dissipation, flirta-

tion and folly, of racketty invalids, loafers, impostors, schemers, gamblers in former times, and many a story ending in sorrow, ruin, and shame. It is a delicate, dangerous subject to touch upon. Every man of the world knows that in England a great deal more goes on than people talk about; but here a new bonnet, your means, character, and food for dinner are well known, and husbands ill, absent, or negligent, may often have to blame themselves if their pretty wives are pestered with attentions by idle bachelors. If you ride with Mrs. Jones, or dance frequently with Miss Brown, most innocently, look out for tattle. But, really, the exciting air of the hills prompts many people sometimes to lose their heads and make fools of themselves—a kind of disease not included in the nomenclature of the College of Physicians. As said before, the fair sex have a deal of suffering or anxiety about their children—suffer from leucorrhœa, menorrhagia, chlorosis, uterine displacement, and diseases no fault of their own, very difficult, indeed, at times impossible, to relieve, until at last they give up all hope of improvement, and, sick of doctors, they conceal their pain. The voyage home alone may effect a cure, claimed by the London specialist. Out of the *Pioneer* is the enclosed clever poetry extracted; I hope it will not be considered unsuitable for insertion at this stage of the "Notes." As Toole, the inimitable, after a dreadful pun, used to say, this really shall not occur again.

#### THE WORSE LAND.

I hear thee speak of a place in the Hills,  
Where scandal or gossip each moment fills;  
Father, O! where is that heavenly place  
Where women go at a terrible pace?  
Is it where the teeming tea-plant grows,  
Where sleeps Darjeeling beneath the snows?  
Not there—not there—my child.

Is it where the feathery deodars rise  
Like Fairy giants 'neath Simla skies?  
Where green young griffs in glittering lace  
In the hearts of the fair may find a place?  
Where strange, bright, foolish, frivolous things  
Have waists like wasps—but with double stings?  
Not there—not there—my child.

Is it far away in Mussoorie old;  
Whence many a shocking tale is told,  
Where garish beauty and tinsel shine  
Like diamonds fresh from the secret mine—  
Where pearls and rubies and riches grand  
Weld all together the motley band?  
Not there—not there—my child.

Thine eyes dare not see it, my gentle girl,  
Thine ears must not bear its incessant whirl,  
Dreams cannot picture its orgies wild,  
Parties on Sunday nights—my child,  
Time shall yet for an answer call,  
From the cloudy regions of Nynee Tal,  
For—'tis there—'tis there—my child.

## Hospital Reports.

### THE WESTMEATH INFIRMARY.

#### Successful Operation for Strangulated Inguinal Hernia.

RICHARD D—, a labourer, æt. 54, was admitted into the Westmeath Infirmary, suffering from strangulated inguinal hernia of right side, on June 16th, 1874.

He had been suffering from this hernia for some years, not knowing what it was, and the dangers attached to it, as well as from its never having troubled him, he neglected having medical advice. On Saturday, the 13th of June, he was cutting turf in the bog. During his work he found it "beginning to hurt him;" he then put down his hand and found the "lump" had become larger. He did not pay any attention to it, but went on with his

work, the "hurting" still continuing. He got no relief during the night, and the next day vomiting set in. He did not send for a doctor, that day "being Sunday." On the following morning his wife procured a dispensary ticket, and the district medical man having failed in his endeavours to reduce it, and seeing the dangers of the case, sent for the assistance of another medical man. They, after consultation, came to the conclusion that the only means to save his life would be by operation. Owing to the position of the man in life, and the consequent want of the means for the success of such an operation, they had him at once removed into the hospital, where I met him on his arrival. He was then suffering some pain, still vomiting, nothing passing from the bowels, the tumour about the size of a large apple, and very tense, pulse 90, tongue only slightly furred, countenance natural. Seeing there was no necessity for immediate operation, I resolved to try every other means first. He was put into the warm bath, taxis in every form used, and finally he was put under chloroform. All failed. It being then late at night, and there being no symptom of immediate danger, it was resolved to leave him till next morning, when, under the guidance of a consultation, the operation of opening the sac was performed in the usual way. The man refusing to take any more chloroform after the night before, the operation was performed without its aid. On the sac being opened, it was found to consist of intestine only, with a good deal of effusion. The intestine was a good deal congested. On passing the finger into the ring, the stricture was found at the inner edge of the external ring. This required a very free division before the bowel could be returned. The wound was then brought together with silver wire sutures, and dressed with a pad of lint wet in cold water, and securely bandaged. He was put to bed and kept in the recumbent posture, with the legs well flexed; an opiate given. On the fourth day the bowels were opened with a little castor-oil. The wound was daily dressed with a pad of clean lint. All went on well, and he was discharged cured on July 25th, previously having a truss fitted to him.

## STUDENTS' COLUMN.

### LESSONS ON PRESCRIPTIONS AND THE ART OF PRESCRIBING. (a)

By W. HANDSEL GRIFFITHS, Ph.D., L.R.C.P.E.,

Licentiate of the Royal College of Surgeons of Edinburgh, Honorary Member of the Ontario College of Pharmacy, Librarian to the Royal College of Surgeons in Ireland.

#### LESSON VI

##### INCOMPATIBILITY.

SUBSTANCES are said to be incompatible when their combination gives rise to chemical changes, a new compound being formed which is either inert or possessed of distinct properties. Chemical incompatibility, however, does not always signify therapeutical inertness. Substances which are chemically incompatible are sometimes intentionally combined in order to obtain a new compound; as, for instance, in the official *mistura ferri composita* a decomposition occurs between the sulphate of iron and carbonate of potash.

The subject of incompatibility is, as Parrish says, "too much of a stumbling block to the student." The older text-books of materia medica contained a long list of so-called incompatibles, which the unfortunate student was expected to commit to his already over-burdened memory. It is now known that many of these "incompatibles" are not incompatible at all, and that many of them might be excluded from the list, from the extreme unlikelihood of anyone ever prescribing them together.

Incompatibility may be threefold, viz. :—

1. Chemical.
2. Pharmaceutical.
3. Physiological and therapeutical.

We have given above the signification of *chemical* incompatibility. By *pharmaceutical* incompatibility we mean combination of such substances as are physically incapable of mixing; thus, if nitrous ether be added to tincture of guaiacum a gelatinous mass will result, or if resinous tinctures be added to aqueous solutions the resins will separate. The following are some of the more striking examples of pharmaceutical incompatibles, and they should be carefully remembered by the prescriber :—  
Compound infusion of cinchona with compound infusion of gentian.

Infusions generally with metallic salts.

Tinctures made with strong alcohol, with those made with weak alcohol, and with infusions and aqueous liquids.

Essential oils with aqueous liquids exceeding one drop to f. 3j.

Fixed oils and copaiba with aqueous liquids, except with excipients.

In our last lesson we alluded to the subject of *physiological* or *therapeutical* incompatibility. By this term we imply combination of such substances as possess opposite therapeutical and physiological properties, and which are medicinally inconsistent; for instance, belladonna would be physiologically incompatible with calabar bean.

I will now ask your attention to the following simple rules, a knowledge of which will be sufficient to guard you from the commission of any flagrant errors in the matter of chemical incompatibility.

#### LAWS OF CHEMICAL INCOMPATIBILITY.

1. Two salts in solution may form, by the interchange of their acids and bases, two insoluble salts which are precipitated.

2. When two salts in solution form, by the interchange of their acids and bases, a soluble and an insoluble salt, the latter will generally be precipitated, or may form with the soluble salt a double salt.

I have before me two clear solutions, one of chloride of barium, the other of sulphate of soda. As I mix them you observe the formation of a copious precipitate; this is insoluble sulphate of barium. If we now filter off the clear fluid, we will find it to be a solution of chloride of sodium.

3. When two salts in solution do not give rise to an insoluble salt no precipitate will result, though there may be decomposition.

4. An acid will decompose a salt—

(a) If the acid added be more fixed or more soluble than that of the salt.

(b) If the acid added can form an insoluble or a less soluble compound with the base of the salt.

(c) If the acid added possess a greater affinity for the base of the salt.

(d) If the acid of the salt be gaseous.

I have in one vessel dilute sulphuric acid, and in another vessel I have some liquor ammoniæ acetatis. You observe that, as I mix them, acetic acid is given off, and the fluid on examination will prove to contain sulphate of ammonia.

5. Oxides of the alkalies decompose salts of the metals proper and of the alkaloids, and precipitate their bases, or the base may be soluble in excess of the alkali.

Here is a solution of sulphate of zinc; as I add to it a little liquor potassæ, you see the formation of a precipitate of oxide of zinc; as I add more of the liquor potassæ, the precipitate becomes dissolved.

6. Metallic oxides combine with acids to form salts.

7. Vegetable substances containing tannic or gallic acids precipitate albumen, vegetable alkaloids, and most of the metallic oxides, and form with salts of iron inky solutions. Substances containing tannic acid also precipitate gelatine.

8. Glucosides are incompatible with free acids or emulsions.

(a) Corrected from shorthand notes by one of the author's pupils.

As a general rule the following substances should be prescribed alone, and are best given in simple solution :—

Acid. hydrocyanic. dil.	Potassii bromid.
Acid. nitro-hydroc. dil.	Potassii iodid.
Antim. tart.	Potassæ permanganas
Liq. calcis	Potassæ acetat.
Liq. potassæ	Zinci acetat.
Liq. potassæ arseniat.	Morphiæ acetat.
Liq. ferri pernit.	Morphiæ hydroch.
Tinct. ferri perchlor.	Quiniæ sulphat.
Tinct. iodi.	

I now propose to pass in review some of the more important instances of individual incompatibility, but in this survey I shall generally omit instances bearing on the rules we have above enunciated.

**ACID. HYDROCYANIC. DIL.**—This is not unfrequently prescribed with alkalies; a cyanide of the metal is thus formed, which is not less active than the acid itself.

**ACID. PHOSPH. DIL.** may be prescribed with syrup of phosphate of iron; if, however, it be combined with syrup of pyrophosphate of iron, the mixture becomes solid.

**ACID. SULPH. DIL.**—The rules which I have above given will obviate the necessity of enumerating the long list of substances with which this acid is incompatible. There is one combination, however, which I must warn you to avoid. Sulphuric acid is, as you are aware, very efficacious in cases of internal hæmorrhage, and so are the lead salts; we may not, however, combine these agents, as an insoluble sulphate of lead would result.

**ACID. NITRIC. DIL.**—Dr. Paris writes that he has seen a formula in which "a tincture of opium was directed to be prepared with rectified spirit, and mixed with undiluted nitric acid! In this case it may very safely be inferred that its author was not only ignorant of the chemical habitudes of those bodies, but that he was moreover guiltless of ever having perpetrated the act in question, or he would undoubtedly have found that, in consequence of the mutual action of these ingredients, *hyponitrous ether* is rapidly produced, and it is probable that the phial and its corrosive contents would have exploded, to the imminent hazard of the operator's eyes."

**ACID. TANNIC.** may be prescribed with the protosalts of iron, but not with the persalts. Galls and tannic and gallic acids are said to be incompatible with infusions and decoctions containing alkaloids, but tannates of alkaloids are by no means inert; tannate of morphia will induce sleep, and tannate of emetine will cause vomiting. Tannic acid is also incompatible with gelatine, and with many metallic substances.

**ACID. TARTARIC.**—This acid was formerly much used in making saline draughts. Now, if bicarbonate of potash be added to a solution of tartaric acid, titartrate of potash is thus formed, and at once precipitated; but if the tartaric acid be added to the salt of potash, no such untoward circumstance will occur.

**ALUM** is incompatible with alkalies and their carbonates, with tannic acid and preparations containing it, with tartrates, salts of lead, lime, and baryta, &c.

**ANTIM. TART.**—Acids, alkalies and their carbonates, and some earthy and metallic preparations cause precipitates with tartar emetic, but these precipitates are soluble in excess of caustic alkalies. If tartar emetic be combined with astringent vegetable infusions an insoluble tannate of antimony will result. I may here mention that tartar emetic is often, and with perfect propriety, prescribed with sulphate of magnesia.

**ARGENTI NITRAS.**—It is almost unnecessary for me to remind you that this salt should not be dissolved in undistilled water or in vegetable infusions.

**ARGENTI OXIDUM.**—This substance is incompatible with many organic substances. On account of its influence on the mucous membrane of the stomach, it might possibly occur to a practitioner that it would be a valuable addition to creasote in certain cases of vomiting. The result of such a combination would be spontaneous combustion.

**FERRI ET AMMONIÆ CITRATIS.**—This salt is sometimes prescribed in effervescence. In such a case the iron salt must be put into the citric acid solution, and not into that of the bicarbonate of potash; if the latter course be adopted, carbonic acid would be given off, with the probable effect of bursting the bottle. This salt is often prescribed with tincture of orange alone; it will be well to remember that unless *some* water be added, it will be insoluble in this menstruum.

**FERRUM TARTARATUM** may be prescribed with alkaline carbonates.

**HYDRARGYRI PERCHLORIDUM** is incompatible with vegetable preparations containing albumen or tannin. It is precipitated by alkalies, alkaline sulphurets, iodides, tartar emetic, &c.; in fact there is hardly anything with which it is advisable to combine corrosive sublimate except chloride of ammonium, which increases its solubility, and decoction of sarsaparilla.

**HYDRARGYRI SUBCHLORIDUM.**—You should be very careful not to order calomel in combination with any preparation containing a trace of prussic acid. Innocuous as calomel itself is, comparatively speaking, it is converted by prussic acid into bichloride and bycyanide of mercury, two virulent poisons.

**MAGNESIA SULPHAS.**—I have seen a prescription in which Epsom salts was ordered with calcined magnesia and colchicum wine; the result of such a combination would be an insoluble bulky mass.

**PLUMBI ACETAS** is incompatible with nearly everything except solid opium and distilled water. If common water be added to liquor plumbi subacetatis, carbonate and sulphate of lead will be thrown down.

**POTASSII IODIDUM.**—Should not be prescribed with sweet spirits of nitre, acid preparations, or those containing starch. In fact, iodine and iodides should be prescribed with as few additions as possible. Iodide of potassium decomposes nearly all metallic salts.

**CALUMBA.**—When we desire to combine salts of iron with a vegetable tonic, calumba may be chosen, as it contains no tannic or gallic acid.

**CAMPHORA** forms soft masses with gum resins. It destroys the odour of musk.

**CARTOPHYLLUM.**—Cloves contain tannin, and hence should not be prescribed with iron salts.

**TINCT. CASCARILLÆ.**—This preparation is not unfrequently prescribed with dilute mineral acids; the combination is however objectionable, as floccules soon float through the mixture. If it is desirable to combine an acid with cascarrilla, the infusion of that drug should be selected.

**TINCT. CANNABIS INDICÆ.**—If this or other spirituous solutions of resinous substances be added to water, the resin will be precipitated, unless mucilage be added in order to suspend it.

**TINCT. GUAIACI.**—I have already alluded to the fact that the addition of nitric ether to this preparation causes the formation of an unsightly bluish-green mass.

**CHLOROFORM** will not remain mixed with weak spirits or with glycerine.

**BELLADONNA, HYOSCYAMUS, and STRAMONIUM.**—It has long been known that caustic fixed alkalies decompose the alkaloids of these agents. Runge demonstrated the fact long ago, although a very recent author must have been ignorant of this, for he writes as if he claimed the discovery for himself. Carbonates and bicarbonates of the alkalies may be prescribed with preparations of these drugs.

**OPIMUM.**—The older text-books contained a long list of substances which were supposed to be incompatible with opium, most of these are not now considered as improper combinations. Tincture of opium is not unfrequently prescribed with acetate of lead; a decomposition takes place resulting in the formation of acetate of morphia and insoluble meconate of lead.

**QUINÆ SULPHAS** is often prescribed in combination with infusion of roses, and a turbid and unsightly mixture results.

I will conclude the subject of incompatibility by reminding you that we are not always to infer, that because a substance is insoluble in water, it is necessarily therapeutically inactive. Such substances may oftentimes be so operated upon in the laboratory of the human economy as to become essentially active and potent.

WEDNESDAY, SEPTEMBER 23, 1874.

### PROPOSED RECONSTRUCTION OF THE ARMY MEDICAL DEPARTMENT.

WE have been favoured by a correspondent with advanced proofs of an article which, we presume, has since appeared in an Indian military contemporary, upon the condition of the Army Medical Service, and as it deals fairly not only with the just complaints of the army medical officers, but with the necessities of the military service in respect to its medical organisation, it appears to us well deserving of perusal.

The altered system of war, says the author, has naturally necessitated a reconstruction of the Army in all branches, but in none was this more imperative than in the medical department.

There were more men wounded in a single day during the Franco-Prussian war than in a year of Peninsular campaign, and still our Army Medical Department is not better organised now than it was twenty years ago; in no way has it kept pace with the rapid advances made by other branches of the service.

It has therefore become a matter of pressing necessity that the best possible scheme of hospital organisation be at once devised and adopted. The importance of such a service cannot be overrated; not only an incalculable amount of health and life, but the very existence of an army may depend on it. At the Alma, had there been an efficient hospital corps capable of taking complete charge of the wounded in the field, Lord Raglan could have followed up his victory at once and taken Sevastopol, by which the suffering, life, and treasure thrown away during the following twelve months would have been saved.

The department has never been what the public had a right to expect. Its maladministration in the great hospitals in the Peninsular is a matter of history. In the Crimea things were nearly as bad; hospitals that should have been models of hygienic combinations were pest-

houses, and doctors were powerless for good. Its failings were never brought very prominently before the nation; not indeed until Dr. Russell's celebrated letters appeared in the *Times*, did they attract special attention. Since then no improvement or progress has been attempted by any Government; on the contrary, many of the reforms introduced by Lord Herbert have been abrogated from time to time, and were we to engage in war now, our last state would be worse than the first. Who is to blame for this? Apparently no one! The responsibility divided amongst so many, is insensibly lost, and will neither be accepted in the War Office, the Horse Guards, nor in Whitehall Yard.

In other days, when war dragged lazily along, perhaps lasting many years, with a battle now and then, slow marching, winter quarters, &c., an army sent its bad cases only to the general hospitals in the rear, and carried most of its sick and slightly wounded with it. These did very well, except perhaps in a retreat or during hurried movements, when of course they came more or less to grief. This was the regimental hospital system, and was carried out under the orders of the commanding officer by a surgeon and two or three assistant-surgeons, integral parts of, and belonging to, the regiment. It did not answer very well in war, but in peace it exhibited the most perfect organisation for the comfort of the sick that perhaps has ever been attained.

Even medical officers most wedded to the regimental system confess that the latter must be abandoned in war, and they admit the necessity for a sanitary corps, in which interest in, reliance on, and knowledge of, each other by officers and men, would ensure an efficient, useful, and well-disciplined body.

The organisation and development of such a corps appears beset with difficulties. In the first place the removal of medical officers from their regiments is very unpopular with all combatant ranks. The commanding officer likes to have his sick under his immediate eye, he is proud of his hospital, he shares with his doctor in the compliments almost universally paid it by general officers.

The doctors are equally opposed to the general staff system, or to what is erroneously called "Unification," and it is not to be wondered at if their case be fairly represented from this point of view as well as from their own.

It is said that the Royal Medical Warrant of 1858 has been violated from time to time during late years till scarcely any of the privileges conferred by it remain. Medical officers felt much aggrieved by these numerous breaches of faith, and for some years a deep feeling of dissatisfaction has existed equally prejudicial to the service, to the officers, and to their progress and professional advancement. This condition of things did not manifest itself prominently, owing to the majority of the officers concerned being isolated and contented in their respective regiments.

Suddenly, on the 1st March, 1873, a new warrant appeared, summarily removing medical officers from their regiments and placing them on a general staff list. The effect of this was, that their old and formed friendships and associations were broken up, they lost their

homes, and the advantages of mess, library, bands, &c., in which they had established vested interests; many lost large sums paid for exchanges, varying from £100 to £1,000. The loss occasioned by change of uniform and appointments, and by the forced sale of horses was considerable. The loss in servants may be estimated at £30 per annum where one was allowed, and to £60 to officers entitled to two, as a servant cannot be maintained for less than £50 per year, whereas the Government allowance is £18 5s. From being members of distinguished corps and regiments they found themselves placed in a medical staff corps without prestige, position, or standing, and liable to be sent to any part of the world at a few days' notice. Besides this, much additional work was imposed on them in having to take over duties hitherto performed by purveyors and storekeepers, whose offices were now abolished, while at the same time, the strength of the department was reduced from over 1,000 to less than 900 officers, by which means a saving to the Government of over £20,000 a year was effected, at the sole expense of the medical officers.

As it is a matter of importance that every branch of the Service should have no just ground of grievance or discontent, it will be naturally asked, what recompense did the wise War Minister offer the department in return for the losses and extra work he imposed? He allowed assistant-surgeons to call themselves surgeons, and surgeons to be styled surgeons-major, while deputy inspectors-general became deputy surgeons-general, and inspectors-general surgeons-general, and that is all!

The following basis of the proposed reorganisation of the medical department appears to obtain general approval; it has great advantages, even from Mr. Cardwell's point of view, for while it would cost the country nothing, it would restore to medical officers most of the regimental advantages they have lost, and give to the authorities economy and the unification necessary to the reconstruction of the department.

I. The Army Medical and the Army Hospital Corps to be amalgamated into a Royal Sanitary Corps, taking rank with the other scientific corps.

II. That the officers of the Royal Sanitary Corps shall rank as follows:—

Surgeon-general as major-general.

Deputy surgeon-general as colonel.

Surgeon-major (over 20 years) as lieutenant-colonel.

Do. (under 20 years) as major.

Surgeon (6 years' service) as captain.

Do., on appointment, as lieutenant of four years' service.

III. That the officers of the Sanitary Corps be permitted to wear the ordinary distinctions and badges of such rank on their uniforms, with such others as may be special to the corps, it being distinctly understood that the privileges give them no command whatever, except over patients in hospital or officers and men immediately attached to hospital establishments.

IV. That the Corps be divided into some thirty divisions under deputy surgeons-general, to move on home and foreign service like brigades of artillery. Only officers to proceed to India. This scheme would give one year's foreign service.

That medical officers be completely separated from

regiments. When doing duty with them to be attached as honorary members only; that they pay mess and library subscriptions to their departmental institutions, and live in their own messes whenever practicable.

V. That for all duty purposes medical officers be kept with corps as long as possible.

Under the divisional system suggested in No IV., medical officers could remain with regiments quite as long as they did formerly, viz., three years on an average.

It would be seldom necessary to remove them from their corps in Gibraltar, Malta, West Indies, The Cape, Ceylon, &c.

They should accompany the regiments when they moved to new stations, and after handing them over there to medical officers having some experience of the—perhaps to the regiment—new country, return to their original stations.

For India this organisation would be simpler still.

VI. That, except for duty, medical officers be completely separated from regiments, that they live in their own messes whenever practicable, and pay mess, library, &c., contributions to their departmental institutions, which might be formed on the model of the station messes of the Royal Artillery.

When, however, their own messes might not be available, and they became honorary dining members of other messes, the latter to be entitled to the subscriptions.

VII. That the sick continue to be treated regimentally until experience shows the way to that system which may prove most suited to peace and to meet the exigencies of war.

The medical officers deserve sympathy for the weary worry they have suffered through short-sighted policy. Honour points out the way by which they can best benefit their country, and although it is opposed to their interests in many instances, there is no doubt as to the course they will adopt, for self sacrifice has never been asked in vain from the members of their glorious profession. They have every assurance of the great sorrow felt by the officers, non-commissioned officers, men, women, and children at their removal from amongst them. For hundreds of years they have been the persistent champions of the soldier, and his companion through danger, pestilence, and battle. Their literary productions, records, and the acknowledgments by Royalty, Lords and Commons, of the obligations the country and army have been under to them, abundantly testify to the weight and brilliancy of their services. They have gained, against powerful opposition in high quarters, those great sanitary improvements which have added, it is calculated, at least five years to the average duration of the soldier's life. They have nearly succeeded in eradicating scurvy, consumption, dysentery, and typhus, that—half a century ago—were scourges of the army, and in themselves produced a higher death-rate than now occurs from all causes. We hope the victory over other dread diseases may soon follow. There is the study of divine thought and loving kindness in Nature, following humbly in the footsteps of the Great Physician and Healer; there is the greatest work the mind and intellect of man can be applied to, and the most highly honoured since all time. Therefore, we say, medical officers need not fear loss of prestige or position in being embodied in a military

medical corps which may trace its descent from the Knights of St. John and the Templars; the first corporation who devoted themselves to the care of the sick and wounded in war, and who had to arm themselves and fight in defence of their charge.

### THE PUBLIC HEALTH (IRELAND) ACT.

THE first step towards carrying this important enactment into effect has been taken within the last week by the Irish Local Government Board. They have issued to the various sanitary authorities, rural and urban, their sealed orders to proceed at once to the appointment of officers.

The total number of sanitary authorities constituted by the Act is 205, of whom 163 are boards of guardians and 38 are governing bodies acting as urban authorities—in other words, township commissioners—the remaining 4 being the Corporations of Dublin, Cork, Belfast, and Limerick.

The "Public Health (Ireland) Act, 1874," as the Local Government Boards points out, contains many important amendments of, and additions to, the previously existing sanitary laws, but the bulk of the enactments relating to water-supply, sewerage, the removal of nuisance, and remedies of other matters dangerous to public health, are found in the Sanitary Acts of previous date to 1874, having been administered by boards of guardians and governing bodies both before and since the passing of the Sanitary Act, 1866.

The Board, in their circular note, point out that the principal functions of sanitary authorities will be to ensure the purity of the air and water of their districts, and they conclude with an expression of the hope that the sanitary authorities newly constituted may, by a moderate and persevering, but not oppressive, use of their powers, be able to make improvement universal within a reasonable space of time, and by means of a moderate amount of expenditure.

The "sanitary orders" which accompany this circular are addressed to the various sanitary authorities, and require them to hold their first meeting in such capacity on the day of the second weekly meeting of the Board of Guardians after the receipt of the order. They are reminded that "by the tenth section of the said Act, every medical officer of a dispensary district shall be a sanitary officer for such district, or for such part thereof as he shall personally be in charge of," and they are required to proceed, as soon as may be, to appoint—

1. Sanitary sub-officers (as many as may be necessary). For this office "the relieving officers of the union and the collectors of poor rates shall be alike eligible."

2. One consulting sanitary officer, for which office "every medical officer of the union, including the workhouse medical officer or officers, shall be eligible, and also subject to our approval, any other medical practitioner having the same qualifications."

3. One executive sanitary officer, for which office the clerk of the union, or any assistant of the clerk appointed by the guardians, shall be eligible.

The duties of these officers are thus defined:

#### I. INSPECTORIAL DUTIES.

1. Every sanitary sub-officer who shall observe, or be

informed of any matter demanding, in his opinion, attention from the sanitary officer of the dispensary district in which he has discovered the same, shall notify it forthwith to the sanitary officer in writing, specifying the nature of the case in the Form (a) in the Schedule B to this Order annexed, and shall preserve a copy thereof in duplicate.

2. Every sanitary officer who shall have been apprized officially, or shall otherwise become cognisant of any matter demanding his attention as aforesaid, shall, as soon as conveniently may be, visit the locality, and if, after due inspection, he finds such matter to involve danger to public health, he shall report thereon to the Board of Guardians, in the Form (b) in the said Schedule B, showing the source from which he received the information, and the date thereof, and the date of his visit of inspection: he shall also give a sufficient description of the nature of the case, and the remedy which he recommends to be adopted, and shall preserve a duplicate of every such report.

#### II. EXECUTIVE DUTIES.

1. The duty of the executive sanitary officer shall be to attend every meeting of the guardians acting as a sanitary authority, and to take their directions from time to time on the sanitary business of the Board, and on the reports of the sanitary officers, and all proceedings arising therefrom, and to see that the same are carried out and brought to a conclusion where practicable, in pursuance of the orders of the Board.

2. In furtherance whereof we do hereby direct that every sanitary officer and sub-officer of the union shall, on receiving directions from the executive sanitary officer, attend and assist in all proceedings in which his attendance or assistance may be deemed necessary.

3. The duty of the consulting sanitary officer shall be to attend meetings of the guardians acting as sanitary authority, whenever required to do so, and to advise them on all matters and proceedings requiring medical knowledge and advice in the administration of the sanitary laws.

4. The proceedings of the Board of Guardians acting as the sanitary authority shall be recorded in the same manner as the minutes of the proceedings of the Board under the Poor-law and Medical Charities Acts, and a copy of such record shall be annexed to the ordinary minutes of proceedings of the Board of Guardians, and shall be transmitted to the Local Government Board by the clerk of the union with such last-mentioned minutes.

#### III. STATISTICS OF DISEASE.

It shall be the duty of the consulting sanitary officer and of the sanitary officers to furnish from time to time to the Local Government Board such statistical returns of sickness and disease in the workhouse and its hospitals, and in the dispensary districts, as shall from time to time be required from them respectively.

### THE DOCTOR IN THE WITNESS-BOX.

It is but recently that we have had occasion to comment on the discreditable position occupied by medical men of the highest rank in their capacity of rival witnesses in a court of law. We took occasion to say that the rôle of paid partisanship which medical witnesses frequently accepted was dishonourable both to themselves and to

their profession, and that the exhibitions of cross swearing upon trials in which medical expert evidence was required, had degraded in the public mind the value of such testimony, and even called in question the good faith and the veracity of medical men.

The effect of such evidence upon the minds of jurors and upon the course of justice received a further illustration at the Middlesex Sessions the week before last. Three men had been tried for a violent assault on a policeman, and the jury, to the surprise of every one, found one of them guilty of a common assault *only* on the officer while in the execution of his duty, and not of an assault occasioning grievous bodily harm, and they also expressed their disapproval of the way in which the evidence on the part of the prosecution had been presented to them.

For this verdict, which appeared ridiculously inconsistent with the savagery of the assault, the jury was taken to task by the morning papers, and the foreman therefore considered it necessary to offer to the judge an explanation of the reasons which actuated the jury in coming to such a decision. He said that, as their verdict appeared to have created some surprise, he was anxious to state the grounds of their decision. He then explained the difficulty they had experienced in dealing with the medical evidence, on account of its indecisive character. Mr. Serjeant Cox, the presiding judge, then observed that he concurred in their opinion as to the medical evidence.

It is plain that, if medical experts can do no more than muddle the intelligence of jurors by contradictory swearing, professional evidence will speedily fall to a discount, and it is, in the interest of the profession, greatly to be regretted that members of the profession should take so false a view of their position as to assume that they are paid to swear whatever their employer requires. We are well aware that medical witnesses are incapable of giving evidence which they know to be biased or inaccurate; but a perusal of the testimony on many trials has forced upon us the conviction that they are frequently induced to see the facts from but one point of view, and, within their own mind, to shape the facts into a consistency with the case of their employers. Unprejudiced scientific medical testimony, we regret to say, is but rarely submitted to juries.

## Notes on Current Topics.

### The Genesis and Propagation of Cholera.

THE International Sanitary Conference has had this question, amongst others equally important, under its discussion, and has arrived at certain definite views, which are published by the *Practitioner* in its issue of the current month, and which we think well worthy of being reproduced in our columns. These conclusions were submitted to the Conference as resolutions, and, in the majority of instances, adopted with unanimity.

I. *Endemicity and Epidemicity of this Disease in India.*—Asiatic cholera, susceptible of spreading (epidemically), is spontaneously developed in India, and when it breaks out in other countries, it has always been introduced from

without. It is not endemic in any other country but India.

II. *Questions of Transmissibility.*—1. *Transmissibility by Man.*—Cholera is transmissible by man coming from an infected medium; but man is not considered as the specific cause, apart from the influence of locality; he is regarded as the propagator of cholera when he comes from a place where the germ of the disease already exists.

2. *Transmissibility by Clothing, Linen, Bedding, &c.*—Cholera can be transmitted by personal effects coming from an infected place, especially such as have served for the sick from cholera; and certain facts show that the disease can be carried to a distance by these effects if shut up so as to prevent free contact with the air.

3. *Transmissibility by Foods and Drinks.*—(a) *Foods.*—The Conference not having conclusive proofs of the transmission of cholera by foods decided by eleven States against seven that it was not justified in coming to a decision on this question.

(b) *Drinks.*—Cholera can be propagated by drinks, particularly by water.

4. *Transmissibility by Animals.*—No proof exists of the transmissibility of cholera by animals, but it is reasonable to admit the possibility of such transmission.

5. *Transmissibility by Merchandise.*—Although proof is wanting of the transmission of cholera by merchandise, the possibility of such transmission in certain conditions should be admitted.

6. *Transmissibility by Cholera-corpses.*—Although it is not proved that cholera-corpses can transmit cholera, it is prudent to consider them dangerous.

7. *Transmissibility by the Atmosphere alone.*—No fact is yet known which proves that cholera can be propagated to a distance by the atmosphere alone, whatever its condition. Moreover, it is a law, without exception, that an epidemic of cholera is not propagated from one place to another in a shorter space of time than it takes man to travel.

The surrounding air is the principal vehicle of the generative agent of cholera; but the transmission of the malady by the atmosphere, in the immense majority of cases, is restricted to the close vicinity of the focus of emission. As to facts asserted of transportation to a distance of one or many miles, they are not conclusive.

8. *Action of the Air upon the Transmissibility.*—It results from a study of the facts that in free air the generative principle of cholera rapidly loses its morbid activity; but that in certain conditions of confinement this activity may be preserved during an undetermined time. Great deserts form a very efficacious barrier against the propagation of cholera. This disease has never been imported into Egypt or Syria, across the desert, by caravans from Mecca.

III. *Duration of Incubation.*—In almost every case the period of incubation—that is to say, the time which elapses from the moment when an individual has contracted the choleraic intoxication to the commencement of the premonitory diarrhoea or of confirmed cholera—does not exceed a few days. All the facts cited of a more prolonged period of incubation refer to cases which either are not conclusive, or in which the premonitory diarrhoea has been included in the period of incubation, or in which

contamination (the contraction of the choleraic intoxication) has occurred after departure from the infected place.

Observation shows that the duration of the choleraic diarrhoea called premonitory—which must not be confounded with other kinds of diarrhoea that may exist where cholera prevails—does not exceed a few days.

The facts instanced as exceptional do not prove that cases of diarrhoea of lengthened duration belong to cholera and are susceptible of transmitting the malady, when the person affected is removed from all cause of (choleraic) contamination.

IV. *Questions as to Disinfection.*—Are any means or processes of disinfection known by which the generative or contagious principle of cholera can be *certainly* destroyed or deprived of its intensity?

Are any means or processes of disinfection known by which the generative or contagious principle of cholera can *with some chance of success* be destroyed or deprived of its intensity?

Science does not yet know any certain and specific measures of disinfection; but the great value of hygienic measures, such as ventilation, thorough cleansing, &c., is to be recognised, combined with the use of the substances regarded as disinfectants.

#### Determination of Sex ante Partum.

A VALUABLE contribution to what is already known on this subject has been recently made by Drs. Strong and Steele to the Chicago Medical Society, and which is reported in full in the last number of the *Chicago Medical Examiner*.

It is, as our readers know, claimed that the pulse of the female foetus is uniformly much faster than that of the male, one observer establishing a difference between them of fifteen or twenty pulsations per minute. It is also claimed that the presentation may be actually determined by noting the point at which these sounds are most distinctly audible.

Some writers have been very enthusiastic in defence of the opinions founded upon their observations. Frankenhauser, for example, gravely asserts that in fifty cases which he examined, his diagnosis was in every instance correct. In an article on "Fœtal Physical Diagnosis," by Dr. Wilson, the writer says he has "kept accurate notes of all the cases met in hospital or private practice, diagnosing the sex in each, failing only in nine cases out of 109."

On the 1st of February the authors commenced a series of observations, in order to ascertain in what percentage of cases predictions as to sex could be verified, and have each kept a careful record of fifty separate cases in which observations have been made since that date. From these it will appear that the disparity between the pulse of the male and the female infant is not as great as that established by other observers, and that, as a consequence, the ability to predict the sex of the foetus in utero is far from flattering.

The stethoscope was found preferable to the unaided human ear in noting the cardiac pulsations, since the latter are limited to a space but two or three square inches in extent. It should be added that, for convenience, we divided the uterine tumour, by four imagi-

nary right lines, into four equal parts, designated as the right and left upper, and the right and left lower quarters. It is stated that if the heart pulsates in the lower half of the abdomen, the vertex presents; if in the upper, the breech is the presenting part; and, furthermore, that the occiput or coccyx will be on that side of the median line where the heart sounds are most distinctly audible.

The foetal pulse, it appears from these observations, is subject to the same variations as that of the adult, only in a much more marked degree. While the child is perfectly quiet the heart is tolerably uniform in its pulsations, but by the least movement the pulse is greatly accelerated, increasing thirty to forty beats in the minute. Throughout a natural labour the action of the heart is variable, so much so that in the majority of cases when observation only was made at this time, the prognosis proved to be incorrect. During the first part of a pain the pulse is greatly accelerated, but as the uterus contracts more firmly and the child is subjected to greater pressure, it falls considerably; as the pain disappears it rises above the normal rate, and if the interval lasts a few moments, it again falls and becomes regular and more rapid than before labour began. From these facts relative to the variable action of the foetal heart, it is evident that the examination *must be repeated at different intervals and during the time that the child is perfectly quiet*; and that the average result of such examination, since it is an approximation to the true state of the pulse, can alone be of possible service in determining the sex of the child.

Of the first fifty women examined, there were:

Multiparæ, 13; primiparæ, 37.

From the statistics quoted by the authors, they deduce the following observations:—1. In the majority of cases male foetal hearts are slower than female. 2. 132 foetal pulsations per minute is the average which constitutes a dividing line between the sexes. Below this, sixty-eight and four-sevenths per cent. are males, twenty per cent. are females, eleven and three-sevenths per cent. are doubtful. Above this fifty-three and one-third per cent. are females, twenty-six and two-thirds per cent. are males, twenty per cent. doubtful. We have here, it may be observed, another demonstration of the fickleness of the female heart. 3. The most accurate observations are made during the last four weeks of gestation. 4. The rapidity of the heart's action is increased in proportion to the feebleness of the foetus. 5. Calcareous or fatty degeneration of the placenta renders the pulsations feeble and irregular. 6. In some cases it would be possible to diagnose diseased conditions of the placenta from careful observation of the foetal heart.

Of fifty cases examined consecutively, twenty-seven gave birth to female children, and twenty-three to males. The lowest rate observed was 118; it occurred but twice; one each in a male and female child. The highest rate noted was 180, occurring three times, twice in males and once in the case of a female. The average rate of the male pulse was 136.3; of the female, 137; of both sexes, 136.7. Considering the latter as the dividing line between both sexes, a pulse at and below this rate may be referred to males, and that above it to females. In twenty-six cases the sex was correctly predicted, and in twenty-four an error was made.

In regard to determining the presentation, we can report more favourably, having been correct in forty-nine out of fifty cases. The case of failure was one where the breech was the presenting part, but the examination was not made till the second stage of labour.

In conclusion, it may be generally stated that the authors find an opinion as to the sex of the child, founded on the rate of the foetal pulse, to be of little more value than a guess, while the presentation, generally, and the exact position, possibly, may be accurately determined.

### The Physiological Action of Prussic Acid and the Antidotal Value of Atropine.

THE *Practitioner* for the current month recapitulates at considerable length a record of the researches of Dr. Boehm, of Dorpat, into this subject, undertaken by him for the purpose of verifying the previous investigations of Preyer. The experiments had been made upon cats and rabbits, and the conclusions arrived at are as follows:—

1. The operation of prussic acid is directed upon the central nervous system, whose functions are annihilated by large doses, after a brief excitement or increase.

2. The lesions of respiration and circulation arise from analogous changes in the activity of their centres in the medulla oblongata.

3. The vagus plays no part, either in the effect of prussic acid on the respiration, or in its effect upon the heart.

4. Atropine is not an antidote to prussic acid. The only rational treatment of this poisoning is the persevering performance of artificial respiration.

### Possibility of Cinchona Cultivation in Ireland.

A CORRESPONDENT has forwarded to us copies of the *Overland Ceylon Observer*, containing a very elaborate article upon the cultivation of the cinchona in Ceylon, from which it appears that the plant has been successfully naturalised in that country, and with every prospect of successful and lucrative cultivation.

The author notices the importation of some plants of the *Cinchona crispera*, and says "this plant ought to answer at our very highest elevations, for it stands frost—in fact, Mr. Cross found it growing on the summit of the highest mountains around Loja, where the temperature occasionally falls to 27°. The climate of Killarney (mean summer temperature, 59½°; winter, 44½°, and therefore closely approaching the climate of Newera ELLIYA), which suits the arbutus so well, Mr. Howard thinks would answer for this variety of cinchona."

The experiment thus hinted at is certainly worth trying, and perhaps some of our readers in or near Killarney may be disposed to make the attempt. It would be a strange event if the arbutus of the Irish Switzerland should some day be replaced by the cinchona tree, and if London chemists should send for the raw material of their quinine to Kerry instead of Ooctacamund.

### Small-pox Inoculation in Ireland.

WE noted recently an alarming report as to the prevalence of the crime of small-pox inoculation in the county Mayo, and we observe that the Irish Local Government Board have forwarded to the Lord Lieutenant the letter

of the medical officer of the district, in order that the police might be put in action.

One prosecution has taken place at Kiltamagh, and the inoculator was sent for trial. It seemed to have been admitted that the victim was inoculated, but the defendant's case is that the inoculation failed, but that the child took the contagion in the usual course and died. More than a month is said to have elapsed between the inoculation and the appearance of the disease.

By the way, we are surprised that the English anti-vaccination fanatics have not got up a petition to the Queen, or a defence fund, or a testimonial, or something of the sort, in approval of these inoculators, and in consistency with their peculiar views about the liberty of the subject and the right of every free Briton to have small-pox or syphilis if he likes.

### Special Position for the Reduction of Dislocated Vertebrae.

A MAN, *æt.* 41, fell under a weight he was carrying on his shoulders. He yielded down on his knees, and was lifted up unconscious, and with a marked dislocation of his 11th dorsal vertebra, which also had its spinous process broken off, as well as those of the 9th and 10th. There was complete paralysis below the fracture. Reduction was attempted unsuccessfully, when Dr. Bliss had the patient laid on the ground, put assistants at each extremity, bent the spine firmly in an arch, supported by the knees, and the surgeon then pressed strongly on the dislocated vertebra and easily reduced it. The spinal column immediately resumed its shape, and in three minutes the patient was able to move his feet and sensibility immediately reappeared.

### Relief of Cerebral Abscess by the Trephine.

At a recent meeting of the Association Française a case of a young man, *æt.* 18, was shown, where trephining of the skull had been performed for the cure of cerebral abscess with perfect success. There was no imperfection remaining of either mind or body.

### The Growth of Specialities.

THE *Lancet* publishes the following amusing *jeu d'esprit* from the pen of Dr. Barnes:—

"I have been recently honoured by a visit from a lady of typical modern intelligence, who consulted me about a fibroid tumour of the uterus; and, lest I should stray beyond my business, she was careful to tell me that Dr. Brown-Séquard had charge of her nervous system; that Dr. Williams attended to her lungs; that her abdominal organs were entrusted to Sir William Gull; that Mr. Spencer Wells looked after her rectum; and that Dr. Walshe had her heart. If some adventurous doctor should determine to start a new speciality, and open an institution for the treatment of disease of the umbilicus—the only region which, as my colleague, Mr. Simon, says, is unappropriated—I think I can promise him more than one patient."

### Assessment of Salaries by the Local Government Board.

IT may be in the recollection of our readers that, when the late physician to the Galway Fever Hospital recently resigned his office, he was granted a superannuation

allowance, and his son was appointed to succeed him. The guardians, much to their own satisfaction, no doubt, came to a cheap arrangement to cut off from the salary of the newly-appointed physician the amount of his father's superannuation, and they, no doubt, calculated by this means to pension the late medical officer at his son's expense. The Local Government Board, however, determined that the interests of the hospital should not be prejudiced by any such family arrangement, and they insisted that the guardians should pay a reasonable remuneration, and, finally, were obliged to issue a sealed order fixing the salary at £60, being double the amount decided upon by the guardians. We observe that a memorial to the Lord Lieutenant against this action of the Local Government Board had to be abandoned by its promoters because only a few of the guardians would sign it.

The episode is an insignificant one in itself, but it enunciates a principle which may prove very valuable in reference to the working of the Public Health (Ireland) Act.

It is not at all improbable that many boards of guardians—newly-dubbed “Rural Sanitary Authorities”—will be hostile to any sanitary improvements (many of their members being themselves proprietors of dung-heaps and cesspools which would need reform), and, as they are compelled to appoint a sanitary staff, will endeavour to defeat the attempt at cleanliness by voting farcical salaries for their health officers.

It is no secret that the Dublin Corporation are in this position, and it is anticipated that they will attempt to snub the Metropolitan dispensary medical officers (who have bored them with reports of fever nests and other insubstantial developments), by fixing their salaries at £5 a piece, or such sum as will effectually prevent their performing any efficient duty as medical officers of health.

In view of this probability, we are gratified to observe that the Local Government Board are conscious of their power over obstructive guardians and corporations, and will be prepared to put on the screw when the public interest requires it. As far as the Dublin Corporation is concerned, a dire experience enables us to anticipate the course of events. No doubt every poor relation of a corporation who—by any stretch of imagination—can be conceived qualified for appointment, will be a candidate for some of the “little pickings” in course of distribution. The religious screw and the personal whip will be in full exercise, and in the event we shall no doubt see many of the public health offices filled by men whose only mark is their curious incompetency for their duties.

### Unreal Bouquets in Wine.

THE falsities of Cetto and Hambro' sherries are a thrice-told tale; and it is only a week since we were informed by the morning papers that a confectioner essayed to defend a charge of having sold wine without a licence by asseverating that the liquor was only “British” port, sold at 2d. a glass, and, he believed, not containing one drop of wine.

Most of our readers may think that all this is nought to them, and have too much confidence in the education of their noses to believe that they might be taken in even

in the bouquet of their nectar. Little do they think that the aroma in which they luxuriate may be a vile chemical compound, concocted, perhaps, from the dirtiest sources, for the purpose of deceiving their olfactory sense, and inducing them to admit to their unhappy stomachs a compound against which their noses should keep guard. Nevertheless, it is true. The *Chemist and Druggist* acknowledges to have received from Dr. Ludwig Raab, Professor of Chemistry in Straubing University, specimens of “œnanthyllic, caprynic, caprylic, butyric, and baldrianic ethers, made specially by the learned Professor for the improvement of low-class wines.”

Some of these ethers, he says, are those which, by the natural process of fermentation, give the aroma to Bordeaux, some to Hungarian wines, and some are added to whisky to make it into cognac; and he claims to have superseded the troublesome process of distilling these products from wine refuse by a secret method of making them artificially. Henceforth wine-makers need not be at the trouble of waiting and watching for a perfect fermentation, but can produce their Chateau Lafitte or Steinberg Cabinet *au choix* by the addition of a dash of Professor Raab's ether.

### A Poor-law Catechism for Guardians.

WOULD it be considered an impracticable suggestion if we advised that Poor-law guardians should be considered ineligible to sit until they had passed an examination in the rules and regulations which govern their duties and authorities?

If such an arrangement could be enacted, the Irish Poor-law Service would be saved a great deal of misspent time and unnecessary declamation, for there is not a board of guardians in Ireland which is not constantly occupied by stump speeches and village debates upon matters in regard to which they have no choice whatever. At Borrisokane lately the greater part of a sitting of the board was occupied by a discussion as to whether the medical officer should be compelled to provide instruments for his public duties at his own expense, and several rural Demosthenes aired their eloquence in advocacy of the affirmative. If the Poor-law Acts and regulations had been known to the guardians they would have been aware that such a proposal is totally illegal, and that if they refused to supply their officers with all necessary appliances he would be perfectly justified in declining to treat the patients, and assigning to the Local Government Board as his reason that he did not possess essential facilities.

### Reappearance of Black Plague.

FROM Egyptian sources we are informed, says the *France Médicale*, of a new plague which has not appeared now in Europe for several centuries. It seems to be nothing less than the black plague which formerly depopulated Florence, and it is certain that it has appeared in great extent in the neighbourhood of Mecca and Medina. The official reports from these places give the most frightful description of this horrid disease. Its chief symptoms consist in the formation of buboes, which, once they appear, leave no hope of recovery. Dr. Pasqua, who is the sanitary

inspector, declares that this affection is of a true epidemic-contagious character.

The Egyptian Government has already taken the precaution of establishing a strict sanitary *cordon*; but it is to be feared that these precautions will be of small avail, as the time of the great *Ramazin* is now at hand, during which hundreds of thousands of pilgrims will go to Mecca as a sacred duty, who will doubtless run a great chance of importing this infection when they leave. Italy is already very much alarmed as to the possible importation, and has taken means accordingly; but unless the Governments of Europe urge the adoption of active measures on the Mussulman authorities grave results may be anticipated.

### Carnivorous Plants.

ONE of the most interesting and instructive communications to the British Association was contributed to the Sub-Section of Zoology and Botany, by Dr. Hooker, on what he termed "The Carnivorous Habits of some of our Brother Organisms—Plants." He said: Various observers have described with more or less accuracy the habits of such vegetable sportsmen as the Venus flytrap and the pitcher plants, but few have inquired into their motives and the views of those who have most accurately appreciated them. These have not met with that general acceptance which they deserved. Quite recently the subject has acquired a new interest from the researches of Mr. Darwin in the phenomena which accompany the placing albuminous substances on the leaves of *drosera* and *pinguicula*, and which in the opinion of a very eminent physiologist prove in the case of *drosera* that this plant digests exactly the same substance and in exactly the same way that the human stomach does. With these researches Mr. Darwin is still actively engaged, and it has been with the view of rendering him such aid as my position and opportunities at Kew afforded me that I have, under his instructions, examined some other carnivorous plants. About 1768, a well-known English naturalist sent to Linnæus a drawing of a plant, to which he gave the poetical name of *Dionæa*. He said "the plant shows that nature may have some views towards its nourishment in forming the upper joint of its leaf like a machine to catch food. Upon the middle of this lies the bait for the unhappy insect that becomes its prey. Many minute red glands that cover its surface, and which perhaps discharge sweet liquor, tempt the poor animal to taste them, and the instant these tender plants are irritated by the feet the two lobes rise up, grasp it fast, lock the rows of spines together, and squeeze it to death." Linnæus only saw in these wonderful actions an extreme case of sensitiveness in the leaves, which caused them to fold up when irritated, just as the sensitive plant does, and he consequently regarded the capture of the disturbing insect as something merely accidental, and of no importance to the plant. He was, however, too sagacious to accept Ellis's sensational account of the *coup de grâce* which the insect received from the three stiff hairs in the centre of each lobe of the leaf. For another generation the history of this wonderful plant stood still, but in 1868 an American botanist (Mr. Cranby), who is still happily engaged in botanical research, was staying in the *Dionæa* district, studying the habits of the plant pretty carefully, especially the points which Dr. Curtis had made out. His

first idea was that the leaf had the power of dissolving animal matter, which was then allowed to flow along the somewhat trough-like retiole to the roof, thus furnishing the plant with highly nitrogenous food. By feeding the leaves with small pieces of beef he found, however, that these were completely dissolved and absorbed, the leaf opening again with a dry surface, and ready for another meal, though with an appetite somewhat jaded. He found that cheese disagreed horribly with the leaves, turning them black, and finally killing them. Finally, he details the useless struggles of *curculio* to escape as thoroughly establishing the fact that the fluid already mentioned is actually secreted, and is not the result of the decomposition of the substance which the leaf has seized. It is a generalisation now—almost a household word—that all living things have a common bond of union in a substance always present, where life manifests itself, which underlies all their details of structure. This is called protoplasm. One of its most distinctive properties is its aptitude to contract, and when in any given organism the particles of protoplasm are so arranged that they act, as it were, in concert, they produce a cumulative effect, which is very manifest in its results. Such a manifestation we possibly have also in the contraction of the leaf of *Dionæa*. Not merely are the phenomena of digestion in this wonderful plant like those of animals, but the phenomena of contractility agree with those of animals also. To Mr. Darwin, who, for some years past, has had the subject under investigation, we are indebted, not merely for the complete confirmation of the facts attested by the earliest observers, but also for some additions to those facts which are extremely important. The whole investigation still awaits publication at his hands, but some of the points which were established have been announced by Professor Asa Gray in America, to whom Mr. Darwin had communicated them.

### Practical Cremation.

WE have had a very disagreeable and disgusting sensation within the last few weeks, a sensation which, remarks *The Missouri Clinical Record*, has opened our eyes to the existence of the most loathsome crimes in our very midst. Madame Fortmeyer, a midwife, was arrested by the police for committing an abortion upon a young mulatto girl who died in consequence of the operation. At the coroner's inquest, among other horrible details, it was proved that Madame Fortmeyer not only unscrupulously resorted to this infamous business as a means of livelihood, but that she had a unique and original method of ridding herself of all tell-tale evidence. A favourite aphorism with her was, "*ashes tell no tales*."

This very pleasant and amiable person indulged in the pastime of burning the results of conception; and it was shown at the inquest that she had roasted in her stove the bodies of living, breathing infants.

Madame Fortmeyer's body will probably offer a fitting specimen for publicly and practically illustrating the subject she appeared so fond of in private.

A GIRL named Amelia Andrews, one of the children who was bitten by a mad dog in Walworth in March last, died of hydrophobia last week.

**Workhouse Milk.**

THE Abbeyleix Guardians have prosecuted their milk contractor, Mr. Richard Seale, for cheating them in the milk, and the magistrates have fined him £10 and £10 costs. Very good so far as it goes—probably about two months' profit of the fraud. Somewhere else in Ireland the guardians, through their analyst, Dr. Cameron, have detected 60 per cent. of water, and we may venture to hope that they will follow the precedent shown them at Abbeyleix.

**Accident Ambulances.**

THE *Philadelphia Reporter* announces that that city has established an ambulance system in connection with one of her great hospitals, that on the west bank of the Schuylkill. The station is in telegraphic communication with all the police stations, so that a summons for medical aid and for an ambulance may be sent from any section. A surgeon will be promptly despatched, with all needful appliances, to the scene of accident, and thus it is hoped much good may be done, and perhaps many lives may be saved.

**Pharmaceutical Qualifications in England.**

THE new regulations of the London Board of Pharmaceutical Examiners come into force on October 1 next. Candidates will be required to prove the possession of a practical acquaintance with the elements of qualitative analysis, which will probably be tested by the submission of certain solutions, the chief ingredients of which will have to be detected. Correct ideas in respect to doses, and a more accurate knowledge of the chemical and pharmaceutical processes by which Pharmacopoeia products are obtained, are the points of advanced severity which will henceforth be demanded. The regulation requiring a certificate that the candidate has attained the age of twenty-one will come into force on January 1, 1875, and that necessitating a previous three years' pupillage to the business on January 1, 1877.

**Priestley Celebration in America.**

THE *Chemist and Druggist* records the centennial of American chemists at the grave of Priestley, on August 1, which seems to have been an interesting, if a somewhat romantic event. Northumberland, on the banks of the Susquehannah, is said to be a beautiful spot, and there something like a hundred scientific chemists gathered to do honour to the memory of the extraordinary man who discovered oxygen that day a hundred years ago. Priestley's poor lot of chemical apparatus was on exhibition, and some of his descendants came from remote parts of the universe to meet the pilgrims. After a series of addresses in his honour, the assembly was ultimately adjourned in proper form until August 1, 1874.

**Hospital Saturday.**

THE weekly meeting of the Executive Committee of this fund was held on Saturday last, at St. John's Hospital for Skin Diseases. It was announced that in addition to the public meeting in the Guildhall, on Saturday, the 3rd of October, at which the Lord Mayor will take the chair,

there will be an open air demonstration in Hyde Park, on Saturday, 10th proximo, at which Archbishop Manning has promised to preside. It was further announced that permission had been given for collection boxes to be placed in each of the district post offices, and Capt. Mercier submitted a letter from Brigadier General Sir J. M. Adye, Director of Artillery, giving official sanction for collection boxes to be placed for voluntary contributions at the entrance gates of the Woolwich Arsenal. After the customary votes of thanks the meeting separated.

**Public Funeral of a Lady Hospital Nurse in London.**

ON Saturday the remains of Miss Louisa Eliza C. Coles, the lady superintendent of the British Nursing Association, and of the nursery departments of the Royal Free Hospital, were interred in Highgate Cemetery. The funeral consisted of an open hearse, the coffin being covered with a white velvet pall, followed by six mourning coaches and several private carriages, which contained General Sir Arthur Lawrence, K.C.B.; Major-General Eardley Wilmot, Major Elliott, Sir Kingsmill Key, Mr. Hart, Mr. Gant, Mr. J. D. Hill, and other gentlemen connected with the hospital and associations. The burial service of the Church of England was read by the Rev. J. Johnson, at the conclusion of which bouquets of flowers were placed on the coffin. General Wilmot briefly addressed the mourners in a most impressive speech, and after the singing of a hymn the assemblage slowly left the ground. The line of route was thronged by persons of both sexes who had been nursed under the supervision of deceased.

THE last of the elections caused by the decease of the late Joseph Ferguson, Esq., M.D., took place last week at the Westmeath County Infirmary, when Dr. Wm. Henry Middleton was unanimously elected as future surgeon to that institution.

IT is proposed to establish a College of Science and Literature in Bristol, and to incorporate with it the Medical School which has existed in that city for many years. The institution will be analogous to the Queen's College in Birmingham, and Owens College in Manchester.

MR. GEORGE MAHOOD FOY, F.R.C.S.I., has been unanimously elected to the Chair of Forensic Medicine in the Carmichael School of Medicine, Dublin.

MR. EDWARD WARREN, of Cairo, has been promoted by His Highness the Khedive of Egypt to the position of Chief Surgeon of the Egyptian Army.

THROUGH the exertions of Mr. Dunbar, M.P. for New Ross, there has been secured out of the Civil List Fund a pension of £50 a year, on their joint and several lives, for the sisters of the late Surgeon F. J. Macarthy, of the Army Medical Staff, who, when returning home, invalided from fever, on board the *Victor Emmanuel*, committed suicide by getting out of a porthole of the vessel.

THE French Government has offered a prize of £12,000 for the discovery of an effectual means of destroying the vine scourge, *phylloxera*; and a committee has been appointed to regulate the mode of competing, and to award the prize, should anyone prove himself the fortunate discoverer.

SURGEON-MAJOR PORTER, Assistant-Professor of Military Surgery at Netley, has been presented with the Bronze Cross by the French Societies for Aid to Sick and Wounded of Armies, in recognition of his services during the late Franco-Prussian war.

MR. PRIME-BARTLETT was presented last week with a testimonial of silver plate by the servants and nurses of the Brompton Consumption Hospital on the occasion of his resigning the post of Assistant Resident Medical Officer to that institution.

THE Manchester and Salford Sanitary Association has circulated some excellent instructions for the avoidance and prevention of enteric fever and scarlatina, and which are intended for general distribution.

THE executors to the will of the late Miss Hannah Brackenbury, who, it may be remembered, bequeathed the magnificent sum of £10,000 to Owens College, have kindly presented a donation of £500 to the University College Hospital, from the funds left by that lady for distribution to charitable purposes.

DR. THORNE THORNE, one of the Local Government Board inspectors, reports an epidemic of typhoid fever in the hamlet of Brierly Lane, Bradford. Seventy persons have already been attacked with the disease.

OF the £7,500 required for the proposed monument to Liebig, in Germany, nearly two-thirds have been subscribed.

THE Registrar-General reports during the week ending last Saturday, 5,343 births and 3,345 deaths in 21 large cities and towns of the United Kingdom. The average rate of mortality in these towns was 23 per 1000.

AN Indian telegram, received from Shillong last week, announces the death of Dr. Macdonald, Deputy Surgeon-General of that place. He was suffering from dysentery, and had only recently returned from furlough.

ACCORDING to the latest returns of the Registrar-General, "scarlet fever and small-pox continue fatally prevalent in Birmingham." So much importance do the sanitary authorities of Northampton attach to the outbreak that, acting under the advice of their medical officer of health, Mr. Alfred Haviland, they telegraphed to Birmingham on Saturday, advising the postponement of the Annual Onion Fair, which is usually attended by large masses of people from neighbouring towns, Northampton in particular.

OPPONENTS of alcoholism will not be gratified with the statistics. In the first half of the year 1874 duty was paid on 13,887,923 gallons of home-made spirits retained for consumption in the United Kingdom as beverage, being 662,639 gallons more than in the corresponding half of the previous year. The quantity so retained in England was 7,832,320 gallons, an increase of 586,449 gallons; in Scotland, 3,131,597 gallons, an increase of 182,655 gallons; in Ireland, 2,924,006, presenting the unusual return of a decrease amounting to 106,465 gallons. The quantity of foreign and colonial spirits, not sweetened or mixed, entered for consumption in the United Kingdom in the half-year, was 4,915,927 proof gallons, being 87,422 gallons more than in the corresponding half of the preceding year.

## Literature.

### KLEIN ON THE LYMPHATIC SYSTEM. (a)

THIS monograph of the lymphatic system is a most valuable addition to our knowledge of perhaps one of the most difficult subjects in histology. The volume now under consideration forms the first part of a series, and is devoted to the anatomy of the serous membranes, both in health and disease. The work is divided into two sections, of which the first, by far the larger, treats of the normal histology of the serous membranes; the second, of these structures under morbid conditions—viz., acute or chronic inflammation, including special reference to the pathology of tubercle. Portions of the work have already appeared in the *Quarterly Journal of Mic. Sci.* and *Centralblatt für Med. Wiss.* for 1872. The methods of preparation employed by Dr. Klein in these investigations have been principally those of staining with one-half per cent. solution of nitrate of silver, aided by the examination of the fresh tissues in serum, or one-half per cent. solution of chloride of sodium.

The first chapter treats of the endothelium of the free surfaces of the serous membranes, for a general description of which the reader is referred to the works of Recklinghausen, Auerbach, and Schwegger-Seidel, special attention being drawn to certain points that have not yet been sufficiently understood, the most noticeable point being the normal germination of the endothelium of the peritoneum and pleura mediastini of guinea-pigs, cats, dogs, and monkeys.

Instead of the elements being everywhere flattened, more or less hyaline cell plates, there are groups of polyhedral, club-shaped, or even short columnar cells, containing nuclei and sharp-outlined large shining nucleoli. These areas vary in size and number, being more abundant in young animals, and very much exaggerated in acute or chronic inflammation. Dr. Payne described these appearances in the human omentum in a paper communicated to the Medical Microscopical Society as early as June, 1873.

The nuclei of these germinating endothelial cells are generally in a state of division, and the appearances seem to justify the conclusion arrived at by Dr. Klein, that germination goes on with some rapidity, and, as a result, there are always to be found on these patches numbers of small, spherical, nucleated cells, resembling in every respect lymphatic cells, some wholly, others partly detached from the surface. At the end of this chapter Dr. Klein discusses the cause of the silver lines. He very clearly proves the commonly received opinion that the lines are due to the staining of an intercellular substance, in opposition to Schwegger-Seidel, and others, who have tried to show

(a) "Anatomy of the Lymphatic System." By E. Klein, M.D., Assistant-Professor at the Laboratory of the Brown Institution, London. Vol. I. The Serous Membranes. London: Smith, Elder, and Co.

that they correspond to a precipitation in a serous fluid which has accumulated in furrows on the surface of the endothelium, the endothelial cells being somewhat convex on their upper surface, and to Robinski, who altogether denies the existence of an intercellular substance.

The second chapter deals with the cellular elements of the ground substance. These elements are large, flat, branched cells, lying parallel to the surface, and in spaces which communicate with each other by numerous branched and unbranched canaliculi of different breadth and length. These canaliculi and lacunae contain small lymphoid corpuscles. This arrangement corresponds to the lymph canalicular system of Recklinghausen. Rollett maintains a similar view as regards the cellular elements of the cornea. The flattened cells of the ground substance are more closely accumulated in some parts, so as to form distinct nodules in the membrane; in the delicate reticulum of these nodules may be seen numbers of lymphoid cells, which are supposed to be offsprings of the branched cells of the stroma. These structures are sometimes converted into fat tracts.

In this chapter are also described the relations of fat tissue and the lymphangeal structures to the lymphatics. To render comprehensive the remarks on the development of fat—so far as it relates to the present subject—a description is given of the well-known gelatinous body composed of rudimentary adipose tissue, situated in the infra-orbital fossa of young rabbits and guinea-pigs.

The third chapter gives an account of the lymphatic vessels of the serous membranes; it is divided into five portions. The first consists of a description of the arrangement in the omentum and pleura mediastini. The lymphatics are of two kinds—vessels and capillaries; the former possessing valves and the endothelial elements fusiform in shape, whilst the latter are lined with sinuous endothelium and are valveless. The lymphatic vessels are principally found to accompany the blood-vessels; a vessel may have running along with it one or two lymph-vessels. It sometimes occurs that the blood-vessel runs within the lymphatic—the blood-vessel is, in fact, invaginated, so that in these cases at least there may be seen perivascular spaces; but the lymphatics are also distributed independently of the blood-vessels in many parts. Concerning their structure little is given but what is already known. In the lumen of the lymphatics there swim a number of corpuscles of various sizes, exhibiting amoeboid movements.

In this part of the chapter a very important question is discussed—viz., do the lymphatics form a closed system, or do they take origin among the tissues? Dr. Klein concludes that they, together with the serous cavities, form a closed system.

The lymphatic system of the centrum tendineum of the diaphragm constitutes the subject of the second part of this chapter; both the methods of demonstration and the results of Dr. Klein's investigation agree with those already published by Recklinghausen and Ludwig.

The third portion is devoted to a description of the lymphatic vessels of the mesentery. This membrane possesses two kinds of vessels—first, those which run from the intestine into the mesenteric glands, and, secondly, vessels which belong to the mesentery itself. The vessels of the first kind accompany the large blood-vessels to the intestine, and are provided with a rich circular muscular coat and numerous valves.

The relation of the lymphatic vessels to the surface of the serous membranes is considered in the fourth part, which contains, in addition to other matter, a description of the two kinds of stomata seen on the serous surface—stomata vera and stomata spuria or pseudo-stomata, the former of which represent the mouths of true lymphatics, and are again of two kinds, those representing the mouths of vertical lymphatics, channels leading into lymphatic vessels, and those leading into simple lymphatic sinuses. The latter consist of processes from the branched cells of the ground substance projecting freely between the endothelial elements, and are hence called stomata spuria. The stomata vera are lined by a special layer of more or less polyhedral cells.

The remainder of the chapter contains an account of the development of lymphatic capillaries.

The blood-vessels of the serous membranes form the subject of the fourth chapter. The distribution of blood-vessels in general is not gone into. The most important part of the chapter is the discussion of the development of blood-vessels and capillaries from the branched connective tissue corpuscles. Both blood and lymphatic capillaries develop by the vacuolation of these corpuscles, which may or may not be connected with pre-existing vessels by their long delicate processes. To Stricker is due the credit of pointing out this fact, who first observed it in the tadpole's tail; his observations have since been confirmed by Arnold.

For a description of the pathological condition we must refer our readers to the original memoir. Suffice it to say that in many instances the processes are of the same nature as those seen under normal conditions, but more active.

It is a matter of extreme difficulty to present a concise yet comprehensive account of the views held by the author, for, whilst admitting the work to be one mass of valuable facts, it is often a hard matter to understand clearly the sense of some passages; not a few are certainly enshrouded in some obscurity, from their erroneous construction. We think Dr. Klein would have done well to have entrusted the revision of the text to some one thoroughly conversant with the language. As a result, many passages no doubt would have been rendered lucid, and the dogmatic tone that pervades the whole work might have disappeared.

Great credit is due to the publisher for the admirable manner in which the work has been got up; the type especially is beautifully distinct. The work is embellished by ten plates, containing fifty-four elegant figures, engraved by Bach, of Leipzig. The expense of their production was borne by the Government Grant Committee of the Royal Society.

## Correspondence.

### CRIMINAL ABORTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Apropos of Dr. Whitmore's remarks on the above subject, published in the last number of your journal, the questions arise—How is it that in America, as in France, married people shirk, to a greater or less extent, the duties and responsibilities of paternity? and is there any danger of criminal practices—abortion, as in America, and systematic non-conception by means of "safes," Onanism, &c., as in France—taking root among ourselves?

The second question, I think, may be answered in the negative, as long as our present laws of inheritance remain in force: assimilate them (and this answers the first question) to those of the United States, France, and other countries where democratic ideas, pure and simple, prevail, and the results will be minimised families and ever-increasing vices of the most debasing kind.

Yours obediently,

9th September, 1874.

CAUSE AND EFFECT.

### THE NEW PUBLIC HEALTH BILL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The new Sanitary Act will soon come into operation. Do the dispensary medical officers intend leaving themselves to the tender mercies of Poor-law guardians, or will they have courage enough to refuse to discharge important and onerous duties unless properly recompensed for such duties? I know that seven-eighths of the dispensary districts are in as wretched a sanitary condition as my own is, and I know, too, that the medical officers of these districts will have an amount of arduous and offensive duty to perform if they wish to carry out conscientiously the sanitary reform which will be legally placed in their hands. I should not, perhaps, have applied the term offensive to these duties,

but I foresee the removal of many a nuisance which has been from time immemorial a pet to its proprietor, and I know on whom the blame will fall. The relieving officer or other subordinate will have more worldly wisdom than to say "I am the man."

One-half of our present salaries was mooted as proper recompence, but I say, "Wait till we get it."

September 17th.

A DISPENSARY DOCTOR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I would suggest that in the event of sanitary authorities offering to give inadequate salaries to medical officers (as they are sure to do), that those officers, while undertaking to perform the duties, should as a body be *unanimous* in refusing to accept such, and should at once protest to the Local Government Board as to their inadequacy. In my opinion, if they once commence with and remain quiescent in accepting low salaries, they will find it difficult to get them up afterwards, notwithstanding that but half the expense will fall upon the ratepayers.

Yours,  
MEDICUS.

Kilkenny, Sept. 17th, 1874.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As the Public Health (Ireland) Act of the last session will soon come into operation, and the salaries of the sanitary officers be considered and fixed by the rural sanitary authority, will you kindly afford me some information on the following subjects:—

1. Is it compulsory on the guardians of the union, so soon as the Act comes into operation, to appoint the sanitary officer in each dispensary district under their control, as an idea is prevalent with some guardians that they are not limited by time to make such appointments, or that they need not make them at all provided that they do not consider that a necessity for such exists?

2. Are the dispensary medical officers *compelled* to accept the appointment at *any* salary a cheeseparing board of guardians may fix and determine?

3. If a dispensary medical officer refuses to accept the appointment without receiving a fair and reasonable salary, at least a salary equivalent to that granted by other boards, can they, the guardians, postpone or decline making any appointment for such district, or can they proceed to appoint a sanitary officer in his stead?

Hoping you will excuse this trouble, and at your earliest convenience enlighten an ignorant

DISPENSARY MEDICAL OFFICER.

1. The boards of guardians *must* appoint the dispensary medical officer to be the medical officer of health. They have no option, nor any discretion as to whether such an officer is required, and they must make this and other cognate appointments within a reasonable time, or the Local Government Board will make them for them.

2. The dispensary medical officers *must* accept the office at any salary which the guardians fix and the Local Government Board approve. We have every hope that an obviously insufficient assessment will not be permitted.

3. Already answered above.—ED. M. P. & C.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Public Health Bill is now law. Whilst it was in the stage of incubation the numerous readers of your independent journal must freely admit that it had your warmest advocacy, as well as that of the Irish Medical Association. It will no doubt be considered by you and the citizens of Dublin to be a great public boon as an effectual agent in quenching all the old hot-beds of disease, and in stamping out all infectious elements from both "urban" and "rural" districts. In my humble opinion the powers granted by the Bill will be utterly inert in suppressing the most fruitful sources of disease in rural districts. As long as lodging-houses can be crammed with the unwashed and wearied strollers, and as long as such lodging-houses have not a yard or rear of even the length or breadth of an ordinary man, or any form of sewer from the house beyond a small and shallow one, which I have so often seen choked in the centre of the earthen floor through which it runs to the open channel in the public street—so long as the laws of our country will

not enable the sanitary authorities to compel the owners of cabins to have them properly constructed both as regards sewage and otherwise, so long, I submit, will hot-beds of disease be found in rural districts. I am not here theorising, but am speaking from a practical experience of many years of the causes of disease in country parts. If the law will not permit the sanitary sub-officer to visit any one of these hovels, the occupier may order him out. Or if, on visiting it, and with the written opinion from the sanitary officer of the absolute necessity to have it put in a state fit for a human being to live in, that the sanitary authorities cannot compel the owner of the house to at once comply with the suggestions of the sanitary officer, it becomes evident that the nestlings of disease in rural parts will remain uncrushed. I will hope to see a thorough sewage system established by means of one deep sewer from every cabin leading into a large central one. Accumulations of filth surrounding cabins can be prevented, and thus indirectly the owners may be compelled to establish deep ash-pits. It might also be advisable to have a *dépôt* of disinfectants in every workhouse. The necessary disinfectants could be delivered at the several dispensary stations by the workhouse hospital patients' van; the latter would thus also undergo a process of disinfecting which, I think, would lessen the great objection that poor people have to be conveyed by it to the hospital. It is hoped by many that the sanitary authorities and the Local Government Board will adequately remunerate the sanitary officers for the important duties (of value to peer and peasant alike) now imposed on them.

I am, Sir, your obedient servant,

FRANK J. DAVYS, A.B., F.R.C.S., &c.

## Obituary.

### ARTHUR JACOB.

No section of his professional brethren will read with deeper regret the intelligence of the death of Arthur Jacob, which our pages this day mourn to record, than those who have known him through the intercommunication of its columns, and who—through a third of a century—have unswervingly testified their grateful reminiscences of his long and earnest services to themselves and their profession. At the advanced age of eighty-four—spared by Almighty Providence the distractions of disease or suffering—died, on Monday last, Arthur Jacob, the possessor of an European fame as an anatomist, an original investigator, a lucid and incisive writer, an ardent and disinterested advocate of the best interests of his professional brethren, an experienced and judicious diplomatist and legislator in matters affecting them. Three times President, and for a quarter of a century the trusted Councillor of the Royal College of Surgeons in Ireland, for fifty years a teacher with whose reputation men were proud to associate their names, he has carried with him to the grave the respect which all men unhesitatingly accord to unswerving integrity of purpose, unchallenged talents and unflagging ardour, and perseverance. With the simple mention of his name will rise up within the minds of his Irish compatriots a crowd of recollections now hallowed by his death—recollections which awaken to-day nothing other than gentle feelings and sorrowful respect for his memory.

With this simple record we lay aside our pen. The time and place were alike unfitting for formal eulogy, or the detail of his biography.

To utter more to-day would do dishonour to the solemnity of our thoughts, and would mar the feeling of full-hearted regret which the memory of his public life amongst them will reawaken within the breasts of the companions and pupils of the honoured dead.

## FRANCIS ANSTIE.

WE announced in our last the melancholy death of this distinguished physician, who was on the staff of our contemporary the *Lancet*, and editor of the *Practitioner*. Having had for years past personal acquaintance with the deceased, we fully endorse all that the *Lancet* says of his private worth and high professional attainments, from which we republish the following remarks, feeling acutely the grievous loss the profession has sustained in his death:—

"It is impossible, in dwelling upon the rare qualities which characterized Dr. Anstie, to separate the personal, which endeared him to his intimate friends, from the intellectual, by which his name became familiar to the profession and the public. He was a physician of the type which is the pride of English physic and the crown of our schools of medicine. Or rather it should be said he was a typical physician of this class. His intellectual culture was not inferior to his strictly medical culture, and this was of the highest. The one, in fact, formed, as it were, the fitting setting for the other. Complete in the technical knowledge of his profession, he brought to its application in actual life that happy combination of scientific and practical acumen, conjoined with a peculiar charm of manner, which make the physician in the truest and best sense of the word. Prompted by a thorough love of medicine, he laboured closely and hard at some of its most complicated problems, and he has left results of enduring value both scientific and practical. His scientific work is characterised by keen insight into the problems with which he dealt, and by a rare appreciation of the light in which his researches should be regarded, as contributing, on the one hand, to existing knowledge of the subjects to which they referred, and, on the other, to the furtherance of investigation. His practical work was distinguished by the skill with which he sought to deduce principles of treatment from pathological and physiological data, and rationalised necessary empiricisms. Widely read in the literature of his profession, he brought a richly stored memory to his editorial and literary duties. He was an eager upholder of the dignity of medicine, and an unsparing critic of whatever militated against the good name of the profession within or without its ranks. A clear and incisive style gave power to a pen which, if it were keen, was never unkind, and which has performed an active and influential part in all the great questions which have agitated medicine in its social and political bearings for some years past.

"The substantial fruits of Dr. Anstie's labours were about to be gathered when, in the earnest pursuit of a duty, he accidentally received the infection which killed him. Medicine, although rich in sterling workers, can ill afford to lose such a man, and the manner of his death aggravates the painful sense of his loss. It was too costly a life to have been sacrificed prematurely in so pitiful a way."

## NOTICES TO CORRESPONDENTS.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

## PRIVATE TEACHING IN STEEVENS' HOSPITAL, DUBLIN.

WE learn with regret that the information upon this subject published in our Students' Number was in some respects inaccurate. Dr. Tweedy is erroneously stated to undertake the preparation of pupils for the preliminary examinations of the College of Surgeons, and the name of Dr. Warren is omitted as teaching chemistry, materia medica, and botany. We the more regret the inadvertent insertion of a paragraph taken from last year's Students' Number, because, in respect to Dr. Tweedy, a similar erroneous opinion has prevailed in other quarters.

Dr. Tweedy is now an Examiner in General Education in the College of Surgeons, with which position private teaching would be obviously inconsistent. Dr. Warren is the recognised teacher of pharmaceutical subjects in Steevens' Hospital.

## UNIQUE OPHTHALMIC DISEASE (W. H. S.).—Declined with thanks.

DUREAM.—The dates of examinations in the Queen's University for the coming year are not yet accurately fixed.

L. M. (Hibernian Hotel).—Any recognised medical and surgical diplomas, with a diploma in midwifery, are sufficient qualifications to hold a workhouse hospital appointment.

Dr. K.—Space permitting, in our next. Thanks.

AMERICAN SUROCKY AND FEES.—A paragraph is just now going the round of the English laypapers to the effect that "a fee of 150,000 dollars (about £30,000) has been received by an American surgeon for removing a wen. The operation was performed with electric knives." Our readers will perhaps pardon us for not committing ourselves to an opinion on the subject; we have not yet been able to make up our minds as to which is the more wonderful—the fee or the operation.

## A MEDICAL ALLIANCE.

In our issue of the 9th inst. we drew attention to an announcement which proposed to establish "A Medical Alliance," for the purpose of mutual protection and defence in cases of false accusation and extortion, to which members of our profession are peculiarly liable. Before giving such a movement our support, we asked that the members of the committee and the hon. secretary should furnish their names as a guarantee of its genuineness, and a proof that the remedy is not worse than the disease. In reply thereto we have received a preliminary prospectus, together with a letter signed J. B. Budgett, M.D., Hon. Sec., in which it is proposed to convene a public meeting of the profession on the subject a few days hence, the temporary offices of the society being 66 Ludgate Hill, London. Upon reference to the *Medical Register* of this year the name of J. B. Budgett, M.D., does not appear. Perhaps Dr. (?) Budgett can inform us the reason of such omission.

## THE SEWAGE QUESTION.

A CORRESPONDENT sends us a long letter upon this subject but as it has already been so fully and ably discussed in our columns in Dr. Letheby's "Notes and Analyses" we can only give a few excerpts.

Speaking of sewage farming, he remarks that "experiments may do in outlandish places, but let them be adopted in the neighbourhood of towns, exposed to the rays of the sun, the decomposition will produce a malaria which, wafted by the wind, will carry the spectral gloom—cholera, typhus, scarlet, and other fevers, small-pox, diphtheria, dysentery, and allied disorders—among the neighbouring residents, ready to pounce upon every one, weak or strong, according to constitution, &c., and with fatal effect. Therefore, let such parties beware, or they may breed a plague in the land, and be guilty of wholesale manslaughter among young and old before they are aware of it. Serious as this may appear, it is nothing but the truth, and must be avoided, as, if extensively used in such a form these results are sure to follow. It may be argued that the earth is a great disinfectant in itself. Granted; but to be available for such a purpose the sewage would have to be constantly ploughed in and mixed with it, a thing impossible during the growth of crops."

ERRATA.—"Medical Science and Medical Teaching."—Mr. Barraclough, the author of these papers, which have recently appeared in our columns, wishes to correct one or two errors which occurred through his unexpected absence from town when the proofs were sent him. Page 106, for "impressed" read "expressed;" page 131, for "abusive" read "obtrusive;" page 178, for "exercising" read "exorcising."

COMMUNICATIONS, Enclosures, &c., have been received from Mr. Arthur Jackson, Sheffield. Dr. Haldane, Edinburgh. Dr. Delvalle, Paris. Dr. McCall Anderson, Glasgow. Dr. Habershon, London. Mr. W. Allingham, London. Dr. Burness, London. Dr. Duncan, Glasgow. Mr. Stocker, Guy's Hospital. Mr. G. Cowell, London. Dr. Muter, London. Dr. Langley, London. Dr. Fitt, Bath. Mr. Alexander, Hammermith. Dr. Budgett, Eastbourne. Dr. Rogers, London. Mr. Barraclough, Kennington. Mr. Hogg, London. Dr. Lombard, Leamington. Dr. J. P. White, Albany, U.S.A. Dr. Fennelather, Tipperary. Dr. Morell Mackenzie, London. Mr. Gaskoin, London. Dr. King, London. Dr. Kent Spender, Bath. Mr. Adams Parker, Birmingham. Mr. Whitford, London. Mr. Henry Dobbin, Brompton. Mr. Mills, Bourne. Mr. Barclay, Birmingham. Mr. Faulkner, St. John's Wood. Mr. Black, Edinburgh. Mr. Clowes, Norwich. Dr. Marshall Lamberhurst. Dr. Morgan, Dublin. Dr. J. Farrish, Baltimore. Mr. Furneaux Jordan, Birmingham. Dr. Cameron, Dublin. Dr. Quain, London. Dr. Balhazar Foster, Birmingham. Mr. Miller, Wrentham. Dr. Leadman, Leeds. Mr. Clifton, Fordingbridge. Dr. Donkin, Paris. Mr. Baker, London. Dr. Cesar, Shizley. Dr. Dawes, Dresden. Dr. Eddison, Leeds. Mr. Keith, Edinburgh. Dr. Howes, Dunlain. Dr. Milner Fothergill, London. Mr. Dickinson, Brighton. Mr. Hird, Charing Cross Hospital. Dr. Binder, Bristol. Dr. James, Spa. Dr. Drysdale, Folkestone. Dr. Green, Peckham. Dr. Higginson, Donaghadee. Mr. Grace, Bristol. Dr. Kennedy, Dublin. Dr. Davys, Swords. Mr. John Cooke, Thurles. Mr. Thomson, Alfordie, &c., &c.

## BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

An Introduction to Pharmaceutical and Medical Chemistry. By John Muter, M.D., M.A., &c.

How to Restore Muscular Movement Generally. By F. G. Bennett, M.R.C.S. London: Whittaker and Co.

Free Phosphorus in Medicine. By J. A. Thompson, M.R.C.S. London: H. K. Lewis.

A Treatise on the Relief and Cure of Spinal Curvatures, &c. By F. G. Bennett, M.R.C.S., L.S.A.

## VACANCIES.

University College, London. Professorship of Comparative Anatomy and Zoology. Full information of Mr. Robson, at the College.  
Metropolitan Free Hospital. Assistant House Surgeon. No salary.  
St. Marylebone, London. Medical Officer for the Christ Church District. Salary, £230 per annum. Application to be made to the Clerk, at the Union Office.

Queen's Hospital, Birmingham. House Surgeonships. Salary, £50 per annum, with board and residence. Address the Secretary.  
Bedford General Infirmary. House Surgeon. Salary, £100 per annum, with board and residence. Testimonials to the Chairman of Committee.

Three Counties Pauper Lunatic Asylum. Resident Medical Superintendent. Salary, £800, with furnished house. Applications to the Clerk of Committee, St. Neots, Hunts.

Lutterworth Union. Medical Officer. Salary, £104 per annum for the District, and £30 for the Workhouse. Apply to the Clerk of the Union.

Ripon Dispensary. Resident Medical Officer. Salary, £100 per annum. Full particulars of the Hon. Sec.

Liverpool Dispensary. Assistant House Surgeon. Commanding salary at £108 per annum, with apartment's. Address the Secretary.

St. Mary's Hospital, Manchester. Medical Officer. Salary, £80 per annum, with board and residence. Applications to the Secretary.

Royal Albert Hospital, Devonport. Junior Surgeon. Honorary.

Kent. Public Analyst. Remuneration by fees. Address the Clerk of the Peace, Maidstone.

## APPOINTMENTS.

BRANWELL, B., M.D. Ed., Physician to the Newcastle-on-Tyne Infirmary.

CATTELL-JONES, T., M.R.C.S.E., Medical Officer for the newly-formed Spepperton District of the Staines Union.

CLARKSON, J. W., M.R.C.S.E., L.R.C.P.L., House Physician to St. Thomas's Hospital.

DAVIES, H. W., M.R.C.S.E., Resident House Surgeon and Registrar to the Cancer Hospital, Brompton.

DEARLEY, H. H., M.R.C.S.E., L.S.A.L., Medical Officer for the Hoxne District of the Hoxne Union, Suffolk.

GAMER, J. E., M.B., C.M., Senior House Surgeon to the Preston and County of Lancaster Royal Infirmary and Dispensary.

GENOVELL, S., M.B. Univ. Glas., Assistant to the Professor of Medicine at the University of Glasgow.

GUTHRIE, G., M.B., C.M. Ed., Assistant Medical Officer to the County Asylum, Burntwood, Litchfield.

HEWARD, J. M., M.R.C.S., L.S.A., Medical Officer to the Stamford Urban Sanitary District.

IRVING, C., M.R.C.S.E., House Surgeon to the Great Northern Hospital.

MAUNSELL, J., M.D., Qu. Univ. Irel., L.R.C.S. Ed., Assistant House Surgeon to the Liverpool East Dispensary.

MAVOE, W. E., M.R.C.S.E., L.R.C.P.L., House Physician to St. Thomas's Hospital.

SCHOLER, R. S., M.B., C.M. Ed., Assistant House Surgeon to the Stockport Infirmary.

SMITH, W., L.R.C.P. Ed., Junior House Surgeon to the Preston and County of Lancaster Royal Infirmary and Dispensary.

WILSON, H. C., M.D. Qu. Univ. Irel., an additional Resident Surgeon at the Birmingham General Dispensary.

## Births.

CULHANE.—At Killelane Cottage, Newcastle West, the wife of Patrick Culhane, M.D., of a son.

HIGGINSON.—On the 9th inst., at Donaghadee, co. Down, the wife of H. Talbot Higginson, M.D., L.R.C.S., of a son.

KING.—On the 14th inst., in Harley Street, London, the wife of Dr. Robt. King, of a son.

## Marriages.

EDIE—MURRAY.—On the 9th inst., at Belmont Street, Aberdeen, Arthur Wellesley Edie, M.D., of Wimpole Street, Cavendish Square, London, to Mary, youngest daughter of Andrew Murray, Esq.

MESSER—MAY.—On the 15th inst., at the Church of St. James the Great, Devonport, John Cockburn Messer, M.D., Staff-Surgeon R.N., H.M.S. *Implacable*, to Elizabeth, eldest daughter of Joseph May, F.R.C.S., J.P. of Devonport.

SMITH—DOWSON.—On the 10th inst., at St. Paul's Church, Clifton, Bristol, R. Shingleton Smith, M.D., of Rokeby House, Clifton, to Elise, only daughter of the late H. Cox Dowson, Esq., of Bayonne.

TOMLINS—EVETT.—On the 20th inst., at St. Michael's, Handsworth, James Tomlins, M.R.C.S.E., L.R.C.P. Ed., Newport, Shropshire, to Julia, youngest daughter of James Evett, Esq., of Handsworth.

## Deaths.

CARTER.—On the 14th September, at Wimpole Street, in his 11th year, after a lingering illness, Arthur Septimus Becher, the beloved son of Robert Brudenell Carter, F.R.C.S.

CASS.—On the 2nd September, Edward E. Cass, M.R.C.S. Eng., L.S.A. Lond., of Gooles, aged 31.

GORDON.—On the 8th September, at Heath Cottage, Charlestown, Aberlour, George Gordon, L.R.C.S. Edin., Surgeon R.N.

HIGGINSON.—On the 10th September, at Donaghadee, the infant son of H. Talbot Higginson, M.D., L.R.C.S.I.

KING.—On the 12th September, Daniel King, M.R.C.S. Eng., of Bideford, aged 28.

MURRAY.—On the 16th September, at Wickham, Hants, John Murray, M.A., M.D.

PAXTON.—On the 10th August, on the homeward voyage from the Cape, William Albert Paxton, M.B., surgeon steamship *Adriatic*.

SOMERVILLE.—On the 12th September, Samuel Somerville, M.D., of Hart Street, Edinburgh.

## MIDDLESEX HOSPITAL COLLEGE DINNER.

The ANNUAL DINNER of the past and present Students of the Hospital and their friends will take place in the usual room at St. James's Hall on October 1st, at 6.30 p.m., JOHN TOMES, Esq., F.R.S., in the Chair. The cost of the Dinner will be 7s. 6d., exclusive of wine. Gentlemen intending to be present are requested to communicate with the Dean on or before September 30th.

ROBERT KING, B.A., M.B., Dean.

## ST. MARY'S HOSPITAL MEDICAL SCHOOL.

Opening of WINTER SESSION, October 1st, 1874. Introductory Address by Mr. EDWARD OWEN.—For further particulars apply to the Registrar at the Hospital, or to

A. B. SHEPHERD, M.B., Dean of the School.

## ST. MARY'S MEDICAL SCHOOL.—Three OPEN

SCHOLARSHIPS and TWO EXHIBITIONS, October, 1874.—For particulars apply to the Dean, St. Mary's Hospital, Paddington, W.

## UNIVERSITY OF LONDON.—MATRICULATION and

PRELIMINARY SCIENTIFIC EXAMINATIONS. SPECIAL CLASSES for these Examinations are held at ST. BARTHOLOMEW'S HOSPITAL. The Classes are not confined to Students of the Hospital.

A Class for the Matriculation Examination is held twice in each year, from October to January, and from March to June.

A Class for the Preliminary Scientific Examination is held from January to July.

For particulars, application may be made personally or by letter to the Warden of the College, St. Bartholomew's Hospital.

## ST. BARTHOLOMEW'S HOSPITAL and COLLEGE.

SCHOLARSHIP in SCIENCE. Two Scholarships in Science have been founded at St. Bartholomew's Hospital. 1. An Open Scholarship of the value of £100, tenable for one year, to be competed for in September. The subjects of examination are—Physics, Chemistry, Botany, and Zoology. The successful candidate will be required to enter at St. Bartholomew's Hospital in October next. 2. Preliminary Scientific Scholarship of the value of £50, tenable for one year, to be competed for in October next by Students of the Hospital of less than six months' standing. The subjects of examination are identical with those of the Open Scholarship. For further particulars and syllabus of subjects, application may be made, personally or by letter, to the Warden of the College, St. Bartholomew's Hospital.

## ST. BARTHOLOMEW'S HOSPITAL and COLLEGE.

The WINTER SESSION will begin on THURSDAY, October 1st. The Clinical Practice of the Hospital comprises a service of 710 Beds, inclusive of thirty-four Beds for Convalescents at Highgate.

Students can reside within the Hospital walls, subject to the College regulations.

For all particulars concerning either the Hospital or College, application may be made, personally or by letter, to the Resident Warden of the College.

A Handbook will be forwarded on application.

## THE LONDON HOSPITAL and MEDICAL COLLEGE.

The next WINTER SESSION will commence on Thursday, October 1st, 1874, when the Introductory Lectures will be given at 3 p.m. by SAMUEL FENWICK, M.D., Assistant-Physician to the Hospital.

General Fee to Lectures and Hospital Practice, 90 guineas, payable in two instalments of 45 guineas each. Library Fee, £1 1s. Special entries can be made to Lectures or Practice.

The Hospital contains 600 beds. The In-patients during 1873 were 5,613, and the Out-patients 45,908; total, 49,421.

The Following Prizes and Appointments are offered, without any further payment, to Students paying the general fee of 90 guineas:—

Seven Scholarships to be offered for competition in the Winter Session:

1. A Scholarship of £30 to the Student of less than three months' standing who passes in October the best examination in the subjects required at the Preliminary Examination.
2. A Scholarship of £30 to the Student of less than three months' standing placed second in the above examination.
3. A Scholarship of £30 in Human Anatomy for first year Students; to be awarded in April, 1875.
4. A Hospital Scholarship, value £25, in Anatomy, Physiology, and Chemistry, for first year and second year Students; to be awarded in April, 1875.
5. A Hospital Scholarship, value £30, for Clinical Medicine; to be awarded in April, 1875.
6. A Hospital Scholarship, value £30, for Clinical Surgery; to be awarded in April, 1875.
7. A Hospital Scholarship, value £30, for Clinical Obstetrics; to be awarded in April, 1875; and a Prize of £5 to the Student who has attended most Midwifery cases for the Hospital during the preceding twelve months.

The Duckworth Nelson Prize, value £10, for Practical Medicine and Surgery (Biennial), 1875.

Money Prizes to the value of £80 given annually by the House Committee for zeal in Dressing Out-patients and knowledge of Minor Surgery.

For particulars as to appointments, &c., see the Prospectus, which will be forwarded on application to the Bedell of the London Hospital Medical College, Turner Street, E.

Further information may also be obtained from Mr. JAMES E. ADAMS, Treasurer, 10 Finsbury Circus, E.C.; or Mr. WARREN TAY, Vice-Dean, at the Medical College.

the mechanical method *in toto*, he would likely say mechanical instruments are worse than useless, and not to attempt to use them. Then comes the question, who are you to mind, for we have two diametrically opposed to each other; one would appear to be right and the other wrong. In my opinion they are both wrong, and to do any good I have found a medium course will frequently work out the happiest results. All plans no doubt have certain advantages, and occasionally one case will be benefited more by one line of treatment than another.

If this curvature arises early in life, and occurs in a debilitated scrofulous subject, good tonics and a generous diet should be ordered. Sea-bathing gives great tone to debilitated muscles. An instrument or mechanical appliance in a weakly-developed child, whose muscles are flaccid, is certainly contra-indicated, as the compression and weight of an instrument only limits and prevents healthy development and muscular action; but in the curvature produced by rickets, mollities ossium, or when the curvature has reached its most aggravated form, a well-fitting appliance is frequently of great use, and gives good support. The recumbent and lying position in some cases should be enforced, but to give any more than a brief outline of the treatment would be useless, for every case requires frequently a variety of methods and plans of treatment to correct the existing and prevent a further increase of the

FIG. 15.

A Simple and most Useful Mechanical Spinal Support.

deformity. Fig. 15 is an appliance that frequently is of use in the treatment, and on examining this minutely it will give an idea of the principle of all spinal and mechanical supports—viz., a pelvic band, to which is attached upright stems, ending, in some cases, like crutch-handles, and on which are attached steel padded plates and bands to press on the projecting portions, and gives general and local support in the different situations requiring it.

Fig. 16 also represents a spinal corset, made with vulcanised india-rubber bands.

#### ANTERIOR CURVATURE OF THE SPINE.

**Definition and Anatomical Characteristics.**—This distortion is by no means so common as the last-mentioned. The curvature takes place principally in the lumbar region, and the physiological lumbar curve is greatly increased, with a convexity in the forward direction, and the person thus affected walks with a most unsteady gait. Women seem to be more often affected than men; in fact, this holds good with all the spinal curvatures. As I said before, this occurs in the lumbar region, and after a time is a predisposing cause to distortion in the other regions.

**Causes.**—Disease, debility, calling or trade, carrying heavy weights on the head. Rickets is a most common cause. It is sometimes said to be congenital, as it is sometimes seen in connection with spina bifida. Obliquity of

the pelvis or one leg shorter than the other are said to be causes.

**Treatment.**—Much will depend on the cause, whether of debility or actual disease. The recumbent position—"laid on the broad of the back," as the saying is—is by no

FIG. 16.

A Spinal Corset, with Vulcanised India-Rubber Bands.

means a bad method, for we know that on assuming the lying posture we more or less decrease or obliterate the curve altogether. The "recumbent position" for a continued time is no doubt, if the health will allow of it, the proper and most useful line of treatment, and most likely to do more good than anything else. Spinal supports are recommended; but I do not think much advantage is gained by their use.

#### LATERAL CURVATURES OF THE SPINE.

**Definition and Anatomical Characters.**—This, of all curvatures of the spine, is the most important, as it is perhaps more frequently met with than any other. It consists in a deviation of the spinal column in a lateral direction in the form of curves, which are termed, as they occur in order, primary and secondary, which must arise, as a matter of course, to preserve equilibrium when the body is in the erect position. With this curvature there is always associated more or less horizontal rotation of the individual vertebrae in the situation of the curve, which varies as they are removed from the centre of the primary curve. The rotation occasionally increases to a considerable extent, so that the anterior portion of the bodies rotate in the direction of the curve, until they are opposite to the natural position of the transverse processes; and, in like manner, the spinous processes partake of a rotation in the same way, until they are opposite to the natural position of the transverse processes on the opposite side. Many causes have been assigned for this rotation by different authors; but it seems to me that it is a natural consequence of the abnormal curve to preserve equilibrium,

acted on by the various muscles having attachment to the spine or to the ribs, which anatomically have a twofold attachment to the vertebrae, and muscles inserted into or arising from, may be said to exert considerable power on the spinal column, although in an indirect manner. Anyone conversant with the muscular system in the back, with a little consideration, can easily understand in what manner the action of one set of muscles will facilitate by their

FIG. 17.

Spinal Mechanical Support.

action the production of abnormal curves, and he will also see that the action of muscles on both sides act in such a beautiful and harmonious way as to keep the healthy spinal column in a perfect manner, so as to preserve its natural curves for the purpose of equilibrium, now knowing the muscles act on each side in perfect harmonious antagonism in a healthy, strong, robust subject. On the other hand, take, for example, the case of a weak, delicate, scrofulous, rickety subject, who leads a sedentary life, compelled to remain in a habitual oblique position in a factory, workshop, or over a sewing machine; add to that slight paralysis of the muscles on one side, induced by the position, and you have at once, without looking for other difficulties, or endeavouring to propound far-fetched and unpractical theories, the common-sense and every-day occurrence of the way such curvatures are produced.

**Causes.**—These may be divided into the predisposing and exciting. 1. Predisposing disease, such as scrofula, rickets, which I may mention most frequently, gives rise to curvature of the spine. Mollities ossium also more or less predisposes, caused by accident, disease, one leg shorter than the other; this is ascribed by authors on the subject as a most common cause—a fact which I may mention my experience is also in unison with. The habit that some people fall into unconsciously of resting on one leg when they stand for any time has also been ascribed as a most frequent cause; but it must be understood that the simple standing in such position by a healthy person is not at all likely to be followed by any bad consequences; but the weak and delicate, particularly girls between the ages of 11 and 17, stand in such a position designedly for the purpose of endeavouring to remove the lassitude and weakness they experience in their backs and loins. Such a practice, by repeated acts, develops a habit which, in due course, causes the spine to acquire a certain "set." The bony column being distorted, the action of all the muscles inserted into it are more or less disarranged, and act in a very irregular manner, and do not antagonise each other at all, and in many cases facilitate by this irregular action the production of an abnormal curve if not developed already; and considerably increasing it if primarily produced, and by degrees the whole trunk, as a secondary consequence, assumes a most deformed, unsightly-looking appearance, the thorax becomes considerably drawn to the affected side, respiration is occasionally very much impeded, the ribs are separated and drawn backwards and upwards.

Sex has a great deal to say in influencing this deformity. It is nearly always seen in girls. To see it in boys is most uncommon. Delicate girls belonging to the scrofulous diathesis, generally before or about the commencement of the menstrual period, is the most common time to see symptoms of incipient curvature beginning.

2. **Exciting Causes.**—A trade or calling that compels the person so following it to lead a very sedentary life, and also when working to place the spine and trunk in an oblique and trying posture, want of healthy out-door exercise. Those females who habitually over-indulge in horse exercise, for it only requires a moment's consideration to understand the very distorted state the spine must assume to maintain equilibrium in the sitting posture when the female form rests on the lady's side-saddle, this has, in very delicate females, been a most exciting cause in producing such lateral curvatures. In my saying this, I trust, however, I may not be understood to depreciate in the slightest degree such healthy exercise, for of all others I consider none more useful and enjoyable, and in moderation nothing tends more to brace up and enliven delicate constitutions; but its *abuse* and not its *use* I would warn you against.

**Signs and Symptoms.**—When lateral curvature has existed for any time it is most obvious. On inspection the spinal column can easily be seen to be bent to one side or the other, with a slightly apparent appearance of the formation of a secondary curve. The side most affected is the right, which frequency has been ascribed to people using their right hand and arm more than the left. However, the deformity in the incipient stage is more obscure, and the signs appear occasionally in a very slow and gradual manner. If the right side is affected the right shoulder appears, on minute examination, considerably elevated, and is what is termed "growing out," whereas the left is, at the same time, materially depressed and flattened. A very fair way of judging is with a pen and ink, or red chalk, to begin from the spine of the first dorsal to the last lumbar, and draw a line passing through each spine between those points, and if there is any perceptible change it will be easily observed at a glance by the direction of this line. As the distortion advances, horizontal rotation of the bodies of the vertebrae takes place and renders the deformity quite palpable; the body also acts secondary to the spine in appearing to move in an upward direction, and rendering the scapula and thorax elevated and raised on the affected side, leaving the lateral aspect of the ribs and thorax on the non-affected side quite hollow and sunken. Respiration, owing to the change in the thoracic cavity, becomes, after a time, considerably impeded, as all the viscera and large arteries in the thorax are more or less displaced in order to accommodate themselves to their new distorted position the pelvis also becomes oblique, and partakes in a secondary manner the effect of the primary displacement, and this obliquity renders the passing of catheters in the male, or performing any midwifery or obstetric manipulation in the female a matter of considerable difficulty. Curvature in the incipient stage generally disappears when the person is placed in the recumbent position. After a time well-marked symptoms of cachexia and anemia set in, the skin is pallid and unhealthy-looking, there is a weakness and lassitude always complained of in the loins and back, attended with loss of appetite, muscular emaciation, and general symptoms of debility.

(To be continued.)

## REPORT ON SYPHILIS.

By C. R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.,  
Senior Physician to the Metropolitan Free Hospital.

DR. FOURNIER'S LECTURES (continued).

Quite on the contrary with tertiary syphilitic affections—there is none in the enormous majority of cases, as

we have previously established. In some very rare circumstances only, and these rare enough to be qualified as exceptional, the ulcerations awaken but little glandular affection, when they result either from tertiary gummy infiltration or from an inflammatory or strumous complication. But, in these same cases, that which is produced is an affection of the glands of another kind, the characters of which I will describe to you in detail apropos of tertiary gland affections. This adenopathy is different from that of the chancre; it presents generally neither the indolence, the hardness, nor the multiplicity of this. Thus, putting aside exceptional cases, and concerning ourselves merely with cases often seen, the diagnosis may be established generally on consideration of the glands, and is summoned up thus: with the chancre, characteristic glandular affection; with the tertiary syphilitic affection, no adenopathy.

2. *Concomitant Manifestations.*—This consideration may be significative, and very much so. But if, for instance, there is produced simultaneously with the syphilitic appearance resembling chancre another clearly syphilitic manifestation, and tertiary in character (such, for instance, as ulceration of the pharynx), it is clearly only a consecutive manifestation, a tertiary symptom; for common observation shows it, and with the unanimous admission of all writers on syphilis, we never see at once appear on the same person a hard chancre and a lesion of tertiary character. That is not found in nature, and does not exist. This consideration alone clears up the diagnosis in certain cases.

For instance, a patient was affected for a fortnight past with a chancre like ulceration of the glando-preputial space. The lesion was circumscribed, indurated, and recalled exactly the classical character of the chancre. Anyone might have been deceived by it. But, in addition, the patient had at the same time been affected with a gummy syphilitic tumour on the back and on the tongue. The sole fact of this appearance at the same time of manifestly tertiary symptoms on the back and tongue clearly established that the gland lesion was of the same form, that is, a tertiary syphilitic symptom like a chancre.

Unfortunately, this recourse to concomitant accidents is not always possible; then there is nothing to be gained by this symptom.

3. *Ultior Evolution.*—The ultior evolution has no less value in determining the nature of the accidents; it is in some way the criterium of them. After a chancre there is shortly an explosion of what is called the secondary series, that is, multiple, disseminated manifestations, spread over the patient, and of well-known aspect. After the tertiary chancriform symptom there is either absence of all symptoms or tertiary accidents in other places.

Such is the *résumé* of the elements on which we may establish the diagnosis of tertiary symptoms and indurated chancre. Well, gentlemen, do not be deceived in this, that is an important part of diagnosis, essential in two ways, as you are about to see.

In the matter of practice, firstly, the error which consists in mistaking an ulcerated chancriform tertiary symptom for a chancre makes us commence a treatment which is that of the diathesis when it is born, and not that of the tertiary stage.

In the matter of doctrine, in the second place, the same error conducts to this: a new contagion of syphilis on a syphilitic field, a syphilis added to a former syphilis, that is to say, double syphilis. Now, this error is committed, and that not unfrequently. More than once practitioners have taken for indurated chancres relapses of secondary or tertiary syphilitic affections, indurated tertiary affections of chancre form, and have hence concluded that syphilis can be renewed at short intervals, or even be tripled on the same subject, whilst in reality the cases of syphilitic reinfection remain in the condition of facts rigorously possible, but absolutely exceptional.

Analyse the few cases (cases too rare, alas! showing the extinction of syphilis; it were to be desired they were more numerous), examine, I say, the few cases of double

syphilis which have been published by various authors, and you will remain convinced, after minute examination, that several of these pretended relapsing chancres were nothing more than indurated syphilitic symptoms. Many, indeed, by their own symptoms, and their general evolution, by the affection of the glands and ulterior accidents, exactly answer to the indurated syphilitic affections which I have just spoken about. Besides, we do not see in the description of cases to which I allude that anyone has occupied himself in establishing a differential diagnosis between the pretended chancre and the indurated syphilitic symptoms which might have been like it. That at least is a desideratum which makes these observations more than suspicious, and which takes from them all or part of the meaning which their authors have attached to them.

From what we now know, from what we know of tertiary indurations, it should now no longer suffice to recognise on a syphilitic patient a lesion isolated, circumscribed, hard, and chancre-like, as resulting from a fresh contagion. Certainly this lesion may be a chancre, and I see no obstacle to this; I raise no *a priori* objection against it. But it may also be that this lesion may not be a chancre, that it may have merely the look of a chancre, its mark and general appearance; it may be, in short, that it is but a chancre-like syphilitic symptom, or pseudo-chancre. The knowledge of the pseudo-chancre, then, introduces an element of a new kind into the question of double syphilis. And this element is the diagnosis of the true indurated sore, and of the syphilitic symptoms which may simulate it. Nevertheless, gentlemen, do not conclude from this that from prejudice I refuse the possibility of syphilitic reinfections. I should have expressed myself ill if I left you with this idea. I do not say that syphilis may not double itself. Far from that. I believe in the possible relapse of the disease, and I demand with all my heart facts proper to demonstrate this double relapse; only I ask for demonstrative and probative facts. When observations of this kind present themselves I submit them to a severe analysis, for to be accepted they ought to rest on a collection of irrefutable proofs. It is because I would desire these observations to be as demonstrative as possible that I wish to tell you what they ought to be so as to be beyond criticism. And it is in this view that in what now concerns us I have tried to establish, that the pseudo-chancre, unrecognised in its species as an accident, may resemble a true chancre and resemble a second infection.

3. A third lesion, which we ought to place on a parallel with tertiary syphilitic affections, when ulcerating, is the *cancroid*. The *cancroid*, in its ulcerative periods, may, in the male especially, simulate tertiary lesions. Needless to say what interest there is in distinguishing them. Error, indeed, in such cases conducts either to a grave operation, a very grave one, from the mutilation which ensues, and an operation, the more to be regretted because it might have been supplied, and well supplied, by the administration of specific treatment, or leads to an expectation not less dangerous; or, again, to antervention of specific treatment, having the grave evil of deferring a necessary operation and rendering the operation later inaccessible to surgical methods.

The errors committed in such cases are pretty frequent, and that for a very simple reason, that is, because cancer and tertiary genital affections are rather rare affections, little described, some varieties of which have not yet found a home among our classics. I hear from M. Ricord that he has had several times to suspend and to prevent operations which had been proposed for pretended cancer of the penis, which were nothing but simple syphilitic affections, and were quickly cured by specific treatment.

And what operation had been proposed in the cases observed by M. Ricord? Amputation of a part of the penis, or even of the whole penis. Thrice, for my part, I have been fortunate enough to cure in this way lesions of the penis which had been diagnosed cancerous, and for which the probable necessity of an operation had been thought of.

Such was the case, for instance, of a young foreign officer, to whom the doctors across the Rhine had proposed the amputation of the penis for a very curious lesion of the meatus, reputed cancerous, and being in reality only syphilitic. This lesion, which was eight or ten months old when I saw it for the first time, had hollowed out the meatus so as to dig in the top of the gland a kind of funnel at least one and a half centimetres deep. Round this the infiltrated walls of the gland were hard, and of a dark red, almost violet in hue. Submitted to specific treatment, with simple dressings, with iodine ointment, this young man was cured very well without operation, but, of course, with a persistent deformity. By what signs, then, shall we differentiate the ulcerated cancrroid from tertiary ulcers? Several orders of considerations may serve this diagnosis:—

1. *Commemoratives.*—With the cancrroid, save by coincidence, there is absence of anterior syphilitic affections; with tertiary syphilitic affections or anterior accidents.

2. *Mode of Evolution.*—With the cancrroid, evolution is much slower in kind, and the ulceration is preceded by a rather long period, during which the lesion shows itself in the state of a dry tumour, hard and not ulcerated. For several months, sometimes for a year and more, the cancer remains, or may remain, in the mushroom state, or tuberoso tumour, vegetating with dry surface, non-ulcerated. There is nothing like this in tertiary syphilitic affections, which either ulcerate at once, originally (ulcerated form), or develop infiltrations (gummy form) which ulcerate in a relatively very rapid way.

3. In the condition of ulcer, the cancer is an *ulcerated tumour*. Even in its gnawing and excavating form, there is still a base which points it out as a tumour, and of this the hardness, dryness, and elasticity show that the ulcer is formed on a morbid tissue which is destroyed. Tertiary syphilitic affections, on the other hand, are ulcers without true tumour. At the most they are ulcers with hard base, engorged and infiltrated; but the base does not give, or gives less than the cancer, the sensation of a tumour beneath the ulceration. It has not in any case the hardness of the cancer.

4. *Objective Symptoms of the Ulceration.*—The ulceration of the cancer is redder, and more fungous than that of tertiary ulcers; it bleeds more easily; secretes an ichorous sanies more diffuent, more foetid. It is often surrounded, and bordered by mammillary vegetations, like raspberries, or cauliflowers, &c.

5. *State of the Glands.*—At a certain time the cancer has an almost certain influence on the glands, which become hard, voluminous, and may even ulcerate, bud forth, and vegetate. With syphilitic affections there is no affection of the glands, at least, in the enormous majority of cases, and with the exception of inflammatory and strumous complications.

6. *Action of the Specific Treatment.*—Whilst the specific treatment remains without any action on the cancer, it is rapidly active in tertiary symptoms. It is then, here, as in so many other cases that I have spoken of, to specific treatment that we should have recourse when the least doubt subsists as to the nature of the lesion; it is this which it is urgent and imperative to consult as a diagnostic criterion to guard against those operations so eminently regrettable, of which several examples, I repeat, have been met with.

## In Memoriam.

ARTHUR JACOB is dead! The simple announcement of this fact must be sufficient to excite in the minds of the older members of our profession, and more especially so in the minds of those who knew him, many memories, and even by the younger members, who could only have known of him by his remarkable contributions to medical literature, the announcement will not be received un-

moved that the illustrious discoverer of the "Membrana Jacobi" is now no more. To attempt to describe the feelings of the proprietor of this journal, or of all those so long and so intimately associated with the late Dr. Jacob in its working, the writer of these few lines feels would but be to tread on sacred ground, a desecration from which he shrinks, preferring instead, by a brief notice of the life of an earnest, honest, and pre-eminently intellectual man, to stimulate, so far as his feeble pen will permit, those who come after him to "go and do likewise."

Born on the 13th June, 1790, at Knockfin, near Maryboro, in the Queen's County, Arthur Jacob seems to have had hereditary claims on our profession, for his father was John Jacob, for many years surgeon to the Queen's County Infirmary, who commanded a leading practice in the midland counties, and of whose energy and skill many stories are even still told; and his grandfather was Michael Jacob, a surgeon in very extensive practice in Ballinakill, in the same county. Dr. Jacob was the direct lineal descendant and senior representative of an old English family who resided in Kent in the 13th century, and subsequently held estates at Gamlingay, in Cambridgeshire, in the reign of Henry VIII. To one of this family, Sir John Jacob, of Bromley, in Middlesex, a baronetcy was granted by Charles II., in consideration of his great services to the cause of the martyred king, which title passed through five generations, when it became extinct by the death of Sir Clement Brydges Jacob, in the latter part of the last century. The third baronet of the name served as Colonel of Foot at the Boyne and Aughrim, and for military services about the same period a cousin of his received an extensive grant of land at Sigginstown, near Wexford, under the Act of Settlement in 1667, and became the founder of the Irish branch of the family of Jacob, the junior offshoot of which remained as colonists of the County of Wexford, and the senior established itself in the Queen's County, where it has held a high position for more than a century and a half. Of this, which happens by the extinction of the direct line of the Cambridgeshire family—to be the direct lineal descendants of the Kentish residents, Dr. Arthur Jacob was the senior representative.

Having received a sound preliminary education, he commenced at an early age the study of his profession under the personal supervision of his father, and after a few years so spent he proceeded to Dublin, carrying with him letters of introduction to Abraham Colles, then a leading surgeon attached to Steevens' Hospital, within the walls of which institution he served his time, and on the completion of his studies, graduated as M.D. in the University of Edinburgh in the year 1814. The energy of his character and the vigour of his constitution may be inferred from the fact that after his graduation in Edinburgh he started on foot through Scotland, Wales, and England, visiting the principal towns on his route, and closely inspecting their medical institutions; and it was in subsequent years a source of pride with him to be able to state that during the six weeks so occupied he traversed 960 miles. Arriving in London, he again started on foot, but this time directing his steps to Dover, whence he crossed over to Boulogne, and, again on foot, proceeded to Paris, where he spent some months, eagerly availing himself of the opportunities for improving himself afforded by the hospitals in that city. The news of the 1st March, 1815, however, startled him from the pursuit of his studies, as it did others from that of their pleasure. The great Napoleon had landed at Cannes on his return from Elba, and, in company with the other English visitors to Paris, Dr. Jacob started for London, this time, however, not making his journey on foot; and upon his arrival in that city spent some months attending the clinics of Sir Astley Cooper, then in the zenith of his fame, of Sir Benjamin Brodie, and of Sir William Lawrence, with all of whom he became intimately acquainted, and whose friendship he maintained to the periods of their death.

Upon his return to Dublin, Dr. Jacob quickly attracted the attention of Macartney, then Professor of Ana-

tomy in the University of Dublin, a man remarkable for the soundness of his knowledge and for the advanced character of his physiological teaching. He appointed him one of his demonstrators of anatomy, and for several years was he associated with him in establishing the character for high scientific culture of the Medical School of that University. Earnest and enthusiastic as Jacob had hitherto proved himself to be, during these years he excelled himself. With his own hands he contributed largely to the formation of that museum (especially to that portion of it illustrative of the absorbent system) which Macartney subsequently disposed of to the University of Cambridge, where it at present lies; whilst at the same time he made a series of exquisite anatomical preparations of the eye, both human and comparative, which, at a later period, he presented to the Royal College of Surgeons, of the Museum of which body it still constitutes a principal ornament. During the prosecution of these anatomical investigations he made that remarkable discovery which has rendered his name immortal, but which, with the true modesty of genius, he simply announced in a paper in the "Philosophical Transactions" for the year 1819 under the title of an "Account of a Membrane in the Eye recently discovered," which membrane, however, with the unanimous consent of all subsequent writers, has been called, after him, the "Membrana Jacobi."

Some few years after this, circumstances induced him to sever his connection with the University of Dublin, and he then, in conjunction with Graves, Marsh, Cusack, and Hart, founded the old Park Street School of Medicine and Surgery, for a long time one of the most successful private schools in Dublin, from which, in the year 1826, he was translated to the Professorship of Anatomy and Physiology in the School of the Royal College of Surgeons in Ireland, of which body he had been elected a member so early as 1816. Thenceforward his every thought was devoted to the College, and no amount of labour, no amount of self-sacrifice was deemed by him sufficient to ensure its advancement. At that time hospitals were fewer in number in Dublin, and more exclusive than they are at present; many of the Professors in the College School were unprovided with such appointments. To meet this condition of affairs, the bold idea crossed his mind of starting an hospital which should be officered by Professors in the College of Surgeons' School. Acting upon this idea, he associated with himself in the enterprise Professors Benson, Harrison, Apjohn, Beatty, and Houston; and in the year 1832 the City of Dublin Hospital came into existence, since which period it has grown into the position of one of the leading charities of the city. For several years he had been now taking an active and influential part in the medical politics of the country, and his spirit had been frequently chafed at what he, perhaps justly, conceived to be unfair comments in the English journals, and at the want of *esprit de corps*, and ignorance of current medical politics on the part of Irish medical men. To remedy these evils, he determined upon starting an organ for the expression of Irish medical opinion, and, in conjunction with Dr. Maunsell, in the year 1838, he brought out the first number of the DUBLIN MEDICAL PRESS. Of this paper for many years he was the sole proprietor and editor, and in its pages appeared many of his most important contributions to the literature of his profession. For years it was impossible for man to toil more laboriously or more conscientiously than did Dr. Jacob, nor have many men left richer fruits after them as the result of their labour than he did. His time, apparently, was fully occupied with the duties of his Professorship, in the discharge of which he was pre-eminently punctual and energetic, attracting large classes of students, whose boast in subsequent years it was that they had been his pupils. In editing his journal, in which, week after week, would appear leading articles from his pen—easily recognisable by the vigour and terseness of their style—in the large calls made upon his time by his extensive private practice, and in the discharge of his hospital duties, with which he would allow nothing to interfere, it could scarcely have been expected

of him to make many important contributions to the literature of his profession; and yet, in the midst of all his multifarious avocations, many such flowed from his pen, prominent amongst which, as being standard, may be mentioned his essay on the Cetacea, published in the *Dublin Philosophical Journal*; his papers on the Eye, in the *Cyclopædia of Anatomy*, on Ophthalmia and Amaurosis, in the *Cyclopædia of Practical Medicine*; on Diseases of the Eye, in the *Dublin Hospital Reports*, and in the pages of this journal; on the Anatomy of the Eye, in the *Medico-Chirurgical Transactions*; his essays on Anatomy, Zoology, and Miscellaneous Subjects, on Inflammations of the Eye-ball, on Cataract, together with many other papers, too numerous here to enumerate. His fame as an original thinker and investigator, which mainly rested upon his discovery of the "Membrana Jacobi," was sustained by his original description of the disease which long bore the name of Jacob's Ulcer, and is now more commonly known as the rodent ulcer, and by his restoration to surgery of the operation for the solution of cataract through the cornea by the curved needle, now known as Jacob's Needle. His work on "The Inflammation of the Eyeball," though presented to the public in a most unpretentious and uninviting form, has always been recognised by contemporary writers on ophthalmic surgery as one of the most sterling works on the subject in the English language. His distinction as a surgeon, anatomist, and writer was not, however, attained without the exercise of continued and persevering labour and self-sacrifice. For many years of his life it was his unvarying habit, after the completion of a laborious day's work, and having dined, to retire to bed for a couple of hours' rest, when he slept profoundly; he then got up, had tea, and devoted the greater part of the night to reading, writing, and preparing notes for his anatomical lectures. His retiring disposition and little regard for convivialities enabled him to devote almost all his midnight leisure to such labours, which were to him labours of love, and his perseverance in such a system bore good fruit in the many articles which flowed from his fertile and versatile pen.

To those who had but a superficial knowledge of Dr. Jacob, his manner may have appeared brusque, but to those who were intimately acquainted with him, the generous, disinterested, honest, and thoroughly independent nature of his character was well-known. Never could he be persuaded to do an act which savoured even in the remotest manner of selfishness, or of self-advancement. Thoroughly honest and disinterested, he never would accept of any testimonial from his professional brethren in recognition of the many sacrifices which he had made in their behalf. A remarkable illustration of this statement occurs to the writer's mind. About the year 1860 a number of his admirers determined, despite his well-known feelings on the subject, to present him with a mark of their appreciation of his services, and a committee was organised for the purpose of receiving subscriptions, which flowed in rapidly, and the time came round when it was necessary to ascertain the form which it would be most agreeable to his feelings that the testimonial should assume. Sternly and resolutely he declined to receive anything, and, in consequence, the committee were at their wits' end to know what to do with the subscribers' money, when a happy thought occurred to them that it should be spent in striking a medal in his honour, and they confidently calculated he would not refuse to receive one of these. The medal was struck, and a beautiful specimen of die-sinking it is, its execution having been confided to an eminent Irish artist, Mr. Woodhouse, that intended for Dr. Jacob being struck off in gold, whilst those for the subscribers were struck off in bronze. The committee waited on Dr. Jacob to request of his acceptance of the medal intended for him, when he replied: "I cannot accept of this or any other testimonial, but if at my death you still think that I deserve it, you may nail it on my coffin!" As stated, this medal is a beautiful example of the die-sinker's art. The obverse bears a life-like head and bust of Dr. Jacob, and on the reverse are found these

words: "Arthur Jacob, M.D., F.R.C.S.I., Prof. of Anat. and Phys. Roy. Coll. of Surgeons in Ireland. In commemoration of eminent services rendered to science and the medical profession in Ireland. 1860."

Full of honours, full of years, he at last, in the unimpaired vigour of his intellect, resolved on retiring from the services of that College which he had loved so well, and over which he had for so many years with unceasing devotion presided. Thrice nominally its President, for many years past had he been practically recognised as its chiefest counsellor—its brightest ornament, and in adopting this step, and in voluntarily separating himself from an institution in which he took so deep an interest, and from colleagues, most, if not all of whom, had been his own pupils, his heart must have felt a pang which nothing could assuage save the conviction that in thus retiring he was but acting in accordance with that spirit of loyalty to its interests which had actuated him throughout life. Doubtless he felt that the work which in former days had been but a labour of love was getting past his powers, and he desired to make room for younger, but certainly not for abler, men. Be this as it may, the love he bore the College, the interest he took in its welfare, abated not on his retirement, for one of the most recent acts of his life was to present to it his library and valuable collection of drawings. The College on their part have done him all the honour in their power. Thrice they elected him their President; a life-like portrait of him has been put up in their board-room; a special room has been allotted for the reception of his library, in which is placed his bust. But on honour in their power to bestow could be considered at all as equivalent to the lustre shed on their body by having had such a man as their Professor.

The career of Arthur Jacob, which we have thus briefly sketched, will have manifested to our readers the peculiar characteristics of the man. They were his unflagging energy, his unchangeable honesty of motive, and his almost faulty sense of personal modesty. His activity and perseverance—a well-marked inheritance from his father and grandfather—carried him over all obstacles, and brooked no opposition, and thus enabled him to overcome difficulties from the encounter of which a less energetic man would have shrunk. He devoted heart and soul to his public duties, he put behind him throughout his professional life all thought of self-interest, and, in flying from the suspicion of self-aggrandisement, he sacrificed many of those reasonable expectations of public and pecuniary advancement to which his labours and his talents justly entitled him. With him self-negation was an eccentricity, and though he at all times experienced just pride in the respect and affection so freely shown him by his professional brethren, and lived for little else than the enjoyment of their esteem, yet did he persistently discourage any recognition of his service which might obscure the disinterestedness of his motives. Such faults as he had may be truly said to have been the offspring of his constancy to his well-loved College and of his intolerance of disingenuousness, or what he considered professional trickery in others. The warmth of his views on these subjects cost him much personal profit, but gained for him, even amongst those who did not sympathise with such feelings, a thorough respect for his disinterestedness, and a deep admiration for his talents and perseverance. There have been few men in our profession respecting whose policy and acts there have been so many opinions. There has been none respecting the greatness of whose characteristics and the honesty of whose objects so perfect and honourable a unanimity of feeling now exists.

The plot of ground facing the new Thames Embankment, given to King's College through the First Commissioner of Works, is already covered with a handsome structure, which will be utilised for the physiological and microscopical departments of the College. The work is nearing completion, and is expected to be ready for the reception of students in a very short time.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 30, 1874.

### NÉLATON'S METHOD IN CHLOROFORM NARCOSIS.

THIS was the subject of two communications in the Surgical Section at the Norwich meeting. The method simply consists in inverting the body, and the results are described as most satisfactory. Nélaton believed that death resulted from anæmia of the brain, caused by the direct action of the chloroform. He sought to avert the catastrophe by the simple plan of inverting the patient.

Dr. Marion Sims related a case in which Nélaton was present, when, in the midst of Dr. Sims' operation, the chloroformist, Dr. Campbell, said, "Stop! stop! No pulse, no breathing!" and, looking to M. Nélaton, he said, "Tête en bas, n'est-ce pas?" Nélaton replied, "Certainly; there is nothing else to do." Immediately the body was inverted, the head hanging down, while the heels were raised high in the air by Dr. Johnston, the legs resting, one on each of his shoulders. Dr. Campbell supported the thorax. Mr. Herbert was sent to an adjoining room for a spoon, with the handle of which the jaws were held open, and I handed M. Nélaton a tenaculum, which he hooked into the tongue, and gave in charge to Mr. Herbert; while to Dr. Beylard was assigned the duty of making efforts at artificial respiration, by pressure alternately on the thorax and abdomen. M. Nélaton ordered and overlooked every movement, while I stood aloof and watched the proceedings with, of course, the most intense anxiety. They held the patient in this inverted position for a long time before there was any manifestation of returning life. Dr. Campbell, in his report, says it was fifteen minutes, and that it seemed an age. My notes of the case, written a few hours afterwards, make it twenty minutes. Be this as it may, the time was so long that I thought it useless to make any further efforts, and I said, "Gentlemen, she is certainly dead,

and you might as well let her alone." But the great and good Nélaton never lost hope, and by his quiet, cool, brave manner he seemed to infuse his spirit into his aids. At last there was a feeble inspiration, and after a long time another, and by-and-by another; and then the breathing became pretty regular, and Dr. Campbell said, "The pulse returns, thank God; she will soon be all right again." Dr. Beylard, who always sees the cheerful side of everything in life, was disposed to laugh at the fear I manifested for the safety of our patient. I must confess that never before or since have I felt such a grave responsibility. Again and again the same scene was enacted, and was graphically related by Dr. Sims, who related a second equally successful case.

Sir John Rose Cormack related, at the same meeting, a case in which the method had proved successful, although the patient remained for a much longer time in a precarious condition. In fact, his case was one in which the poisonous effects of the chloroform continued for a long time, as in those described by Casper and others.

Dr. Richardson, in consequence of Sir John Cormack's case, has lately performed an experiment, which he thus relates in a letter to Sir John:—

"A large strong rabbit was put to sleep with chloroform, and the administration was continued until the animal had ceased to breathe. Tracheotomy was immediately performed: a tube connected with the double acting bellows was inserted into the trachea, and artificial respiration was set up. At the same time, the animal was suspended by its hind legs, with the head downwards. The artificial respiration was steadily carried out, in the most systematic manner, for fifteen minutes, but there was no sign of restoration of the circulation. The animal being still suspended, I next laid open the thorax, and exposed the lungs and heart. The lungs were discovered to be responding perfectly to the action of the double bellows; but all parts of the heart were at rest, except the left auricle: this, charged with red arterial blood, was contracting; the other parts were so dead that they failed to respond to the intermittent galvanic current, although to the same current all the voluntary muscles responded vigorously, and continued to do so for an hour. I observed that the right cavities of the heart, the auricle, and ventricle, were tense with blood. I therefore let the animal down to the horizontal position; and when by this means the pressure of the blood was relieved, the auricle, and afterwards the ventricle, made a few feeble contractions under stimulation. No sufficient force was, however, exerted by the heart to make the blood traverse the pulmonic circuit; and, I may say, there was not at any time an indication of recovery.

"How far the effect of inverting the body was useful in the two cases you have named, it is difficult to say, because in both artificial respiration was employed, and this in itself is so remarkable a means of restoration, that the effects of it have to be seen to be realised. By artificial respiration, I have resuscitated an animal *seven minutes* after its respiration

had been stopped by the inhalation of chloroform; and there are cases in the human subject in which, after complete failure of the respiratory power from chloroform, artificial respiration has restored life, the body being retained in the horizontal position. It would be good practice, nevertheless, after the experience of the cases you have related, to add inversion or partial inversion of the body to the process of artificial respiration. The inversion should not be long sustained; if it be, the heart might be paralysed on its right side from the pressure of the blood, but it should be alternated by return to the horizontal line, the artificial breathing being zealously sustained during the whole time.

"In certain cases, where the right heart is demanding the stimulus of blood to enable it to contract with effect, the required supply of blood may thus be obtained from the veins below the heart, and the pulmonic circulation may be restored—a result, if it be instantly resorted to, that will almost of a certainty render artificial respiration successful in restoring life."

#### THE OPENING SESSION.

To-morrow is October the 1st, the opening day at the English Medical Schools, and no doubt many of our readers are anticipating the pleasure of hearing one of the introductory lectures, and of meeting there old friends. Such associations carry us back to student days, when life was fresh, and the claims and dignity of the medical life were expounded by the orators of those days as they will be to-morrow by their successors.

We shall not attempt to anticipate the advice that will be offered to students by those who have been selected to perform the great ceremony of the year, the more especially as we shall next week have to report the proceedings, or publish such portions of the addresses as may seem of special interest to our readers.

We have for several years past published *in extenso* the lecture at the London Hospital, and shall follow up our custom by printing that of Dr. Fenwick, to be delivered to-morrow at that hospital. This we shall, as usual, supplement by abstracts of or extracts from the other orations, and thus, as far as space will permit, enable readers at a distance to realise the event of the day.

In spite of some attempts to depreciate introductory lectures, and of the fact that at one large hospital they have now for several years been omitted, the custom still holds its ground, both in London and the provinces, as well as, though a little later in date, in Ireland and Scotland.

We are the more desirous that it should be continued, since of late years an interest in these productions has been evinced by the public, as seen in the fact that the daily papers now give some reports of the proceedings. This is well, inasmuch as questions relating to medical education and practice, as well as many points of professional importance, are so mixed up with social matters that it is more desirable for the public to be interested in them. Had our professional interests been understood, our social value fully appreciated, it is probable we should long since have been able to obtain legislation on numerous points that have hitherto been shelved. Let us, then, not

shrink from the publicity that has been directed to our profession in reference to education. Rather let us avail ourselves of it, and make our appeal for the reforms so much needed.

Not that we advocate that the day should no longer be regarded as one of supreme interest to the fresh men. They are entitled to, and will no doubt receive their full share of consideration. We need only hope that the good advice they will receive may be faithfully followed. Then the session of 1874-75 will indeed be one from which many a good and true follower of the Great Healer will date the commencement of a noble life-work.

There are, too, others who will perhaps take fresh courage. Older students will renew their vows as they come back to their work. Practitioners—and what are they, or should they be, but older students?—who come back for the 1st October to their *alma mater* will be welcomed, and most of them will meet their fellows. To some, indeed, this is the only day on which they have the chance of recalling old times and faces, and so correcting the memory as they learn anew what ravages time is making, for while many a face looks older, and many a form bears other marks of the years that have past, not a few will realise afresh the blanks that death has caused in the list that is always growing less.

These blanks form the saddest feature in the medical red-letter day, the only consolation being that which happily we constantly hear in our profession, that those called away have in their day fought a good fight.

In this may we follow them, as at the opening of a new session we once more take our places among the audience and listen to the exhortations appropriate to the occasion.

## Notes on Current Topics.

### Hospital Sunday in Dublin.

It will be recollected that the possibility and expediency of instituting an Hospital Sunday in Dublin has been under discussion for two or three years, the proposal having been originally started by the late Dr. Eames. Last year the movement took a practical shape, and meetings were held at which most of the hospitals were represented. The movement then received a severe blow from the refusal of the Roman Catholic hospitals to co-operate, yet it did not yield to that discouragement, but was still intended to be carried into effect at an early date. We regret to observe that some of the hospitals—notably the Meath—who had, in the first instance, joined the movement, have now fallen away from their adhesion to it, and their representatives have issued a manifesto against the proposition. Although we regret this action on their part, we cannot deny them the justice of making public the essential parts of this document.

"The advocates of the Hospital Sunday movement calculate the probability of success from experience gained in England, where the Hospital Sunday has been instituted with a certain amount of advantage that cannot be reasonably expected in Ireland, the condition of the two countries being so totally different. In England the entire population, without distinction of sect or creed, are united to

carry out the object; the people are generally wealthy, and the large Protestant majority especially so. In Ireland every condition is reversed. The large majority of the inhabitants of Dublin, 205,800, are Roman Catholics, of whom very few will contribute anything. And the immense majority of patients are also Roman Catholics. Numerous annual donations and subscriptions will be commuted for an annual contribution on Hospital Sunday; and that being distributed on some basis not yet fully defined, will leave those institutions that have hitherto been benefited by charity sermons and their own special collections, due to their own special exertions, comparatively destitute. But financially what is likely to be the result? London, the most wealthy and charitable city in the world, with nearly four million inhabitants, where Jew and Gentile, and all without exception, contribute to the Hospital Sunday Fund, only yields about 1½d. per head per annum, and this year's collection shows a diminution compared with the previous year. The 52,690 Protestants of Dublin would in the same ratio only afford £373; and even assuming that the Hospital Sunday collection should quadruple the ratio of London, it is evident that the ordinary subscription list being prejudicially affected, the gain must be nominal. The mode of distribution of funds thus collected, as proposed, is open to objection. The system is intended to be based on the amount of subscriptions received by each 'hospital,' and the 'work done' during the previous year. An average of years, both for subscriptions and work done, might be less objectionable. But here an important question arises—What is an hospital? And what is to be included in the terms 'work done?' In the Convalescent Home patients are interned for a fixed period of three weeks; in the Stewart Institute, for five years; and in the Hospital for Incurables, for life. Are these 'medical charities' within the scope of the Hospital Sunday movement, and how is the 'work done' 'relatively' to be measured? Is an hospital with large dispensaries—aural, dental, and ophthalmic—or simple dispensaries unconnected with hospitals, to rank with hospitals proper? How are they to be dealt with; and if dealt with, how is the work done to be ascertained? The matter of distribution is to be left to the discretion of 'persons disconnected with any hospital'; and it is therefore certain that charitable persons most acquainted with the working and needs of such institutions, and most likely to form a correct judgment, are precisely those whom it is proposed to exclude. If the whole community were to throw itself earnestly into the movement there would be a reasonable possibility of success, and the experience of other places would strengthen the hope of it; but with the charitable feelings and means of a Protestant minority, strained to maintain institutions which, besides scarcely providing for the poor of their own creed, afford relief to the numerous Roman Catholic poor, the movement will, in all probability, only disturb the present direction of charitable distribution, without adding materially to its volume."

### Dublin Sewage.

THE three engineers who were appointed by the Corporation, under pressure from the Government and the citizens, to frame a scheme for dealing with the Dublin sewage have reported. They had before them no less than fifty-seven different schemes, none of which were feasible. They have submitted a plan of their own, at a cost of about £160,000, and of £30,000 for a catchment reservoir, on Bateman's plan, at Ballysmutten, near Blessington, for flushing purposes. What they propose to do is to bring the sewage through intercepting sewers to two reservoirs on each side of the river far down, the sewage to be thence carried out to deep sea by the tide, which they say will effectually accomplish the intention. The cost of these works, though

not more than a fourth of that of the original scheme, will still be sufficient to raise a serious economic outcry, and really the citizens may be excused for an indisposition to incur great expense when it is remembered that the house taxes in Dublin amount to 9s. 2d. in the pound on the house valuation, or nearly one-half the rent.

We, of course, anticipate a violent opposition from the inhabitants of Clontarf and Ringsend, where the sewage reservoirs are to be situated, and probably a *veto* on the part of the Port and Docks Board, who will not allow their river-bed to be interfered with. Antagonism of this sort is, however, inevitable, and if the scheme be a good one we hope that such obstruction will not avail.

### Adipocere.

DURING the last few days the profession in London has had ample illustration of the process of conversion of muscle into that spermaceti-like substance known as adipocere, in the body of a woman which had been dredged from the Thames. After being embedded in the mud for probably two or three years, upon rapping the body it was hard, and perfectly resonant, and the whole of the internal organs were converted into a solid mass, which, like the rest of the body, when cut into, had the consistence and appearance of hard discoloured wax. One leg was absent, which Dr. Worboys was of opinion still remained embedded, the weight of mud having separated the parts when pulled up by the dredger. The head was resting upon the left hand, and the hypothesis is that the woman had laid down on the shore of the river at low water to sleep, or in a drunken state, and become suffocated.

### Scarlatina in Dublin.

FROM the Registrar-General's weekly return, which we publish elsewhere, it appears that the number of deaths registered in the Dublin Registration District for the week ending the 19th inst. amounted to 180, equal to a mortality of 30 per 1,000 of the population. Of these 62, or 34.4 per cent. were caused by zymotic diseases. Scarlatina proved very fatal during the week, the number of deaths from it amounting to 34, "exactly double the number registered during the previous week, and the greatest mortality from this disease in any week since the Registration Act came into operation in the year 1864." The total number of deaths from this disease registered during the current year amounts to 531, as against 233 registered during the entire of last year.

### The London Hospital Saturday Fund.

THE Secretary of this Fund writes to us as follows:—"As Hospital Saturday is now so close, I feel assured you will kindly accord to it the support of your invaluable journal, and with this view I respectfully ask that you will permit me to inform your readers that the Directors of the Crystal Palace, with the generosity and public spirit which characterise all their proceedings, have arranged a fête for the benefit of Hospital Saturday on the 5th of October next. The arrangements for this fête are of a magnificent nature. It will be only fair, therefore, to the Directors, that the public should evince their interest by being present in large numbers."

### The late Dr. Anstie.

A LARGE and influential meeting of the professional and private friends of the late Dr. Anstie was held last week in London, for the purpose of taking steps to raise a fund to be applied in perpetuation of Dr. Anstie's memory, and in recognition of his public and professional services. Dr. George Johnson presided, and among those present were Drs. Andrew Clark, Sibson, Murchison, Burdon Sanderson, W. Playfair, Liveing, Duffin, Douglas Powell, Wharton Hood, Sturges, and Glover, Messrs. Macmillan, J. S. Storr, T. H. Hills, John Wood, Henry Smith, Christopher Heath, Henry Power, Bond, Netten Radcliffe, Brudenell Carter, and many others. Dr. Burdon Sanderson proposed the following resolution, which was seconded by Dr. Glover—"That, considering the labours of the late Dr. Anstie for the promotion of science, and the circumstances of his untimely death, it is desirable that some permanent memorial of his career should be established." By subsequent resolution a large committee was appointed to carry out the objects of the meeting, and Mr. J. S. Storr was appointed treasurer, and Dr. Wharton Hood and Mr. Brudenell Carter joint secretaries. An executive committee was also nominated, and an opinion was expressed that the circumstances of Dr. Anstie's death in the discharge of his duty, as well as much of the work which he had done during life to ameliorate the condition of the poor, were sufficient to justify an appeal to the general public as well as to his own profession.

A meeting of the Council of the Westminster Hospital Medical School was also held, when the following sub-committee was appointed to collect subscriptions from the hospital and school in connection with the above fund:—Dr. Fincham, Dr. Gibb, Dr. Allchin, Mr. Cowell, Mr. Bond (honorary secretary), Dr. Dupré, with power to add to their number.

### The Latest about Cremation.

THE manner in which Sir Henry Thompson's famous proposal has been taken up in all civilised countries leaves little room to doubt, says the *American Clinic*, that cremation, as a means of disposing of the dead, will soon supersede inhumation. The German Cremation Society, in New York, numbering about 450 members, have decided on erecting a suitable hall, with walls of iron, 50 ft. by 44 ft., containing a rotunda supported by eight pillars. In the centre there will be erected an altar for religious ceremony, and upon a large stand in front of this will be placed the coffin. The ceremonies ended, the coffin would be gradually lowered by means of screws into a furnace, where it would be submitted to a hot-air blast of 1000 degrees Fahrenheit. It is calculated that complete cremation would take place in an hour and a half, after which the coffin would be again returned to the altar. The ashes would then be gathered and placed in urns provided by the relatives of the deceased. Connected with the furnace there will be an apparatus for condensing the gases and smoke.

By the will of the late Mr. Bryce Allan, of Liverpool, merchant, the Liverpool Northern Hospital receives £500, the Southern Hospital and the Liverpool Medical Museum £300 each, and the Liverpool Royal Infirmary £200.

### Elimination of Alcohol.

THE lamented death of Dr. Anstie gives additional interest to the result of his researches on this subject, published in the *Practitioner*.

Experiments were made by Dr. Anstie and Dr. Dupré, with the view of ascertaining as nearly as practicable whether alcohol to any appreciable extent escapes unchanged from the body of an animal which has ingested it. The animals chosen for experiment were dogs, which approach most nearly to man in their capacity for resisting the effects of alcohol. The experiments were performed by the aid of a Pettenkofer's chamber, in which the animal was confined, while a current of air passing through the box was condensed in water. By this means all its excretions could be obtained and analysed.

The result of a series of these most carefully conducted experiments, including one where the entire animal was subjected to a sort of "destructive distillation," proves conclusively that within certain limits alcohol ingested by an animal becomes totally metamorphosed within the system, the percentage eliminated as such being almost inappreciable. Dr. Anstie concludes that quite 600 grains of absolute alcohol can be disposed of daily within the organism of an adult male without any perceptible injurious effect upon the bodily functions.

If alcohol be a force-producing food, it is probably of great value in that capacity, on account of the rapidity with which its transformations take place.

It is certain, however, that beyond a certain dosage, varying for the individual, it becomes a violent narcotic poison, the more dangerous that it cannot be eliminated to any considerable extent.

If alcohol does not disappear by oxidation, it must undergo some as yet quite unknown transformation, after which it must escape unrecognised in the excretions.

If alcohol, however, be indeed oxidised, and yet does not beget force which can be used in the system, this would be the strangest possible discovery. Considering the very high theoretical force-value of the 600 to 800 grains of absolute alcohol which millions of sober persons are taking every day, we may well be hopeless of any reasonable answer to the question—Why does not this large development of wholly useless force within the body produce some violent symptoms of disturbance?

### Unpleasantly Suggestive.

FROM an address by the President of the Massachusetts Society for the Prevention of Cruelty to Animals we quote the following:—

"It is estimated that about six per cent. of cattle, and about nine per cent. of sheep and swine, nearly 600,000 in all, annually die on the passage to market from the west, and a large portion of these are sold in our markets, either as meat, or rendered into cooking lard; while the cattle that get through alive, for the want of food and water, and by reason of the cruelty inflicted upon them, after losing on the average, in transportation, nearly a hundred pounds each in weight, from the most juicy and nutritious parts of the meat, come out of the cars full of fever, and with many bruises, sores, and ulcers; and these, together with smaller animals, to which the loss and suffering is, in proportion, equally great, are all sold in our markets for food."

### Treatment of Zona by Collodion and Morphia.

DR. BOURDON (*Canada Lancet*), Hôpital la Charité, after having tried a great many local means for treating the above disease, and checking the intense pain, has definitively adopted the following plan:—Without opening the vesicles, he paints all the diseased surface with a combination of collodion and morphia—collodion one ounce, morphia eight grains. The mixture must be put on pretty thickly. The pain ceases from the second day, and at the end of seven or eight days, when the layer of collodion is removed, all the vesicles have disappeared and there remains only a slight local redness.

The *Practitioner* will, we understand, in future be edited by Dr. Brunton.

It is proposed to nominate Mr. Darwin for the Lord Rectorship of the University of St. Andrews.

THE Congress of German Naturalists was opened on the 18th inst. Professor Virchow was present.

SIGNOR PONTI, who bequeathed a portion of his property to the Academies of Science of London, Paris, and Vienna, died in a lunatic asylum, and his will will be disputed.

DR. BURGGRAEVE, Honorary Professor of the University of Ghent, has formed the idea of celebrating the centenary of the discovery of vaccination by publishing a folio volume, on vellum, illustrated with the portrait of Jenner.

DR. SAMUEL SOMERVILLE, Treasurer to the Royal College of Physicians of Edinburgh, has just died from aneurism. As a mark of respect for the memory of deceased, the President, Council, and Fellows of the College accompanied the corpse to its last resting place in official costume.

MR. W. BRANSBY FRANCIS, surgeon, of Norwich, has succumbed to the fearful injuries received in the Norwich railway accident. Deceased was forty-nine years of age, and his untimely death has caused a profound feeling of regret throughout the large circle of professional and lay friends by whom he was known.

THE guardians of the Preston Union have deemed it necessary to issue special instructions to their vaccination officer to inquire regarding the number of children born in the union who are unaccounted for in the vaccination returns. This number amounts to 226, out of a total of 1,980 births in the union during the latter half of 1873.

M. DECROIX, a chief veterinary surgeon of the French army, gives the equine population of Europe as follows: Russia, 1,800,000; Austria, 3,100,000; England, 2,666,000; Germany, 2,500,000; Turkey, 1,100,000; Spain, 650,000; Holland, 300,000; Belgium, 260,000; Switzerland, 110,000; and France, 3,633,600.

FROM the calendar of the Royal College of Surgeons of England for 1874, which has just appeared, during the year from Midsummer-day, 1873, to Midsummer-day, 1874, 365 candidates passed the preliminary examination in general knowledge for the fellowship and membership of the College; 683 were admitted to the primary examination in anatomy and physiology, of which number 441 passed. The M.R.C.S. was granted to 342, and that of F.R.C.S., to 11 candidates after undergoing the required examinations. The total income of the College from all sources in the year amounted to £13,093 ls. 3d. The disbursements over the same period were £12,672 14s. 5d.

It is contemplated to erect a memorial statue in honour of Ephraim McDowell, M.D., of Kentucky, who is considered in America to be the *founder of ovariectomy*. The appeal for aid to the project is first made to the women of the world who have been rescued by ovariectomy; next to the members of the medical profession, whose resources have been so greatly increased; lastly, to all who appreciate this advance in surgery, and its originator as worthy of the gratitude of the human race. All contributions to the memorial fund should be sent by money-order or registered letter, addressed to Dr. James M. Keller, No. 58 Green Street, Louisville, Ky., who has been appointed secretary and treasurer by the committee.

We referred last week to the attitude of the Dublin Corporation with reference to the new Public Health system, anticipating, not without good reason, an opposition to every part of the sanitary duties except that which had to do with a little personal patronage. We observe that the Corporation having applied to the Local Government Board to receive a deputation on the subject of the Public Health Bill, in which they desired to point out certain impracticable features, especially in regard to financial considerations which have not been provided for, the interview was not afforded, and yesterday it was determined, by a large majority, to request the Under-Secretary for Ireland, in the absence of the Lord Lieutenant and the Chief Secretary, to receive a deputation on the subject. On this subject *Saunders's News-letter* says that it will be interesting to witness the manoeuvres of the Corporation to obstruct the working of the Public Health Act. When the Bill was before Parliament we remember the fierce hostility expressed to it by certain members of the Town Council, because they were to have no voice in the appointment or removal of the sanitary officers. The whole thing apparently resolved itself, in their opinion, into a question of patronage—a point on which our municipal authorities have always shown themselves peculiarly sensitive. The Chief Secretary, however, judged with accuracy the position held by the Corporation in the public estimation, and their suggestions were firmly and decidedly rejected. Having failed to get any patronage under the Act, they now seem bent on showing that it is impracticable, in other words, obstructing the operation of the measure and rendering it a dead letter. This, we trust, they will not be permitted to do.

## INDIAN MEDICAL NOTES.—No. XXVI

(FROM OUR SPECIAL CORRESPONDENT.)

SIMLA, August, 1874.

## "THE BRIGHTON OF INDIA."

TOWERING above Simla is a mountain knot formed by four spurs, termed Jakho, 8,300 feet, well wooded, dotted with houses, the base constituting a favourite five-mile ride round, sometimes through dark shrubberies where the trees have their trunks covered with mosses and ferns, where endless flowers, the honeysuckle, pinks, cowslips, daisies, buttercups remind us of England; sometimes over yawning precipices overlooking crevices and crags, industriously cultivated by hard-working hill-men, who, for five months a year, are snowed up. On the summit of Jakho stood a blue house of slate, the residence of a Fakeer, the original settler in 1816. In 1819 was the first hut built, simply of thatch, spars, grass, and mud; and in 1822, Kennedy House and others sprang up.

Lords Anherst, Combermere, Bentinck, Auckland, Ellenborough, Hardinge, Dalhousie, Canning, Elgin, and Mayo lived here in their turn to escape the heat. Simla, 8,000 feet, has a range of temperature of 40° to 80°; Nyna Tal, 6,200 feet, 42° to 69°; Darjeeling, 7,000 feet, 40° to 64°; Ootacamund, 7,400 feet, from 51° to 60°.

The difficulty about the capital of India is to combine a central position accessible within reach of sea and rail, within ear of everything, plenty of space, and a cool healthy climate, the latter condition obtained at Simla. On the northern side, the snow accumulated in the winter protects vegetation, which, encouraged also by melted moisture, flourishes in the summer, and the trees grow hardy and luxuriant. On the southern side the rain torrents wash away the soil, leaving the surface barren and bare.

The municipality funds, about £1,000, obtained from ground-rents, are spent on roads, drains, forests, markets, bridges, &c. Sanitation is paid for by a five per cent. assessment on house property, about £1,300, supplemented by £1,000 from Government, the bazaar improvements alone costing £6,000, about eight sanitary inspectors being employed. Besides two churches are Roman Catholic and Baptist chapels, Bishop Cotton's School, Punjab Girls' School, Christian Orphanage, convent and private schools. The club, with chambers attached, will suit whist-players and medical officers with fair pay who like their luxuries. As said before, Harding's Hotel is very good, excepting the bed-rooms, which are too small—Lowry's Hotel, two native hotels, accommodate bachelors; and for married people there are boarding-houses, fairly reasonable and comfortable, judging from rumour and personal knowledge. A furnished house involves endless outlay. I write all this down to inform medical officers, married and single, the latter only admitted at Harding's. Bring two servants, good clothes, and, as said before, plenty of money; bring uniform, for, at the risk of a reprimand, I appeared at Dr. Beatson's funeral and the Commander-in-Chief's levée in plain clothes, not at all according to Cocker. The library is capital.

There are three Government, besides private dispensaries, where lithotomy and other operations are occasionally performed. There are two civil surgeons in the Indian Service, appointed for two years, receiving their regimental pay, besides competing for practice amongst families of civilians, merchants, tradesmen, native shopkeepers, who may live up the sides of the mountain or down the deep ravines—often dangerous in the dark to man and beast, or during the drenching rains. The Viceroy and Commander-in-Chief, when up at Simla, have their own doctors, who may compete for the very limited practice. It even fell to my lot to attend, or be called in consultation, to a labour complicated with cardiac disease, provoked by rarefied air—to a case of blighted ovum, for a time considered placenta prævia; to officers with pneumonia or hepatitis, to ladies with diarrhoea,

to children suffering from thrush, diarrhoea, tabes mesenterica, worms, bronchitis complicated with meningitis, all interesting, some very anxious cases, which may eventually be detailed. How many of us would give years to recall the past of neglected opportunities in student days—the irrevocable past: the endless difficulties, the awful—frightful at times, crushing responsibilities of practice, the joys and sorrows influenced by our skill or stupidity should be impressed on the lad who inclines to idleness in the hospital or dissecting-room; no matter how naturally dense he may be, the industrious, plodding pupil must eventually succeed. He may never become rich; as the doctor's wife said in "Bleak House": "We are not rich in the bank, but we have always prospered, and we have quite enough; I never walk out with my husband but I hear the people bless him; I never go into a house of any degree but I hear his praises or see them in grateful eyes; I never lie down at night but I know that in the course of that day he has alleviated pain and soothed some fellow-creature in the time of need; I know that from the beds of those who were past recovery thanks have often gone up in the last hour for his patient ministrations. Is not this to be rich?"

In the army, having a fixed income, medicines, hospitals, appliances, we have many advantages not enjoyed by the civilian, and our place in the profession should be high. There are other doctors at Simla, so-called paper men—for instance, Dr. Bryden's work is tremendous; his services must be invaluable in collecting, arranging, and putting into shape the medical statistics of the army in India. It gives one a headache to pore his Herculean labours; but the air of Simla and the lively roses about his hospitable house are probably conducive to health and longevity.

The chemists, two in number, charge exorbitantly for drugs, and have it all their own way as regards hours of closing.

The nurses are widows of soldiers, pensioners, or settlers—some very attentive in desperate sickness, with a certain Mother Gamp flavour about them all. In 1837, according to Miss Eden, sister of Lord Auckland, then Governor-General of India, when a lady eight months' pregnant died (undelivered) of cholera, the doctor had to put her into a coffin, an officer screw her down, and the boys of the band carry the body to the grave, in deference to caste. Bad milk started infantile thrush, rendered fatal by excess of calomel; ladies would faint at dinner-parties, be tormented by fleas, be chilled into bilious fevers going out card-playing at night, some sickened of solitary *ennui*, others provoked phthisis or pneumonia by excessive dancing.

The immediate delirium of fever was treated by leeches to the head and narcotine internally; but from a really severe jungle-fever, aggravated by bad water, no one recovered. During the heat at Simla people remained in-doors from seven in the morning to six in the evening; during the rains, houses, rocks, and roads were washed down; landslips occurred as they do to-day; also clothes, carpets, furniture, food, and drugs become damaged by the damp. An eccentric doctor, once sent for to a child in convulsions, refused to prescribe, pleading that the patient was possessed by the devil, then rambled into a lecture about magnetic stones, the North Pole, and Solomon's Temple. Miss Eden also tells us of a cataleptic native who insisted on being buried for two months, and then dug up again.

About 2,000 feet below the Mall is a level garden, called Annandale, celebrated for vegetables, flowers, fruits, and grand old cedars, the apple-trees this year satisfactorily productive—a tea-garden kind of place, adapted for races, cricket, pic-nics, flirtations where wavering bachelors come to the scratch and are referred to papa. "Show me your last pay certificate, young man," was the celebrated old Jock's reply on such occasions. Down in the valleys, winding through groves of firs, pines, and jungle, are the waterfalls, descending from a height of about 100, 80, and 40 feet respectively—just worth visiting,

but a hot, tedious pilgrimage, involving wet feet, and fever occasionally. Down in the valleys also are the three cemeteries, first opened in 1823, very English-looking, and fairly kept, the graves relieved by the birch and willow, the myrtle and the cypress, also the mournful yews, clover, the passion-flower, purple hollyhocks; also certain plants in pots were noticed this afternoon, for instance, hydrangeas, petunias, roses, and fuchsias, surrounding certain tombs. Several young married ladies rest here; but I could not find the celebrated memorial to so and so, third and beloved wife, &c. Some casualties were accidental—falls over the cliff, &c.; it is a great pity the cause of death is not invariably inscribed. Sir Robert Barker, Sir Alexander Laurence, Sir Henry Godwin, Dr. Tritton rest from their labours in the Simla cemetery—spoiled by Norwood, Kensal Green, and Highgate; somehow the place did not please as expected—an indefinable something wanting. The only epitaph worth transcribing was over an old general, and will apply to us all—"God be merciful to me, a sinner."

## Literature.

### THE PSYCHOLOGICAL AND MEDICO-LEGAL JOURNAL. (a)

THESE are the two first numbers of the new series of the *Transatlantic Psychological Journal*, which has changed its title to the *Psychological and Medico-Legal Journal*. It is very ably conducted, and will bear comparison with any European publication devoted to the same special class of topics with which we are acquainted. The first paper in the July number is by Dr. Hammond; its subject, "The Effects of Alcohol upon the Nervous System," is treated in a thoroughly philosophical manner, without the slightest evidence of any latent prejudice for or against the general use of alcohol. It is, in fact, a well-reasoned and dispassionate examination of a very important subject. The conclusions at which the author of the paper arrives are based upon three series of experimental observations under three different conditions, and they may be summarised thus:—

1st. *The influence of alcohol when the food consumed was just sufficient for the wants of the organism.*—During this series of experiments the food was of such a character and quantity as to maintain the weight of the body at its normal standard, and the author found that the use of half-an-ounce of alcohol at each meal had the effect of slightly increasing the weight of the body, and slightly diminishing the quantity of carbonic acid exhaled, as well as the quantity of the urine and its solid constituents. The general health, he found, was not so good as usual; there was headache, as well as indications of increased circulation, and sensations of undue heat and oppression. The inference he draws from this series of experiments is, that when the system is supplied with an abundance of food, and when there is no special circumstance existing to render the use of alcohol advisable, its employment as a beverage is not to be commended.

2nd Series. *The influence of alcohol when the food was not sufficient for the wants of the organism.*—The food taken in this series resulted in a loss of weight, amounting to about .28 of a pound daily. Under the use of alcohol (same quantity as before), not only was the loss overcome, but there was an average increase of .03 of a pound daily. The effects upon the excretions were similar to those in the first series, but the general health was good throughout, and mental and bodily vigour normal. The author therefore concludes that, when the quantity of food is not such as to admit of the due performance of such physical

(a) *The Psychological and Medico-Legal Journal*, July and August, 1874. Conducted by W. A. Hammond, M.D., and T. M. B. Cross, M.D. New York: Christern.

and mental labour as may be necessary, the use of alcohol is to be commended.

In the 3rd series of experiments, in which more food was taken than was necessary, the ill effects of alcohol were more marked than in the first. Headache was constantly present, the sleep disturbed, the pulse increased in frequency and force, and there was a general feeling of *malaise*. The body continued to increase in weight above the ratio which existed before the alcohol was taken, and the excretions were diminished in quantity. He comes to the general conclusion that alcohol must be regarded as an article of food, and that it retards the destructive metamorphosis of tissues.

He then proceeds to the consideration of alcohol in its poisonous effects upon animals and men, and concludes with a very able sketch of the nervous diseases produced by its abuse. The paper is a valuable contribution to the study of the physiological effects of alcohol.

In addition to this article the number contains a translation, by Dr. Lincoln, of Boston, of Professor Benedikt's paper on "The Laws of Topographical Diagnosis in Chronic Diseases of the Nervous System." The paper is a very able one, and presents an excellent synopsis of the laws of localisation of the symptoms and groups of symptoms in spinal and cerebral nervous affections.

The notices of contemporary literature are marked by extensive reading and considerable literary ability; in particular, the critical notice of Dr. Maudsley's recent volume upon "Responsibility in Mental Disease" is written with singular ability and good sense.

The number for August may be said to consist of two papers, the first from Dr. Hammond, upon "Morbid Impulse," the second from Dr. Cross, upon "The Treatment of Sciatica." Both are able contributions to the literature of the subjects with which they deal.

#### MATERIA MEDICA AND THERAPEUTICS. (a)

In the preface to the volume before us the author states that his work is a portion of a complete one on *Materia Medica* eventually to be published, and that the succeeding portion will contain the inorganic remedies, the alcohols, ethers, &c. If what we have received be a true index of that to follow—and of this we have no misgivings—a very effective work on *Materia Medica* will be the result, at once most useful to the student, to the practitioner, and not less to the truly scientific only.

We congratulate the author on the mode adopted by him in order to simplify the rather tangled skein on which he so industriously manipulated, removing what he considered to be superfluous threads, and finally placing before us the result of his labours, so far, in a neat volume, issued from the press in the publishers' usual style of effectiveness.

Under the natural orders Dr. Phillips describes all plants. In the first division of every article we have a botanical description of the plant, the second enumerates its active ingredients, the third the physiological effects of the drug, the fourth its therapeutic action, and the fifth and sixth its different preparations, doses, and adulterations. Such being the basis of the work, the author culls from the subject on which he treats all matter that appears to him superfluous or lacking practical use and application, and accomplishes his task in a very creditable manner, ending it by giving us a double index, on reference to which any subject or remedy dealt with may be at once turned to—saving both the time and trouble of the reader. We append a specimen of the mode which the author has adopted, selecting for obvious reasons one of the shortest descriptions in the volume:—

"RHAMNACEÆ—the Buckthorn Family.

"An order of about 250 exogenous trees and shrubs with simple undivided and usually alternate leaves, and

*Materia Medica and Therapeutics (Vegetable Kingdom).* By Chas. D. F. Phillips, M.D., F.R.C.S. London: J. and A. Churchill, 1874.

small and usually greenish flowers, the parts of which are in fours or fives. The perigynous stamens are opposite the petals, and the superior and two to four celled ovary is seated upon a fleshy disk. The fruit is either fleshy or dry. The order abounds with plants possessed of active properties, the most noted of them belonging to the typical genus *Rhamnus*."

"PURGING BUCKTHORN (*Rhamnus catharticus*).

"1. *Description*.—A spinous shrub, six to ten feet high, common in English hedges, with ovate, glabrous, and serrated leaves, and abundance of minute tetramerous flowers, followed by small globular black berries. The seeds, four in number, are smooth, elliptical, and plano-convex.

"2. *Active Ingredients*.—The purgative properties of buckthorn are probably due for the most part to an uncrystallizable bitter substance called *Rhamnocathartine*, the descriptions of which are somewhat vague. It has been questioned whether this principle may not be identical with *Rhamnine*, another ingredient of buckthorn berries, but the latter is almost, or quite tasteless, and can be shown by the microscope to present a regular crystalline structure. *Rhamnocathartine* must not be confounded with cathartic acid,  $C^{18}H^{19}N_2O^{12}$ , the active principle of senna, and found also in the bark of the *Rhamnus Frangula*. *Rhamnocathartine* seems to be a sure purgative in two or three grain doses for children, but is exceedingly disagreeable to take, and is slow in action.

"3. *Physiological Action*.—The juice of the berries causes great dryness of the mouth and throat, with intolerable thirst, nausea, in certain cases vomiting, griping pains that extend throughout the abdomen, and violent purging, the character of the evacuations being watery.

"4. *Therapeutic Action*.—The juice spoken of was at one time prescribed in dropsy, also in gout and rheumatism, but now is seldom employed, except in domestic practice, which regards it as a laxative, suitable especially to children in the form of syrup.

"5. *Preparations and Dose*.—Syrupus: Dose  $\frac{1}{2}$  to 1 oz.; for young children  $\frac{1}{2}$  drachm; to 2 drachms.

"6. *Adulterations*.—The berries of the *Rhamnus Frangula*, which contain only two seeds instead of four."

#### DEATH OF DR. ROE, L.R.C.S.I., &c., OF BRIDGENORTH.

WE regret to have to announce the melancholy news of the death of Dr. Roe, which occurred on the 17th September at his residence, Bridgenorth, Salop. Dr. Roe was educated in Dublin, where he passed the Royal College of Surgeons in 1863; deceased settled in Bridgenorth, Salop, where he gained in a short time the respect and esteem of all who knew him, and where he acquired a very extensive and lucrative practice; he was one of the consulting surgeons to the Bridgenorth Infirmary, which institution has by his death sustained a heavy loss. He contracted in the course of his professional duties scarlatina, which was rapidly followed by renal and cardiac complications, together with inflammation of the lungs, and he died in his arm chair leaving a sorrowing widow and several orphans behind. We regret to learn that one of the children has died, and others are ill of scarlatina.

IN another column we have recorded the case of an American girl, who died recently from eating clay. We have now to add another victim to extraordinary taste in the person of a shoemaker, on whose body an inquest was held on Saturday, at Manchester. The post-mortem showed that the stomach contained one pound ten ounces of nails, several pieces of half-inch square iron, and an awl without a handle. The jury returned a verdict of death from peritonitis, in accordance with the medical evidence.

## Correspondence.

### DR. WEST AND THE BRITISH MEDICAL ASSOCIATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Illness and consequent absence from town have prevented my seeing in print till to-day the resolution of the Committee of Council of the British Medical Association, forwarded to you by the solicitor of that body for insertion in your journal of the 2nd inst.

It may have appeared to others, as it did to me, that the publication of my letter, on which that resolution was based (if its purport had been what the resolution assumed), would have been a more satisfactory answer to my charge than any threat of legal proceedings.

My letter was in the first instance stated to have been destroyed. When that statement was withdrawn I challenged its production.

No reference having been made to it in the letter which accompanied the resolution of the Committee forwarded to me, I supposed it could not have been laid before them. On receiving an assurance to the contrary, I addressed to the Secretary a letter, of which I herewith enclose a copy. To that I have received no reply, and can merely repeat my dissent from the decision of judges who withhold the evidence on which that decision professes to rest.

Your obedient servant,

CHARLES WEST.

61 Wimpole Street, London, W.,  
Sept. 22, 1874.

[COPY.]

August 30, 1874.

SIR,—I have received your letter (with delay, owing to my absence from home), stating that the letter which I mention as having been referred to by the Editor was placed before the Committee, and read at their meeting.

This letter was stated to me, by Dr. Sibson, on the authority of the Editor, to have been destroyed. I therefore concluded that it could not have been placed before the Committee. I also had torn up the letter in which the Editor applied for permission to print my oration, but sought for and joined the fragments, and sent them to Dr. Sibson.

A like courtesy ought to have been extended to me, so far as to send me a copy of my reply, in which, as I assert, I distinctly refused the permission, and repudiated having ever made any such engagement as the Editor most incorrectly alleged that I had entered into.

The question of right or wrong, good faith or its opposite, turns entirely on the question whether I did or did not give the authority pretended. I deny it, and there, as far as I am concerned, the matter rests, and my opinion continues unaltered.

I am, Sir, your obedient servant,

CHARLES WEST.

F. Fowke, Esq., Secretary,  
British Medical Association.

### THE RELATIONS OF THE PROFESSION TOWARDS HOMŒOPATHY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As you have had the courtesy to insert my letter with my proofs, I am content to let your readers judge between you and me whether I have been guilty of "gross misrepresentation" in saying that the majority of the profession treat us as dishonest and immoral because we prescribe medicines on the homœopathic principle, and whether you are justified in asserting that "the medical profession regards with the most perfect toleration the theory and practice of *similia similibus*."

But if you will kindly continue your courtesy—or perhaps I should say your toleration—I would like to make a few remarks on a passage in your comments in my letter. You say, "Homœopaths are not admitted to association with the profession, &c., because it is impossible for intelligent minds to place

any charitable construction on the practice of infinitesimalism, or, in fact, to believe that it is anything but a fraud. Homœopaths may, if they like, be visionaries; but they must establish their claim to be considered to act with honest intention before they can be met as fellows by scientific medical men."

I have no desire to dispute your claim to a monopoly by your side of "intelligent minds;" but I would submit that whether so-called infinitesimal doses of medicines act or do not act under certain circumstances is a matter to be determined by experiment, and not by "charitable construction." Scientific belief is conviction obtained by evidence, and a belief based on any other foundation may be held tenaciously enough, but has no claim to be considered scientific. So, if your side assert that they believe infinitesimalism to be a fraud, we ask, where is your evidence to constitute your belief scientific? What if it should turn out that you have no evidence one way or other in connection with infinitesimal doses of medicine? What, in that case, is the value of your belief? Belief without evidence is merely prejudice. Your side object, perhaps, that you have had immense experience of the action of medicines. Granted; but not with infinitesimal doses. Your 200 years' experience of the emetic effect of a scruple of ipecacuanha will not enable you to tell how an infinitesimal dose of that drug will act in a case of vomiting.

Again, why are we to "establish our claim to be considered to act with honest intention?" In other departments of science is it considered necessary that their cultivators should give proof of honest intention? And, if not, why in therapeutics? Can an alleged fact in therapeutics not be considered on its own merits without proof of honest intention on the part of its propounder? Some time ago you did me the honour to notice favourably a pamphlet I published on the "Mechanism of Visual Accommodation." You considered my statements and experiments on their merits, and did not ask me for proof of honest intention. Why, then, should I be asked for such proof in reference to the action of infinitesimals in disease? Do therapeutic facts belong to the domain of morals, that they cannot be accepted, or even inquired into, without an assurance of honest intention on the part of those who put them forward? And will a therapeutic fact be accepted as true if the honest intention of its propagator is proved? If so, by all means let us furnish proof of the honesty of our intentions. But how is that to be done? Must we get a certificate signed by the clergyman of our parish, or a magistrate of our borough, to the effect that we are honestly-intentioned people? or will a testimonial from two reputable householders do? And are "scientific medical men" to ask for certificates of honesty all round before they will enter into fellowship with one another? You know that to ask for proof of honest intentions in regard to other matters for scientific experiment would be looked upon as an intentional insult, and we cannot help feeling that your side intend it as an insult to us.

Do you suppose the public believe you when you denounce us as dishonest, fraudulent, and "unworthy to be regarded as members of an honourable profession?" Of course, you know well they do not; but there is little doubt that the loss of consideration of the medical profession generally in the eyes of the public is in a great measure caused by the habit your side has so long indulged in of denouncing as dishonest and disreputable some of your colleagues for no other obvious reason than that they differ from you on some points of therapeutic doctrine and practice. This habit of knowingly bearing false witness against your brethren (for you know it is false to assert that our average morality and honesty are inferior to your own) cannot be indulged in without lowering the moral tone of those who practise it, and the whole profession suffers from this plan of making a question of therapeutics one of ethics, and assuming that a given method of practice is fraudulent in place of experimentally testing its value.

Your obedient servant,

R. E. DUDGEON, M.D.

53 Montagu Square, 10th September, 1874.

[We regret that the defence of the profession against the charge of trades-unionism which we are obliged to make, and the phrases which we are obliged to use, should appear insulting to homœopaths. We have no desire unnecessarily to hurt their feelings, and if we could express the same sense in more pleasant terms we would gladly do so. Our correspondent

asks us, "If we believe infinitesimalism to be a fraud, where is our evidence to constitute our belief scientific?" and he states that "belief without evidence is mere prejudice."

We have to remind our correspondent that the credibility of any statement and the propriety of close scientific investigation into the truth of such statement are matters of degree. No one in these days would consider it necessary to undertake an investigation into the existence of the philosopher's stone, which was said to turn all base metals into gold, nor would anyone be justly charged with unreasoning prejudice because, without inquiry, he denounced such pretensions as false. On the contrary, the man would be considered either mad, or a knave, who expressed in such properties a belief based upon the fact that their falsity had not been inquired into and proved. Whatever our correspondent may think, we cannot place infinitesimalism in any other category than that of the philosopher's stone, and we feel ourselves unable either to credit its professors with intelligent belief in it or to consider a scientific investigation a necessary preliminary to our declaration that it is a fraud.

The fact is, that infinitesimalism has become too much for the homœopaths themselves, and each successive exponent of Hahnemann's theories, even Dr. Dudgeon himself, manifests that he is ashamed of that part of his rule of faith by alluring over the subject. It would be honest in them to say plainly that they still held only a mitigated belief in billionths. Aye! but what about the patients who would not receive the ministrations of homœopathy at all? but that they think they are being cured by semi-invisible agencies!—Ed. M. P. & C.]

#### BATHING QUARTERS ON THE STRAITS OF DOVER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—We are often consulted by patients as to the best sea-side residence during the summer months, and I confess to have sometimes hesitated in giving any oracular response to such queries.

This summer, however, I have, I think, almost made up my mind in pronouncing the little town where I am at present writing these few lines as the most healthful spot of easy access to our citizens of London. The opinion that Folkestone is the *ne plus ultra* of health and purity has grown on me for the last fifteen years or more, as I have during that time had yearly occasion to pass through the town on my way to Paris or other continental resorts, and resided in it on several occasions. I know that other places have far greater attractions for the citizens of London—thus, I have often taken the dictum of Mr. Erasmus Wilson as true, and said to patients, when complaining of languor, "Go to Margate." The air of Margate is, I acknowledge, very bracing, and the pier at present existing is a most desirable place for obtaining ozonised air.

Ramsgate, too, has numerous advantages as a bathing place, as the famous "Ramsgate Sands" of Frith have made known to the eyes as well as the ears of us all. Both of these localities, too, have some pastimes in the shape of concerts, assembly-rooms, and other pleasures so eagerly sought after by the young. Still, to the eye of the severe lover of health, there is too much of the town element in both of those very favourite resorts of our London population to make either Ramsgate or Margate quite without reproach.

On the other hand, this, the birthplace of the immortal Harvey, is quite unparalleled in the purity of its air, whilst it is free from the pernicious element of town life I have referred to. Folkestone, as will be seen by the registrar-general's reports, is quite on a par with the healthiest rural parishes in England in respect to its low death-rate (only 16 per 1,000); and a good observer can readily perceive to what this immunity from epidemics is due. In the first place, the little town is, with some slight exceptions, exquisitely clean, one of the cleanest towns in England, and that is great praise, for, after continental cities, it is quite a pleasure to return to this country for its cleanliness alone.

There seems also to be no great collection of a very poor dirty class as there is in Boulogne, or most other towns where fishermen and their families abound; the beach, too, is shingly, which makes the sea-water pure and clear, and this pure water washes out the harbour and takes away all those bad odours which make Boulogne-sur-Mer so unbearable to persons well organised in their nasal mucous membranes.

The authorities of Folkestone have of late years evidently been desirous of improving their little town, and I fancy I trace the effects of trips to Boulogne—which doubtless some of the members of the Town Council have often made—in the erection of a bathing establishment after the model of the splendid Etablissement des Bains, at Boulogne, as well as the furnishing of that agreeable accompaniment of the bath—a band, which plays for two hours in the morning and two in the evening, and thus keeps the visitors out of doors.

There are only two points in the hygiene of Folkestone which appear to me to require much alteration: the first is the water-supply. I am convinced that there must be some organic matter in the water supplied to the town, as it certainly is so unpleasant to the taste that I, although a votary of water as the best of all summer drinks, could not use it except in tea. The next point relates to the opening of a sewer into the town end of the harbour: this ought to be seen to at once, by conveying the said drain beneath the railway into the sea at low water.

By the way, a word about sea-bathing. Why is it that in England almost the only hours of the day chosen for bathing are between 10 a.m. and 1 p.m., whilst at Boulogne I find the bathing-machines in requisition from early morning until nightfall. I think there is an idea among most physicians here that bathing before breakfast is not healthful, and I confess to sharing this view in the case of very fragile patients, who, I think, ought not to enter the sea until they have repaired their expended nutrition by a good breakfast, and allowed an hour or two for digestion of the same; but in the case of robust men and women I see no harm, but rather good, in the sea-bath, taken with a short walk before and after it, previous to breakfast, and this is the custom I prefer in my own person. There is something, I think, very invigorating and poetical in rising at an early hour on a bright summer morning and spending half-an-hour amidst the sparkling waves. The morning meal is then better assimilated than it would be if the bather lay in bed until breakfast-time. This year my sea-baths have rid me speedily of an uncomfortable rheumatic pain in my left shoulder, which has resisted all mere pharmaceutical remedies whilst in London.

Folkestone, I hear, has only some 10,000 inhabitants, and the most recently built portion of the town, called the *Lees*, is well laid out, and admirably clean and bracing, being situated on the top of cliffs from which, on a very clear day, and with a good glass, I am informed that the column of Napoleon at Boulogne, thirty miles distant, is visible. I doubt it.

The bathing establishment affords to the subscriber an excellent swimming-bath, a ball-room, and reading-room, and the establishment owns some fifty bathing-machines, which descend the steep shingle-beach by gravitation alone, and are hauled up as the tide flows by a windlass; so steep is the incline sometimes that the bather is at once in deep water, which is a little hazardous occasionally when the sea is high.

Boulogne, which I passed through some days ago, and where I have often passed some time, is certainly a most attractive sea-side residence on a pleasant summer day. Few towns have such a combination of distractions for the visitor from Paris or London as Boulogne. *Imprimis*, the Etablissement des Bains is quite a palace, and has, every evening during its season, balls for the young people, and concerts for all, as well as excellent reading-rooms, swimming-baths, &c. There is also a wonderful little theatre in that city of 49,000 inhabitants, which creditably perform some of the grand operas, such as Robert, or William Tell, &c., a feat I should think quite unattainable in small towns in our rather unartistic islands.

Boulogne sands, with the 200 bathing-machines, or thereabouts, present quite a brilliant spectacle at the end of July or in August. It is, indeed, for this reason, I suppose, that so many of our countrymen and women so often forsake the charms of English sea-side resorts and crowd into Boulogne, which, as I am about to explain, has many serious drawbacks for the invalid.

The errors I allude to consist of—firstly, the way in which the bed of the river Liane lies uncovered by water for some

time, twice every twenty-four hours, at low tide, sending forth noxious exhalations, which must be smelt in every room in every hotel along the quays. The only way, I think, of getting rid of this great blot upon Boulogne as a health resort would be to have large sluice-gates as far down the river as on a level with the point where the Folkestone steamers lie, which should only be opened at that time of the tide which would suffice to keep the whole of that part of the river facing the quays constantly covered with several feet of water. Until this be accomplished I am sure that Boulogne-sur-Mer, with all its many advantages, natural and artistic, will continue to be sharply visited by epidemics of diarrhoea, low fever, and the like.

My respected former colleague of the Metropolitan Free Hospital, Dr. Chator, has settled as practising physician in Boulogne in the Rue de Vieillards, after having served his adopted country, France, in that detestable struggle, the Franco-Prussian war, by working in the ambulances with his devoted partner, a French lady. He has, on this account, been admitted to practise medicine in France with his English degrees.

Dr. Chator, should he see this letter, will perhaps inform me whether the inhabitants of the lower parts of Boulogne, near the river, do not suffer from diarrhoea and low dynamic diseases more than they ought to do; also, perhaps, he may tell us how it is that Boulogne is provided, or rather left unprovided, with sufficient drainage. The English quarter alone is, in my idea, decently drained, that is, the quarter lying to the west of the Haute Ville. The streets in that part are quite healthy, and persons residing there suffer from none of the evils I hint at, so that residents who secure houses in that part of the town are fortunate in living in such a pleasant town as Boulogne-sur-Mer.

One feature in Boulogne is peculiarly agreeable to the medical mind, i.e., the fact that a statue has been erected there to the immortal Edward Jenner. It was placed in the present situation on the quays whilst a certain M. Livois was Maire, who, I think, was a physician. Perhaps there may be a statue of Jenner in London, but I certainly do not remember to have seen it. Do you, Mr. Editor?

And, talking of memorials to the real benefactors of mankind—those who strive to ward off death and pain—I was, a Sunday or two back, in the parish church at Folkestone during service, attracted by the desire of seeing the memorial window lately erected to Harvey, which is, I admit, rather a compliment to science.

Yet the discourse I listened to from the speaker was such as to make me fear that the genius of many Harveys will be needed to awaken some men to a true reverence for Nature and truth. Imagine my amazement to hear that certain young persons, spoken of by the clergyman, had been suddenly restored to health whilst in some critical fever by holding a cross in their hands and being prayed for by a certain portion of that Folkestone congregation. "Shades of Harvey," I mentally exclaimed, "how long will such heterodox opinions reign over men? How long will 'peculiar people' in and out of our churches and cathedrals continue to exhibit the ignorance of the dark ages, and the superstition of the 15th century?"

What a strange contrast, by the way, there exists between the customs of the two towns I have just spoken of, separated by a narrow strip of sea of thirty miles long, with respect to the keeping of Sunday. In Folkestone, on Sunday, tranquillity reigns supreme; there no bathing-machine is allowed to descend into the sea; every shop is closed, and those persons who indulge in the superfluous practice of smoking, or partake of alcoholic beverages, must indeed feel in difficulties in procuring them on a Sunday. In Boulogne amusements of all kinds are at their acme on Sunday, and such notions as regulating the sale of stimulants on that day seem not as yet to have caused any of the numerous ministerial crises which abound in France. Both nations have, I am sure, much to learn from each other in this matter. Our Sundays are so severe that the working-classes are forced into drinking and sullenness from deprivation of a little innocent amusement on their only holiday; whilst, on the other hand, Sunday in France is no holiday at all to many classes, a far worse evil than ours.

Another feature of "La Belle France" strikes one even in Boulogne, and that is, the growing distaste among all the respectable classes in that country for large families. On one occasion I was in a *hôtel garni* in Boulogne, in company with two young married couples, both of whom had been, I found,

married for some five years. On inquiry, I discovered that both of these couples were postponing the date of their family until their salaries became higher—quite a French idea, I thought. This year I overheard a conversation between a child of five years of age, who complained that there was no baby in the house to play with, and his mamma, who told him that a baby was too expensive, and "eat too many cakes."

I presume it is on account of all this determination to live within their means that the French owe their comparative affluence; for I agree with Lord Derby in thinking that France is the wealthiest nation in Europe, if her income be divided by her population. Let others vaunt the enterprise of Germany and Holland, and the zeal of these and other nations in pushing out into foreign countries; I shall always think that France is the only country which yet has even begun to face the question of poverty with any hope of combating it effectively.

In Paris lectures are all over by this time. Dr. Alfred Fournier has been lecturing every Thursday at the Lourcine on tertiary syphilis; and I have had the pleasure of translating, as you know, some of these classical lectures. My friend Dr. Charles Mauriac has also had clinical lectures on Saturdays at the Hôpital du Midi.

There seem to have been quite a number of lady-students at the Ecole de Médecine and the various hospitals connected with it last winter. Among the lady-students enrolled at la Faculté are Miss Alice Vickery, a lady who passed with much distinction the examination for chemist and druggist at the Pharmaceutical Society of Great Britain, and Mrs. Kingsford, a distinguished literary lady who, some years ago, edited a paper devoted to the interests of women. It seems that these ladies were granted admission as *étudiantes* on presentation of the certificate in Arts of the Apothecaries' Hall of London, which was taken as equivalent in their case to the Baccalaureats-ès-lettres and ès Sciences. They had to pay the fees, however, for these Baccalaureats.

On the question of women-doctors, I agree with Voltaire when he says, "Women are capable of all that we do: the only difference between them and us is that they are more amiable." I think Voltaire in this was far nearer the truth than Sir W. Gull or Dr. Maudsley, and am glad to see the great French writer in agreement with Mill and the lights of this 19th century.

Many of the lady-students at the Faculté and at the hospitals are M.D.'s of some university in the United States, that *Paradise of women*, as some call it, where more than 500 women, I hear, are already licensed to treat their fellow subjects. One of these ladies, Dr. A. Fulton, informed me lately that she was admitted freely to all the operations in the various hospitals, and treated quite fraternally by the *Mlle* of the Ecole de Médecine. Now that Mr. George Critchett, Mr. Erichsen, Dr. Wilks, and other of the ablest men of London are taking the part of female medical education, I suppose that ere long many of our own women will be allowed to compete for an honourable livelihood in England with ladies from Russia, France, Switzerland, and the United States. Qu'en pensez-vous?

There are two other sea-bathing places on the Straits of Dover which I need say but few words about—Calais and Dover.

No one, I presume, would by choice reside for long in either of these towns. Calais is one of the most miserable towns I know, and I never pass through it without longing to throw down its ugly walls and let in fresh air and sunshine into its poor, filthy, narrow streets.

Dover, again, has but one great attraction, its pier; but, otherwise, I certainly cannot think that it can be spoken of as a thoroughly healthy residence for an invalid. The town is at the bottom of steep cliffs, and, except by the sea, is nearly inaccessible to the fresh breezes. It is greatly composed, too, of shops and taverns for the sale of spirituous liquors to the numerous vessels which enter the harbour of refuge.

I returned, therefore, to Folkestone, as the true health-resort of the Straits of Dover, and cannot help thinking that invalids and over-worked citizens of London or other large cities would find here all that a sea-bathing place ought to offer—pure air, pure sea-water, music, tranquillity, and comfort.

I remain, Sir, yours, &c.,  
HYGIENE.

Folkestone, August, 1874.

## Medical News.

**Apothecaries' Hall of London.**—The following gentlemen passed their examination in the Science and Practice of Medicine on the 24th inst., and received certificates to practise:—Messrs. John Duncombe Bell, Antigua, West Indies, of St. Bartholomew's Hospital; Thomas Gallimore, of the Manchester School of Medicine; William Doidge Haslam, M.R.C.S.E., of University College, London; Alfred Steward, L.R.C.P. Edin., M.R.C.S.E., of the School of Medicine, Manchester; and John Binns Southam, M.R.C.S.E., of the School of Medicine, Manchester. On the same day, John Hague Clegg, student of St. Bartholomew's Hospital; Edward George Dutton, student of Guy's Hospital; and Alexander Thomas Scott, student of the Middlesex Hospital, passed their primary professional examination.

**Removal of Lunatics.**—The relieving officers for the parish of Shoreditch have called the attention of the guardians of the poor to the want of room in the asylums for lunatics in the London district. The relieving officers are liable to a penalty of £10 when a lunatic is kept longer than ten days in the workhouse, and when patients are sent to asylums at a distance, such as Fisherton House, near Salisbury, the relatives of the lunatics complain of their being sent to such a distance, as it precluded their visiting them. Mr. Charles Stevens, the Chairman of the Board of Guardians, thereupon moved, and it was unanimously resolved—"That, in the opinion of the Board, it is absurd, extravagant, and cruel to send these lunatics so far away as Salisbury." Mr. Parker, the clerk to the guardians, was instructed to forward a copy of this resolution to the Commissioners in Lunacy, and at the meeting of the guardians held last week an answer was received from the Commissioners in Lunacy acknowledging the receipt of the letter and the extract from the minutes of the guardians, and stating—"The Commissioners of Lunacy fully concur in the view taken by the guardians of the hardship of removing insane paupers to a distance from their relatives, and one of their number especially alluded to the subject in his report of a visit made to the Shoreditch Workhouse December, in 1870; but the county authorities having failed to make proper provision, it does not appear that any other course is open than that of sending urgent cases to the newest establishment at which they can be received."

**Diseased Fish.**—At a meeting of the Court of Common Council, at Guildhall, on Thursday last, a discussion arose respecting a combination alleged to exist among the fish salesmen to prevent a certain portion of fish coming to the London market until it is stale and useless. In the course of this discussion it was mentioned that during the last month the Fishmongers' Company had seized and destroyed at Billingsgate Market no less than 120 tons of fish as unfit for human food—a quantity sufficient to supply the whole of London for an entire week. When it is remembered that, besides the 120 tons of fish, countless other tons of all kinds of food really "unfit for human consumption" have probably found their way down the throats of the public during the period referred to, it will be seen at once that our powers of digestion are, like our supplies of unwholesome food, practically illimitable. Diseased meat, stale fish, and rotten fruit would not be offered for sale if they did not find a ready market, and it is the readiness of people to devour garbage that encourages the caterers for the public to keep up a constant supply of articles of this description. In food for the mind there is also to be observed the same absence of fastidiousness as in food for the body. Our cheap literature is much on a par with our cheap food, and is, moreover, as eagerly bought and devoured.

**Complaint against a Nurse.**—Clara Mauhwitt, a nurse at the Homerton Fever Hospital, was summoned to Worship Street for an alleged assault committed on a child named Florence Louisa Witherington. The father of the child said that his daughter was sent to the hospital suffering from scarlatina. She died there, and when he saw her body he saw that her throat was cut in three places. Before her death she had complained to him that the night nurse had beaten her, and she had a black eye, which witness saw. He had written to the coroner for an inquest, but the coroner had refused to hold one. He had applied to the hospital manager for an inquiry, but had been told that he could go away and feel satisfied that his child had been

kindly treated. Mr. Ricketts said that he had a letter from the coroner for the district which quite negated the assertion of the complainant that an inquest was refused. The medical officer reported that, beyond the statement of the child herself, he was unable to find the slightest foundation for supposing that the child had been maltreated. He thought that her complaint might have arisen from the fact that, as she refused her medicine, some force was necessary to get her to swallow it. Dr. Collie also reported to the Local Government Board that he found no ground for the complaint, and expressed his opinion that the defendant was a valuable nurse, and that the charge owed its existence to a system of persecution towards her. Mr. Flowers said that he had allowed the inquiry to go on, rather out of order only out of respect for complainant's feelings as a father, as he thought some assault had been committed on his dead child. But he was satisfied that the child had been thoroughly well treated, and, in dismissing the summons, he said that there was not the slightest stain on defendant's character.

## Cleanings.

**Some Inquiries into the Causes of Goitre, and Circumstances under which Cretinism is developed.**

By J. B. WILSON, M.D., Surgeon to the 11th Prince Albert's own Hussars.

(From *The Indian Annals of Medical Science*, No. XXXII.)

BHAGSOO, Dhurmsala, a hill station of the Punjab for British troops, is situated upon a spur of one of the lower ranges of the Himalayan mountains, at a height of about 6,100 feet above the sea-level, in a position of about 78° longitude, and 32° north latitude.

The whole district is hilly; we look below upon the Kangra valley, which stretches from east to west, and is in this neighbourhood about 3,000 feet above the sea-level; we see above in a north-easterly direction successive ranges of the Himalayan mountains varying in height from 10,000 to 18,000 feet. The highest range visible, which bounds us on the north at a distance of about 6 miles, is of primary formation, and consists of granite and gneiss. Except when covered with snow, as it is during the greater part of the year, this range is quite bare, no soil resting upon its stony surfaces. The lower hills, immediately beneath and intervening between the main visible range and this station, are for the most part of sandstone of varying degrees of hardness, and are covered with soil and vegetation, chiefly Himalayan oaks, rhododendrons, and fir trees. The valleys between these hills are rich in deep alluvial soil, largely mixed with pulverised stone. Through the sandstone hills, which are chiefly formed of rich red clay, overlaid with a vegetable mould, are numerous extensive veins of marble-veined limestone, and valuable seams of fine slate, and these stretch to the Kangra valley, below which, at a radiating distance of about ten miles, is the local boundary point in that direction of the present investigation. (a)

The primary source of the water supply is the main visible range; it finds its way to the valleys by streams, whose beds are cut out of, and seen in great numbers along the slopes of the successive hills already referred to.

Amongst the native inhabitants of this district "goitre" abounds. The remark of Dr. Parkes in his manual "that there is want of chemical analysis" in support of the hypothesis that there is no relation between the hardness of water and goitre prompted me, with such unusual opportunities for making investigations in this important and interesting subject at hand, to analyse specimens of the drinking-water obtained from this district within a radius of ten miles.

The preliminary examination of the first six specimens gave negative results, when testing for organic matter, lime, magnesia, iron, &c., and the colour, taste, and smell also indicated more than usual purity; with the object in view, I considered that these results dispensed with further examination except to determine the total hardness of each specimen.

(a) I have to thank the Rev. J. H. Hocking for some geological information concerning this district.

The preliminary examination of the last three specimens indicated a small amount of lime, confirmed afterwards by the soap-test. The colour, taste, and smell indicated purity of the specimens, and there was no reaction produced when testing for organic matter.

TABLE OF CHEMICAL ANALYSIS OF WATER.

No.	Date.	Description.	Source.	Result.
1	1873. July 3	Snow water	From a distance of about 10,000 feet above sea level.	1.73 grs. of total solids per gallon of Clarke's scale.
2	„ 3	Stream ditto	Collected in Bhagsoo.	4.45 grs. do.
3	„ 29	Ditto.....	Procured at Bhagsoo after filtration.	3.5 grs. do.
4	„ 30	Ditto.....	From Seco, a village about 2,500 feet above the sea level, and 7 miles distant.	5.25 grs. do.
5	„ 30	Spring ditto	From a spring at Dhur, a village about 3,000 feet above the sea level, and 5 miles distant.	2.8 grs. do.
6	„ 30	Stream ditto	From Chatroo, a village about 2,500 feet above the sea level, and 6 miles distant.	6.30 grs. do.
7	Sep. 25	Spring ditto	From Grow, a village about 5 miles distant, and 3,000 feet above sea level.	13.3 grs. do.
8	„	Ditto.....	Ditto.....	9.1 grs. do.
9	„	Ditto.....	Ditto.....	10.5 grs. do.

I have also to submit the analyses of 100 cases of goitre, taken indiscriminately from amongst natives residing within a radius of ten miles from this place, with regard to the following points:—

## 1st.—Occupation.

Labourers ...	52
Shoemakers ...	9
Musicians ...	9
Cloth-printers ...	6
Beggars ...	4
Glass-blowers ...	3
Bread-makers ...	3
Silversmiths ...	2
Merchants ...	2
No occupation ...	2
Policeman ...	1
Barber ...	1
Basket-maker ...	1
Carpenter ...	1
Overseer ...	1
Butcher ...	1
Housewives (a) ...	2

100

(a) There were altogether eight females; but when pursuing occupations, they were returned accordingly in the list with the males.

2nd.—The average number of pulsations per minute of the 100 cases examined, arranged according to the following ages:—

Between the ages of 7 and 10 there were 3 cases, and the average radial pulsation per minute was 101½.

Between the ages of 11 and 20 there were 26 cases, and the average radial pulsation per minute was 93½.

Between the ages of 21 and 30 there were 47 cases, and the average radial pulsation per minute was 86½.

Between the ages of 31 and 40 there were 14 cases, and the average radial pulsation per minute was 84½.

Between the ages of 41 and 50 there were 4 cases, and the average radial pulsation per minute was 84.

Between the ages of 51 and 60 there were 4 cases, and the average radial pulsation per minute was 92. (a)

Between the ages of 61 and 80 there were 2 cases, and the average radial pulsation per minute was 70.

3rd.—The time of life that the disease made its appearance:—

In 30 cases it appeared during infancy and childhood.

In 42 cases it appeared between the ages of 10 and 20 years.

In 17 cases it appeared between the ages of 21 and 30 years.

In 6 cases it appeared between the ages of 31 and 40 years.

In 4 cases it appeared between the ages of 41 and 50 years.

In 1 case the time of appearance was not known.

4th.—Concerning the transmission of the disease from one parent, or both, to offspring:—

(a) In 16 cases the parents, one or both, had been the subjects of goitre.

(b) In 9 of these cases the subjects were of dull intellect; in some cases approaching cretinism.

(c) In 4 of these the subjects were complete cretins. (In 2 of these cases it was stated that the mothers had very large goitres.)

(d) In 3 of these the subjects were not of dull intellect.

(e) There were 5 cases of dull intellect in which neither parent had suffered from goitre.

The results of the chemical analysis seem to strengthen the theory that it is not absolutely necessary for people to drink hard water before they can become affected with ordinary goitre; indeed, the extreme purity of some of the specimens examined, and which are and have been daily consumed by these goitrous people for years, leads one to conclude that the disease is not connected with the composition of the water at all.

The classification of the cases according to occupation shows an excess of the disease to occur amongst those whose daily duties are most laborious; for we see 52 per cent. of the subjects of it to be labourers.

It will be well to define the term "labourer" or "cooly" as it is applied in this classification. His duties are either to carry heavy loads strung upon his shoulders and back, or in company with others, to carry for long distances in a dooly (an eastern conveyance borne by men) European passengers.

The labourer or cooly in this district is often employed in carrying and cutting stones, building walls, and cultivating land. I wish to mention the attitude that he assumes when engaged in any occupation of this kind. He is rarely seen in the erect posture unless conveying loads; all other duties he pursues in a position that is peculiar to eastern countries.

The soles of his feet rest upon the ground, and the *nates* are brought into close proximity to the heels, by the thighs being flexed on the body, and the calves of the legs being applied to the posterior surface of the thighs. In this position also the shoemaker and other artisans pursue their work, for chairs and stools are never employed by them, even when at rest. With regard to the time of life that the disease usually appears, it will be seen that in 42 per cent. of the cases it first made its appearance between the ages of 10 and 20—a period including the time of life when active labour is first pursued; also the era of life when the constitution receives the new impulse and modification of puberty. The time of life that I found next in order susceptible to the disease was the unresisting period of infancy and childhood.

(a) In one of these cases the pulse was 100, in another 92, per minute.

It will be seen from the classification of the frequency of the arterial pulsation, that the average results of the cases registered according to age invariably showed a marked excess in frequency. There is great difficulty in obtaining precise information from a native, but when it could be obtained, I always found that the subjects of goitre were liable to palpitation of the heart.

This associated condition I invariably found amongst Europeans here resident who were the subjects of ordinary goitre. As far as it goes, the last classification shows a tendency for a degenerate form of intellect to be present in the offspring of goitrous parents, and that cretinism does not exist except in the offspring of parents who are the subjects of this disease. Before I venture to submit some conclusions and facts in support of them, based upon these investigations, I must mention the very universal frequency of this disease in hilly and mountainous districts. The purity of the water consumed by the inhabitants of this district amongst whom goitre has existed so long, and is daily reappearing, naturally leads one to conclude that the disease is not connected with the composition of the water at all. There is strong evidence in favour of the theory that ordinary goitre, like the exophthalmic variety, is entirely a circulatory disease, and that its tendency to occur is encouraged, and in some cases induced by the following conditions when the constitution is in a reduced state, and thus favourable to the invasion of this disease:—

1st.—Active occupation, necessarily so much more severe in hilly districts, seems to influence the production of this disease to a great extent, as is shown by its so frequent occurrence in those who lead a laborious life, or pursue active duties in a constrained position, and by the comparative immunity there is in those oppositely circumstanced, except they are in a relaxed and depressed state of health. The effects of violent exercise upon the circulation and blood-vessels generally are well-known, and it is only necessary, on this point, to refer to the relation of the thyroid gland to the large vessels of the heart, its remarkably large supply from them, and its dense capillary structure and consequent ready liability to enlargement from the dilatation of its vessels, under the conditions produced by violent and prolonged exercise.

2nd.—The effect of elevation from the sea-level upon the circulation of people residing in high mountainous districts seems to be favourable to the production of goitre, and in some cases the chief cause of the disease; hence the more frequent occurrence of the disease in such districts. The frequent complaints of people after arriving from the plains at a high elevation, of palpitation, sense of giddiness, the frequent bleeding at the nose, and the invariable increase of the frequency of the pulse, are all symptoms which point to a diminution of force upon the balance of the circulation as the cause of them. Nor is the loss of balance difficult to account for, when we remember that at the sea-level there is a pressure of 15lbs. on the square inch, and, calculating that the atmosphere reaches 45 miles around the earth, the loss of pressure resulting from this elevation would be equal to about 6·06oz. avoirdupois on the square inch, or a little more than one ounce less of pressure on each square inch of the body per every thousand feet ascended. The pressure would be a little less, though, for this calculation, contrary to accepted facts, supposes the 45 miles of air to be of uniform density.

The increase of force the circulation would receive by the diminution of atmospheric pressure, resulting from ascent within the limits of a certain height, cannot then, I think, be denied. I will relate some cases in which the disease seems markedly to have been produced by residence in elevated locality alone.

Mrs. S—, in November 1866, went to reside in Mussoorie, a hill station of Bengal, between 6,000 and 7,000 feet above the sea-level, and remained there until November 1867. In the month of July 1867, during some slight indisposition, a goitre appeared; it was about the size of a large walnut. It did not increase in size at all, but continued that size until Mrs. S— went down to the plains again. She remained in the plains until August 1873, and during the whole time no more enlargement of the gland was noticed by her. She visited this station in August 1873, and before she had resided here a month, found that the gland was rapidly getting bigger. It is now (September 1873) the size of a small apple, and rather painful. She is subject to attacks of intermittent fever; she is now free from the fever, but the pulse is 108 per minute, and she often suffers from palpitation. There is no exophthalmic appearance.

Mrs. B—, a sergeant's wife, states that, in 1860,

when she was aged 8 years, she went from the plains to Sinawur Lawrence Military Asylum, a sanitarium situated about 6,000 feet above the level of the sea. Before she had resided there a year a small goitre appeared, and has remained the same size ever since. She herself says that she is quite well, the pulse is 100 per minute, and she often suffers from palpitation. There is no exophthalmic appearance. At this Asylum every precaution was taken with the water, which was always boiled and filtered before use.

Juhar, a labourer, aged 25 years, came from Grow to Dhurmsala one-half years ago; there is a difference in the height of about 3,000 feet between these places, the latter being the higher. After arriving he took to new employment, much more laborious than that he had pursued below. After a residence of six months, the goitre first appeared.

Grousam, a beggar, aged 50, first came to this district from the plains eight years ago; shortly after his arrival the goitre began to appear.

3rd.—The increased frequency of the circulation invariably noticed in the subjects of this disease is further evidence of its resulting chiefly from a more active force conveyed to the circulation and so to the thyroid gland, when the resistance necessary to overcome that force does not exist in it; in a similar way, as in one subject aneurism takes place as the result of violent exercise, or from constrained positions, or, as in another, enlargement of the spleen, when subjected to a determination of blood, may take place.

4th.—The fact that the periods of life when this disease most frequently occurs are those when the circulatory powers are in their greatest activity is not, I think, of trivial import in support of the theory here submitted as the primary cause. There is the testimony too that, when the forces upon the circulation resulting from violent exercise in hilly districts and residence at a great elevation from the sea-level appear to be the chief causes necessary for the production of this disease, those engaged in the more active life are the more subject to it, viz., the male population; whilst in my experience concerning the occurrence of the disease in the plains, where it is of infinitely less frequent occurrence, the subjects more liable to it are females, whose constitutions are usually more relaxed and unresisting than those of males, and whose circulation, moreover, is subject to more variation of force, consequent upon the changing phenomena of menstruation and pregnancy.

5th.—If the conclusions arrived at from these inquiries into a limited number of cases hold good generally, the prevalence of this disease once recorded to have taken place in a prison at home, may have arisen not from the water that the prisoners drank, and which was blamed as the cause, but from the excessive exercise at the treadmill, or some other violent labor, and this, too, whilst the inmates were on prison rations.

In conclusion, and with regard to cretinism, the question naturally arises, whether it is found to be generated only in the offspring of goitrous parents, under which circumstances it has invariably been found to occur amongst the subjects of it in the cases of goitre, forming the subject of the present paper.

## NOTICES TO CORRESPONDENTS.

**✍ CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

If Dr. Boyd Mushet will send his MS. it will be returned to him if not approved.

**PODALIRIUS** will find his letter with reply in the *Journal of the Irish Medical Association*.

**NO ACCOUNTING FOR TASTE.**—The latest American story, remarks the *Observer*, is of a young lady who had an extraordinary taste for clay, which she ate in great quantities. Of late her general behaviour had been rather strange, and she frequently said that she felt as if she could take wings and fly. The other day she rushed out of the house, flapped her arms as though they were wings, sprang ten feet in the air, and fell to the ground dead. A post-mortem examination showed that she was swarming with grasshoppers, and the conjecture is that their desire to migrate with their fellows led to the girl's eccentric conduct.

The young lady's name is set down as Boomshine, possibly a misprint for "moonshine."

AN AMERICAN SURGEON will find an answer to his inquiry upon the front page of advertisement columns.

THE PROFESSION IN EUROPE.—The *Golos* of St. Petersburg states that in Russia there is but one physician to every 17,800 souls. There are governments, such as that of Perm, circles like that of Sherdink, where the proportion is still smaller, and there is scarcely one physician to 60,000 souls. There is, moreover, one hospital to every 175,000 inhabitants; one for women in labour to every 6,000,000; one for foundlings to every 1,350,000; one lunatic asylum to every 390,000; one deaf and dumb institution to every 11,000,000. The Russian journal says that the army is better provided for, there being one hospital to every 5,000 men. In Prussia the proportion is one to 1,250; in Italy there is one physician to every 2,280 inhabitants; in England there is one medical man (surgeons included) to every 3,180.

Dr. BARTLE will please receive our thanks.

SUSCRAINER.—The appointment is in the hands of Colonel Stewart Wood, the Inspector-General. The dispensary medical officer is always chosen, if there be no one else previously in possession; but the Inspector-General will not—and we think very properly—oust an efficient officer for the purpose of giving the office to the dispensary medical officer. We state this from our knowledge of the course pursued under similar circumstances, not from any direct official information on the subject. The Inspector-General's office at Dublin Castle is a type of the Jack-in-office style of doing business, in which the affairs of the public should not be transacted. The officials of the R. I. C. office seem to think that impertinence to the public is the fashion in military quarters, and as they inspire to ape the soldier in this and all other matters, nothing but an ungentlemanlike snarl can be elicited from them in response to inquiries.—Ed. M. P. & C.

THE case of "Strangulated Inguinal Hernia" reported in our last issue was under the care of Dr. W. H. Middleton, in the Westmeath County Infirmary. The revised proof, in which the author's name appeared, did not reach us in time to enable us to correct the omission.

#### VACANCIES.

Stranorlar Union Dispensary District. Medical Officer. Salary, £100 per annum, exclusive of fees. Applications to be addressed to Mr. Gunning, Hon. Sec. (See Advt.)

University College, London. Professorship of Comparative Anatomy and Zoology. Full information of Mr. Robson, at the College.

St. Marylebone, London. Medical Officer for the Christ Church District. Salary, £230 per annum. Application to be made to the Clerk, at the Union Office.

Queen's Hospital, Birmingham. House Surgeonships. Salary, £50 per annum, with board and residence. Address the Secretary.

Bedford General Infirmary. House Surgeon. Salary, £100 per annum, with board and residence. Testimonials to the Chairman of Committee.

Three Counties Pauper Lunatic Asylum. Resident Medical Superintendent. Salary, £600, with furnished house. Applications to the Clerk of Committee, St. Neots, Hunts.

Lutterworth Union. Medical Officer. Salary, £104 per annum for the District, and £30 for the Workhouse. Apply to the Clerk of the Union.

Ripon Dispensary. Resident Medical Officer. Salary, £100 per annum. Full particulars of the Hon. Sec.

Liverpool Dispensary. Assistant House Surgeon. Commencing salary at £108 per annum, with apartments. Address the Secretary.

St. Mary's Hospital, Manchester. Medical Officer. Salary, £60 per annum, with board and residence. Applications to the Secretary.

Kent. Public Analyst. Remuneration by fees. Address the Clerk of the Peace, Maidstone.

Manchester, Owens College. Lectureship on Chemistry. Mr. Nicolson will supply full particulars.

Westminster Hospital. Physician and Assistant Physician. Honorary election on the 23rd prox. Testimonials to be sent in by the 15th. Brompton Consumption Hospital. Resident Clinical Assistant.

Hospital for Stone, London. House Surgeon. Salary, £50 per annum. Apply to the Secretary.

Hospital for Women, London. Dispenser. Particulars of the Secretary.

Woolwich Union, Kent. Dispenser for the Infirmary at Plumstead. Salary, £60 per annum. Applications to the Clerk of the Union, Plumstead.

#### APPOINTMENTS.

ASH, Dr. L., Medical Officer of Health for the Rural Sanitary District of Hol-worthy, Devonshire.

BAKER, E. L., L.R.C.S. Ed., Resident Medical Officer to the York Dispensary.

CHAPMAN, F. R., M.B., C.M., House Surgeon to the Hull and Southcoates Dispensary.

COTTON, H. J., M.B., C.M., M.R.C.S.E., a House Surgeon to the Edinburgh Royal Maternity Hospital.

DAVIES, W. M., M.B., C.M., L.R.C.P. Ed., a Medical Officer to the County Hospital, Huntingdon.

DAVIES, H. A., M.D., C.M., Medical Officer, Public Vaccinator, and Registrar of Births, &c., for the Newport Dispensary District and Workhouse, co. Mayo.

DITTMAR, W., F.R.S.E., Professor of Chemistry at Anderson's University, Glasgow.

FOTHERGILL, J. M., M.D., Junior Physician to the West London Hospital, Hammersmith.

HARVEY, C. A., M.D., L.A.H. Dub., Resident Apothecary and House Surgeon to the South Charitable Infirmary and County Hospital, Cork.

HEDLEY, J., M.R.C.S.E., a Medical Officer to the North Riding Infirmary, Middlesborough.

HESSEGRAVE, J., M.R.C.S.E., Medical Officer of Health for the combined Golcar, Linthwaite, Longwood, Marsden, Scammonden, and Slaithwaite Urban Sanitary Districts.

HOURIGAN, W. P., M.D., Medical Officer and Public Vaccinator for the Tullaroan Dispensary District of the Kilkenny Union.

KENNEDY, D. A., M.D., Medical Officer to the Liverpool North Dispensary.

LAMB, J., M.R.C.S.E., a Medical Officer to the B'kenhead Ladies' Charitable Institution and Lying-in Hospital.

LEYS, P., M.B., C.M., House Surgeon to the Perth City and County Hospital.

LONGOTHAM, G., M.R.C.S.E., a Medical Officer to the North Riding Infirmary, Middlesborough.

M'CREEERY, J. O., L.R.C.S.I., Medical Officer and Public Vaccinator for the Missenden District of the Amersham Union.

RADAGLIATI, A. C. F., M.D., L.R.C.S. Ed., Assistant Surgeon to the Bradford Eye and Ear Hospital.

ROE, R. G., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer, Public Vaccinator, and Registrar of Births, &c., for the Ballyroy Dispensary District of the Newport Union, co. Mayo.

SCOTT, H. M., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer, Public Vaccinator, and Registrar of Births, &c., for the Achill Dispensary District of the Newport Union, co. Mayo.

TREVES, W. K., F.R.C.S.E., Medical Officer of Health for the Margate Urban Sanitary District.

WEST, R. E., M.R.C.S.E., Medical Officer of Health for the Tavistock Rural Sanitary District.

WILLIAMS, W. E., M.R.C.S.E., Medical Officer of Health for the Bed-welly Rural Sanitary District.

#### Marriages.

BARTLETT—MILLS.—On the 22nd inst., at St. Mary Magdalen Church, St. Leonard's-on-Sea, James Prime Bartlett, late Resident House Surgeon to the Brompton Consumption Hospital, to Amy Emmeline Strange, eldest daughter of J. H. Mills, Esq., of Stratford Place, Camden Square.

HERON—EVANS.—On the 17th inst., at the British Consulate, Frankfurt, G. Allan Heron, M.D., of Glasgow, to Harriett Maria, only surviving daughter of the late Charles Evans, Esq.

PHILPOTS—JONES.—On the 17th inst., at St. Mary's Church, Longfleet, Dorset, John Richard Philpots, L.R.C.P. Ed., L.R.C.S. Ed., of Moorcroft, to Lily Mary, of Parkstone, younger daughter of K. W. H. Jones, Esq.

THOMPSON—NICHOLLS.—On the 24th inst., at St. Luke's, West Holloway, William Allin Thompson, Surgeon, of Oxford, to Laura Catharine, eldest daughter of Francis Nicholls, of Hillmartin Road, West Holloway.

#### Deaths.

FALCONER.—On the 15th September, at St. Anne's, Laswade, John Falconer, Surgeon, late of Loanhead, aged 67.

HICKSON.—On the 6th September, at Mersey Road, Rock Ferry, Robt. Hickson, M.D., aged 82.

HOADLEY.—On the 2nd April, at sea, on board the ship *Stonehouse*, Mary Anna, the beloved wife of Robert Hoadley, M.D., late of Auckland Lodge, Fulham. Also on the 6th May, their infant daughter.

MACKENZIE.—On the 19th September, at Upper Woburn Place, P. M. Mackenzie, M.D., Member of the Legislative Council of the Island of Tobago, aged 53.

ROBSON.—On the 21st September, at Iver, Bucks, F. A. H. Robson, Esq., M.D., F.R.C.S.

ROE.—On the 17th September, J. R. Roe, L.R.C.P.E., of Br. d'gnorth, Salop.

STOKES.—On the 18th September, John F. Stokes, L.R.C.P. Ed., of Brook Road, Bootle, aged 26.

**ST. THOMAS'S HOSPITAL, ALBERT EMBANKMENT, WESTMINSTER BRIDGE, S.E.**

The MEDICAL SESSION for 1874 and 1875, will commence on THURSDAY, the 1st OCTOBER, 1874, on which occasion an ADDRESS will be delivered by Mr. MACCORMAC, at Two o'clock.

Gentlemen entering have the option of paying £40 for the first year, a similar sum for the second, £20 for the third, and £10 for each succeeding year; or, by paying £105 at once, of becoming perpetual Students.

Private Classes for Students preparing for Matriculation, and for the Preliminary Scientific Examination of the University of London, or for other Examinations, are conducted by members of the Staff, and embrace instruction in Chemistry, Natural Philosophy, Botany, and Comparative Anatomy. These Classes can be attended without entering at the Hospital.

**PRIZES AND APPOINTMENTS FOR THE SESSION.**

THE WM. TITE SCHOLARSHIP, founded by the late Sir WM. TITE, C.B., M.P., F.R.S., the proceeds of £1,000 Consols, tenable for three years.

First Year's Student's. WINTER PRIZES—£20, £15, and £10. SUMMER PRIZES—£15, £10, and £5.

Second Year's Students. WINTER PRIZES—£20, £15, and £10. SUMMER PRIZES—£15, £10 and £5. The DRESSERSHIPS, and the CLINICAL and OBSTETRIC CLERKSHIPS.

Third Year's Students. WINTER PRIZES—£20, £15, and £10. Mr. GEORGE VAUGHAN'S CHESELDEN MEDAL. THE TREASURER'S GOLD MEDAL. THE GRAINGER TESTIMONIAL PRIZE. THE TWO HOUSE PHYSICIANSHIPS. THE TWO HOUSE SURGEONCIES. THE RESIDENT ACCOUCHERSHIPS. TWO MEDICAL REGISTRARSHIPS, at a Salary of £40 each, are awarded to Third and Fourth year's Students, according to merit.

THE SOLLY MEDAL, with a Prize of at least 10 Guineas, will be awarded at the end of the Session, to a Student of the Third, Fourth, Fifth, or Sixth years, for the best Report of Surgical Cases.

**MEDICAL OFFICERS.**

HONORARY CONSULTING PHYSICIANS.—Dr. Barker and Dr. J. Risdon Bennett.

HONORARY CONSULTING SURGEON.—Mr. Frederick Le Gros Clark.

PHYSICIANS.—Dr. Peacock, Dr. Bristowe, Dr. Clapton, Dr. Murchison.

OBSTETRIC PHYSICIAN.—Dr. Barnes.

SURGEONS.—Mr. Simon, Mr. Sydney Jones, Mr. Croft, Mr. MacCormac.

OPHTHALMIC SURGEON.—Mr. Liebreich.

ASSISTANT PHYSICIANS.—Dr. Stone, Dr. Ord, Dr. J. Harley, Dr. Payne.

ASSISTANT OBSTETRIC PHYSICIAN.—Dr. Gervis.

ASSISTANT SURGEONS.—Mr. F. Mason, Mr. Hy. Arnott, Mr. W. W. Wagstaffe.

DENTAL SURGEON.—Mr. J. W. Elliott.

ASSISTANT DENTAL SURGEON.—Mr. W. G. Ranger.

RESIDENT ASSISTANT PHYSICIAN.—Dr. Turner.

RESIDENT ASSISTANT SURGEON.—Mr. McKellar.

APOTHECARY.—Mr. R. W. Jones.

MEDICINE.—Dr. Peacock and Dr. Murchison. SURGERY.—Mr. Sydney Jones and Mr. MacCormac. GENERAL PATHOLOGY.—Dr. Bristowe. PHYSIOLOGY AND PRACTICAL PHYSIOLOGY.—Dr. Ord and Dr. John Harley. DESCRIPTIVE ANATOMY.—Mr. Francis Mason, and Mr. W. W. Wagstaffe. ANATOMY in the DISSECTING ROOM.—Anatomical Lecturers.—Mr. Rainey and Dr. W. Reid. PRACTICAL and MANIPULATIVE SURGERY.—Mr. Croft. CHEMISTRY and PRACTICAL CHEMISTRY.—Dr. A. J. Bernays. MIDWIFERY.—Dr. Barnes. PHYSICS and NATURAL PHILOSOPHY.—Dr. Stone. MATERIA MEDICA.—Dr. Payne. FORENSIC MEDICINE and HYGIENE.—Dr. Stone and Dr. Gervis. COMPARATIVE ANATOMY.—Mr. C. Stewart. OPHTHALMIC SURGERY.—Mr. Liebreich. BOTANY.—Mr. A. W. Bennett. DENTAL SURGERY.—Mr. J. W. Elliott. DEMONSTRATIONS MORBID ANATOMY.—Dr. Payne. MORBID ANATOMY and PRACTICAL PATHOLOGY.—Mr. H. Arnott. MENTAL DISEASE.—Dr. Wm. Rhys Williams.

T. B. PEACOCK, M.D., Dean. R. G. WHITFIELD, Medical Sec.  
Any further information required will be afforded by Mr. WHITFIELD.

**UNIVERSITY OF LONDON.—MATRICULATION and PRELIMINARY SCIENTIFIC EXAMINATIONS. SPECIAL CLASSES for these Examinations are held at ST. BARTHOLOMEW'S HOSPITAL.**

The Classes are not confined to Students of the Hospital.

A Class for the Matriculation Examination is held twice in each year, from October to January, and from March to June.

A Class for the Preliminary Scientific Examination is held from January to July.

For particulars, application may be made personally or by letter to the Warden of the College, St. Bartholomew's Hospital.

**ST. BARTHOLOMEW'S HOSPITAL and COLLEGE.—**

**SCHOLARSHIP in SCIENCE.** Two Scholarships in Science have been founded at St. Bartholomew's Hospital. 1. An Open Scholarship of the value of £100, tenable for one year, to be competed for in September. The subjects of examination are—Physics, Chemistry, Botany, and Zoology. The successful candidate will be required to enter at St. Bartholomew's Hospital in October next. 2. Preliminary Scientific Scholarship of the value of £50, tenable for one year, to be competed for in October next by Students of the Hospital of less than six months' standing. The subjects of examination are identical with those of the Open Scholarship. For further particulars and syllabus of subjects, application may be made, personally or by letter, to the Warden of the College, St. Bartholomew's Hospital.

**ST. BARTHOLOMEW'S HOSPITAL and COLLEGE.—**

The WINTER SESSION will begin on THURSDAY, October 1.

The Clinical Practice of the Hospital comprises a service of 710 Beds, inclusive of thirty-four Beds for Convalescents at Highgate.

Students can reside within the Hospital walls, subject to the College regulations.

For all particulars concerning either the Hospital or College, application may be made, personally or by letter, to the Resident Warden of the College.

A Handbook will be forwarded on application.

**ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—**

The WINTER SESSION will commence on THURSDAY, 1st OCTOBER, with an Introductory Address by Dr. Dickinson, at 4 p.m., in the Hospital.

The system of Clinical Teaching has been arranged so as to afford every student personal instruction in the wards from the Physicians and Surgeons themselves.

The courses of Lectures on Physiology and Surgery have been remodelled in conformity with the new regulations of the College of Surgeons.

Special departments have been organised for practical instruction in Midwifery, Ophthalmic Practice, Skin Diseases, Vaccination, and Dentistry. Lectures on Public Health are given by the Lecturer on Medicine.

Pathology, Morbid Anatomy, Psychological Medicine, and Comparative Anatomy are taught in distinct courses.

Instruction is given in all the special modes of medical and surgical investigation.

The following paid offices are offered for competition annually—viz., Obstetric Assistant, Curator of the Museum, Demonstrator of Anatomy, Medical and Surgical Registrars.

The House-Physicians and House-Surgeons are selected by merit from among the Perpetual Pupils without payment, board and lodging in the Hospital being provided at the expense of the Governors.

The Wm. Brown Exhibitions of £100 per annum, tenable for two years, and £40 per annum, tenable for three years; the Brackenbury Prizes of £35 each annually, are awarded, along with various other prizes, by competition among the students.

The prospectus may be obtained by application to the Secretary at the Hospital, and any further information will be given by Dr. Barclay, Treasurer, or Dr. Wadham, Dean of the Medical School, either personally or by letter.

**ST. GEORGE'S HOSPITAL was RE-OPENED for the**

reception of Patients on the 9th SEPTEMBER. A new Microscope Room for the instruction of Students in Practical Histology has been added to the School Buildings.

**TO MEDICAL MEN, DENTISTS, &c.—**

The Widow of a professional man wishes to let a Dining-room Floor (two reception rooms) in a superior house a few doors from Russell Square.—63 Guilford Street, London, W.C.

**WESTMINSTER HOSPITAL MEDICAL SCHOOL,**

Opposite WESTMINSTER ABBEY.—The SESSION 1874-5 will commence on THURSDAY, OCTOBER 1st, with an Introductory Lecture by Dr. POTTER. The Address will be followed by the Distribution of the Prizes, and a Conversation in the Board-room. The new Physiological Laboratory will be completed by October 1st.

The Examination for the Entrance Scholarship will be held on the 2nd and 3rd of October.

5th August, 1874. GEORGE COWELL, Dean.

**B R I S T O L M E D I C A L S C H O O L.**

The WINTER SESSION will commence on THURSDAY, October 1. Prospectuses may be obtained on application to

GEORGE F. BURDER, M.D., Hon. Sec. Medical School, Old Park, Bristol, August, 1874.

**THE LONDON HOSPITAL and MEDICAL COLLEGE.**

The next WINTER SESSION will commence on Thursday, October 1st, 1874, when the Introductory Lecture will be given at 3 p.m., by SAMUEL FENWICK, M.D., Assistant-Physician to the Hospital.

General Fee to Lectures and Hospital Practice, 90 guineas, payable in two instalments of 45 guineas each. Library Fee, £1 1s. Special entries can be made to Lectures or Practice.

The Hospital contains 600 beds. The In-patients during 1873 were 5,613, and the Out-patients 43,803; total, 49,421.

The Following Prizes and Appointments are offered, without any further payment, to Students paying the general fee of 90 guineas:—

Seven Scholarships to be offered for competition in the Winter Session:

1. A Scholarship of £30 to the Student of less than three months standing who passes in October the best examination in the subjects required at the Preliminary Examination.
2. A Scholarship of £20 to the Student of less than three months' standing placed second in the above examination.
3. A Scholarship of £20 in Human Anatomy for first year Students; to be awarded in April, 1875.
4. A Hospital Scholarship, value £25, in Anatomy, Physiology, and Chemistry, for first year and second year Students; to be awarded in April, 1875.
5. A Hospital Scholarship, value £20, for Clinical Medicine; to be awarded in April, 1875.
6. A Hospital Scholarship, value £20, for Clinical Surgery; to be awarded in April, 1875.
7. A Hospital Scholarship, value £20, for Clinical Obstetrics; to be awarded in April, 1875; and a Prize of £5 to the Student who has attended most Midwifery cases for the Hospital during the preceding twelve months.

The Duckworth Nelson Prize, value £10, for Practical Medicine and Surgery (Biennial), 1875.

Money Prizes to the value of £60 given annually by the House Committee for zeal in Dressing Out-patients and knowledge of Minor Surgery.

For particulars as to appointments, &c., see the Prospectus, which will be forwarded on application to the Bedell of the London Hospital Medical College, Turner Street, E.

Further information may also be obtained from Mr. JAMES E. ADAMS, Treasurer, 10 Finsbury Circus, E.C.; or Mr. WARREN TAY, Vice-Dean, at the Medical College.

## The Introductories.

### THE LONDON HOSPITAL.

Lecture delivered October 1st.

By SAMUEL FENWICK, M.D., F.R.C.P., Lecturer on Physiology to the Hospital.

GENTLEMEN,—I know few things more difficult than to give an introductory lecture. Whatever I could say about medical education has been so often repeated, and has been told so much better than I can hope to do it, that I have always shrunk from the performance of the task. But you may, then, fairly ask, Why have an introductory address at all? Why not let each lecturer give to his students such preliminary instructions as they may require? The best reason for retaining this time-honoured custom is, that many of those just commencing their studies are not only ignorant of all the sciences allied to medicine, but are unpractised even in the methods by which they can most successfully pursue them. Hitherto their education has been restricted to languages and other branches of knowledge only requiring a quick and retentive memory for their mastery, or they have been taught mathematics, in which truths are deduced from facts intuitively recognised by the mind. But in medical science the student has to make himself acquainted with the facts from which conclusions have been derived; he has to judge how far many of the inferences he is taught are justified by facts, and he has often to decide for himself between the claims of opposing theories. It is not, therefore, surprising that many who enter upon the study of medicine with a great reputation for intellectual ability obtained in other pursuits should fail to satisfy the expectation of their friends, while others who have been previously undistinguished for talent rise rapidly to eminence and renown. Such being the case, there is good reason we should attempt each year to lay before those who are entering on their professional career some remarks as to the best method of pursuing their medical studies. The term "medical studies" will no doubt suggest to the minds of most of my hearers the two or three

years during which they are compelled to attend certain courses of lectures with a view of obtaining their diploma. Many are in the habit of imagining themselves students only till they can obtain a licence for practice, and they suppose as soon as this is acquired all necessity for intellectual exertion has ceased. No opinion can be more unfounded. Gentlemen, you are now entering upon a career in which the necessity for the acquirement of scientific knowledge can only terminate when the career itself ceases. We can admit no distinction between the periods before and after passing an examination, excepting that in the former you are answerable for the extent and thoroughness of your professional information to your teachers and legal examiners, whilst in the latter you are responsible to every patient who may seek your aid, as well as to the Creator who has bestowed upon you the opportunities of gaining that knowledge that may enable you to confer health and happiness on your fellow-creatures. But if everyone has to remain a student through the whole of his professional life, it is evidently a matter of importance to determine what are the mental faculties he should especially cultivate in order to fit him for the performance of the duties which will devolve upon him. Now, all education has for its object either to store the mind with knowledge, or so to train and improve the mental faculties that the individual may more readily acquire knowledge for himself. The former of these may be effected by the teaching of others; the latter can only be accomplished by yourselves. It is, in fact, *self-education*. The knowledge you obtain for yourselves is not only more useful in its character than what you acquire from others, but, from its being more completely assimilated, it can be more readily turned to practical account. It is of self-education, or rather of the best method of conducting it in regard to medical science, that I intend to speak to you to-day. It consists in the constant employment of certain mental powers, so that they may be not only improved by exercise, but their use may become gradually strengthened into habits. When you remember that you are just at that period of life when habits of thought are most readily formed, and are most enduring, you will see that such a subject is of no small importance. The first

habit I would advise you to cultivate is that of minute and careful observation. When you look into the history of medicine you will see that all real progress has been made just in proportion as practitioners have founded their opinions on the close observation of disease. So long as they trusted to vague speculations upon pathological phenomena so long were their theories unsettled and their practice uncertain. But, you may say, what is easier than to observe correctly? why trouble ourselves to make it a habit? is anything more simple or easy than to follow the evidence of our senses? Unfortunately, history teaches us that men in all ages have neglected observation, or have allowed the plain evidence of their senses to be blinded by preconceived ideas. Let us look, for instance, at the simplest operation in surgery, the dressing of a wound. In the present day the youngest student will cleanse the wound, draw its edges together, and maintain them in contact, with a certain expectation of seeing the raw surfaces unite. Now, at all periods, the natural union of wounds must have presented itself to the most careless observer. Everyone must have seen how the injuries received by the lower animals are repaired; how the hair becomes mixed with blood and forms a means of uniting the edges, and how rapidly and completely a tear or cut becomes permanently closed. But in a warlike age, when all Europe was a camp, and when the slightest quarrel was settled by the sword, injuries were of constant occurrence, and we might suppose that the natural closing of a wound by adhesion must have forced itself upon the observation of everyone. Nevertheless, the surgeons of former days did not believe that wounds could heal of themselves. They held that every injury to the skin, however slight, must go through four distinct processes before it could unite. Under this impression they encouraged suppuration, cut off all loose flaps of skin without scruple, plugged wounds with tents of cloth or of metal, and dreaded above all things that simple and natural process of adhesion which we in the present day always encourage. To use the words of a well-known author, "surgeons looked upon surgery and cruelty as inseparable, and if a wound healed rapidly all subsequent ailments which might befall the patient were attributed to the mischance." Nor were these prejudices confined to the members of the profession; the public at large were imbued with the same idea. But, you will say, such ignorance could not last long. It would be so apparent that wounds could heal by adhesion that the strongest prejudice would be unable to prevent the acceptance of the fact. History tells us that men for a long period of time preferred to trust to authority rather than to observation, and that when a wound adhered it was attributed to some other agency than the operation of Nature: for example, we find Sir Kenelm Digby, Secretary to Charles I., writing a work in favour of the sympathetic treatment of wounds. He recommends that a piece of cloth dipped in the patient's blood should be placed in a solution and then carefully kept in a temperature the same as the human body, whilst the edges of the wound should be drawn together. In other cases the cure was said to be effected in the dry way. By this plan the weapon by which the injury had been inflicted was smeared over with a sympathetic ointment and suspended in a warm place until the cure was completed. After this there arose another method of treating wounds, named the secret dressing. The wounded part was sucked by the mouth of the operator, so that all blood and extraneous matters were removed, after which the edges were neatly drawn together and retained in position by bandages. The cure, however, was supposed to be effected, not by the closing of the wound, but by the grimaces of the operator, by signing the patient with the sign of the cross, and by an unintelligible jargon that was muttered over him. Now, during all this long period, while eminent surgeons were inventing medicines for the cure of wounds and philosophers were anointing the weapons by which the injuries were inflicted, men were so little accustomed to observe, or were so biased by prejudice, that they were willing to attribute their success to

any circumstance rather than that simple operation of Nature which was constantly taking place before their eyes. Many of you, no doubt, think it would be impossible for such ignorance to be persisted in in the present day. This is to a certain extent true, for we are now trained to regard observation as our guide. But I fear we have still many a wide-spread belief that rests rather on authority than observation, and that many a much-prized remedy, even now, is as powerless over the progress of disease as was the sympathetic powder in the healing of wounds. But it is easy to show I do not exaggerate the importance of observation, and the necessity that exists that you should keep yourselves clear of prejudice. Watch the action of your own minds, and you will see how much you dislike any subject that tends to unsettle your present opinions; how you wish to reject facts if they seem to run counter to your present conclusions; how unwilling you are to reopen subjects the discussion of which you believe to be definitely settled. Now, all science is progressive. What we regarded yesterday as a certain truth we have perhaps to doubt to-day, and to modify or reject to-morrow. Every fresh discovery but leads to another in advance, and unless you keep free from prejudice you will be liable to be left far behind in the progress of knowledge. The use of observation is to furnish facts from which conclusions may be drawn; but you must remember that, though your observation may be correct, your inferences may be wrong. Hence arises the necessity for testing them by experiment. In this method of investigation you can vary the conditions under which any particular fact may be observed, and by frequently altering the conditions you can often eliminate from the problem all sources of error, and thus ensure the accuracy of your conclusions. The history of medicine abounds with instances where unaided observations seemed to point at conclusions which subsequent experiments proved to be erroneous; a single example will be sufficient to convey my meaning: In the year 1786, a man one evening, shortly after his supper, received a severe injury on the skull. He was admitted into St. George's Hospital, and died in a few hours. The body was examined next day by John Hunter, who found to his great surprise that a large hole existed in the stomach, and the remains of his last meal had escaped into the peritoneal cavity. No mark of injury could be found likely to have caused the rupture, and the great physiologist was at first puzzled to account for such a circumstance. On thinking over the case, he remembered that the man had been killed whilst digestion was going on, and he was therefore led to suspect that the gastric juice had acted upon the stomach after death, and thus produced the opening which he had discovered. He examined every body brought into the dissecting-room that summer, and, after a series of experiments, he came to the conclusion that after death the gastric juice is capable of dissolving the organ by which it is secreted, although it is unable to act upon it during life. Considerable interest was excited by this discovery, but it was soon forgotten, more especially abroad, where men's minds were fiercely agitated by political occurrences. In the beginning of the present century great attention was bestowed in France on morbid anatomy. Pathologists were not a little surprised to find how frequently after death the stomach presented the appearance of softening. This took place in cases in which during life no symptoms had been observed pointing to disease of the stomach, and they were therefore led to infer that inflammatory softening of the organ was a frequent, insidious, and most fatal malady. Sir R. Carswell, who was then studying in Paris, was made acquainted with these facts, and remembering Hunter's observations, at once surmised that the so-called softening of the stomach was a mere post-mortem effect, and not the consequence of disease. He subjected the matter to the test of experiment. Two animals were killed during the process of digestion: the stomach of one was removed, and carefully washed, whilst that of the other was allowed to remain in the body filled with its contents. Both were examined two days afterwards; the stomach of the last

was found to be softened, and partially dissolved, whilst that of the former was perfectly natural. This, of course, settled the question, and explained the cause of the frequency with which the softening had been remarked. Now, you will observe that there was no fault in this case as regards the facts, but the inferences were incorrect, and a single experiment furnished a satisfactory explanation of an occurrence where unaided observation had only misled. But, on the other hand, it often happens that you are unable to draw any inference at all from your observations until you have explained them by experiments. No name stands higher in medicine than that of Laennec. By his great powers of observation and unrivalled acuteness he not only applied physical methods of diagnosis to the diseases of the lung, but he, in a great measure, exhausted the subject. He was less successful in respect to the heart. Notwithstanding that, he observed and described various murmurs that could be heard when the heart was in a diseased state; his conclusions as to their significance were erroneous. After his death the same confusion as regards the diagnosis of cardiac diseases continued. Amongst those who carefully studied the subject was Dr. Hope, and he was led to suspect that the sources of perplexity arose from an imperfect acquaintance with the causes of the normal sounds. He therefore planned and performed the following experiment: An animal was rapidly killed, and a pair of bellows fixed into the windpipe so as to keep up respiration, and therefore the action of the heart. On opening the chest both the sounds could be readily heard. A fine piece of curved wire was then passed into the artery so as to hook back the aortic valves: one of the sounds immediately ceased, but in its place was heard a loud hissing murmur, exactly similar to that which had so often puzzled the physician when listening to the chest of his patient. Thus a simple experiment cleared up the difficulty that had baffled even the industry and genius of Laennec; and there is now no part of physical diagnosis more easy to the youngest student than that of diseases of the heart. I have been thus particular in drawing your attention to the use of experiment because I believe it will in the future be one of the chief means of investigation. Let us look back at the history of medical science during the present century. Within the first thirty years there sprang up a school of earnest and enthusiastic workers in morbid anatomy. In every disease the condition of each organ was carefully scrutinised, and nothing can exceed the clearness and precision with which the coarser morbid changes were described. As a result of this knowledge, methods of physical investigation were invented by which their conditions could be accurately distinguished during the life of the patient; and to this school we owe the discovery of auscultation and the various other means of physical diagnosis. Within the second third of the century improvements in the microscope placed in the hands of anatomists a new instrument of research, which they were not slow to employ. Investigation was turned into a new channel, and the schools of North Germany replaced in fame those of Paris and Vienna. The discoveries then made seemed to have placed medicine upon a new basis, and vast were the expectations formed as to the future of medical science. Men attempted to base pathology upon cells, fibre, and granules, and hoped to distinguish disease by the microscopic characters of their products. But where do we now find ourselves in this last third of the century? We are no longer disputing as to the shapes and sizes of the various cells, or seeking for an explanation of cancer and tubercle in the forms of their cells, or the sizes of their nuclei. In morbid anatomy the harvest has been long since gathered in; we are now only gleaners in the field, just as in former times investigations in physiology followed hard upon discoveries in anatomy: so now the functional diseases of the organs are claiming the attention of those who have nearly completed their inquiries as to the structural alterations of the human frame. Still more pressing is the necessity of ascertaining what is the changes that occur in nutrition.

Look at the discussions in the medical societies during the past year; they are not upon matters of physical diagnosis, or on the changes in the shapes or sizes of organs, but our leading men are engaged in disputing as to the causes of blood diseases, such as pyæmia, or the nature of cancer and tubercle. And why do these discussions appear to have been so unprofitable? Simply because the various speakers have all been looking at the matters in dispute from an anatomical standpoint. They have been trusting to the microscope where new and improved methods of research are required. I believe that in the future, just as physiology was advanced by experiments and comparative anatomy, so questions in pathology will have to be settled by comparative pathology and by physical, chemical, and physiological experiments. But it is not only as a means of settling difficult and important points in pathology that experiment is useful; the necessity for it will continually force itself upon your notice. New remedies and new methods of treatment are daily brought forward; but how seldom are their merits fairly tested? They seem to be tried in a random way as soon as they are announced; but rarely is an attempt made to test them in such a manner as shall exclude as much as possible sources of error. The consequence is that an indiscriminate employment leads at first to exaggerated opinions as to their value, which is soon followed by disappointment, and often the remedy sinks into unmerited neglect. But there is a third habit, of the greatest importance, which you must carefully cultivate—that of recording your observations at the time they are made. Don't trust to your memory, or write your impressions when the mind has had time to think over and explain away a fact; but put it down at once, simply and truthfully. I have been often surprised how little medical students are in the habit of noting down their own observations. In every lecture-room they may be seen copying the opinions and remarks of their teachers; but how few seem to be aware of the importance of recording what they themselves witness in the wards, or in the post-mortem theatre. And yet a simple fact carefully and honestly noted may long after prove of incalculable value, although at the time it may have appeared to be of no great importance. This might be well illustrated by reference to the history of the discovery of anæsthetics. In 1799 Sir Humphrey Davy succeeded in procuring nitrous oxide gas in a state of greater purity than it had been before obtained, and he commenced a series of experiments with it upon himself. He found that, when taken into the lungs, instead of causing death, it excited a species of intoxication, during which insensibility to pain was one of the most prominent characters. In the next fifty years the exhibition of the effects of the nitrous oxide was a favourite experiment with popular lecturers on chemistry, and the original experiments and observations of Davy were generally known. No attempt was, however, made to employ it as a preventive to pain until 1844, when a Dr. Wells, of Hertford, in America, who was acquainted with Davy's observations, had a tooth removed whilst under the influence of the gas. The operation was performed without suffering, and the experiment was successfully repeated on some other persons. Shortly afterwards Dr. Morton introduced ether as a substitute for the gas. The results were most successful, and the employment of this liquid as an anæsthetic, thus commenced, was rapidly extended. But there were many objections to the ether, and other agents capable of producing similar effects were eagerly sought for. Sir James Simpson, of Edinburgh, substituted chloroform, which soon came into general use. A few years ago the method of preparing the nitrous oxide was again improved, and it is now universally employed in the extraction of teeth, and for other operations which can rapidly be performed. Now, what I want you to observe is, that this, which is perhaps the most valuable discovery ever made in medicine, was the result of observations noted down fifty years before. The experiments were performed with a totally different object in view,

and in all probability they would never have borne fruit had it not been for the careful record left us by their author. The value of recording observations at the time they are made is incidentally shown in the original paper of Sir Humphrey Davy. After the first experiment with the nitrous oxide he remarks: "The next morning the recollection of the effects of the gas was very indistinct, and had not the remarks written immediately after the experiment recalled them to my mind, I should have even questioned their reality." I would advise you, then, to make it a habit to note down the various facts presented to your notice. If you can collect a number of carefully recorded cases, you will find them invaluable for your present guidance, and your future reference. They will often lead you aright when you look in vain for help to the work of others. But in such records you must be careful to keep your minds free from preconceived ideas. Get a habit of marking down only what you see. Keep to the simplest language, and avoid all words that imply a theory. Carefully separate your conclusions from your observations. Subsequent experience may prove the former to be incorrect, but your facts will remain good, and may hereafter lead you to results of the greatest value. But, it may be said, the kind of education you have pointed out may be all very well for the pioneers of science; we have neither the time nor the inclination to be discoverers, but are content merely to practise what we have been taught. Believe me, gentlemen, every one engaged in our profession must be a discoverer as regards *himself*, although he may never communicate to the world at large what he has learned. Every case he sees enforces reflection, and either he is daily arriving at new truths, or his trust in his former beliefs is strengthened till it deepens into prejudice. You can change the properties of matter; you can compress gases into fluids, or fix them in a solid form: but you cannot crystallise mind. Your mental powers are in a state of ceaseless activity, and you can only fit them for the discovery of truth by following the same paths that were trodden by those who have attained to eminence before you. But many a young student will be apt to say, Is not the power of discovery the attribute of genius? How can we hope to tread in the steps of those who have left the impress of superior intellect on the history of science? Gentlemen, there is no greater mistake than to imagine that science owes her progress merely to men of great talents, or that those who have most deeply engraven their names upon her records have gained their distinction simply by the native grandeur of their intellectual conceptions. Amongst the Alpine peasantry there is a widespread superstition that figures of gigantic stature occasionally appear towering high above the clouds; travellers tell us that these so-called giants are no beings of another race, but men whose forms are magnified by the mists by which they are surrounded: so many of these great figures that look down upon us from the pinnacles of science were in their day but men of ordinary intellectual stature, but are magnified through the mists of the contemporary ignorance that enveloped them; They were men who, by patient toil and long persevering industry, scaled the heights of knowledge which others had not tried or dared to mount. But although you may lack originality, or the wish to advance the progress of science, you can, at any rate, imitate the qualities for which men of genius have been distinguished. Every man of scientific renown has exhibited great industry; without this all the genius in the world would be wasted. Aubrey tells us that the sons of Charles I. were committed to the care of Harvey at the battle of Edgehill, but that the great physician was so careful of his time that he was discovered reading a book while the action was going on. Hunter was the last to leave his museum at night, and commenced his labours in the early morning, long before any one else had left his bed. In addition to industry they have all possessed indomitable perseverance. Harvey remarks that, when he first began to study the action of the heart, it seemed to him so complicated that he thought none but God could comprehend it; and yet,

by constant perseverance, he succeeded in rendering this part of physiology so perfect that he left comparatively little for his successors to discover. Hunter used to say that he loved a great difficulty, because he knew he should make a great discovery. It is indeed strange how often we forget that all great works can only be produced by toil. When we look upon a work of art just unveiled before the public gaze we recognise not merely the genius that designed it, but the industry and perseverance of the sculptor in chiseling the solid marble into harmony with his conceptions. But when some great scientific discovery flashes before the eye we are apt to think only of the talents of the discoverer; we forget that equal labour and perseverance were required to bring it to perfection. I have been induced to lay before you the foregoing remarks because I believe it to be especially requisite in the present day to impress upon the mind of the student the necessity of self-education. Formerly too much attention was devoted to practical, too little to theoretical teaching. Now this is changed, and we seem to be passing into the opposite extreme. Numbers are entering the profession who seem to think that books and lectures can supply all the knowledge they need possess, and that to pass an examination with credit is the only aim of their student life. Believe me, gentlemen, books can never supply what can only be afforded by observation and experiment, and we can never by any examination test the acuteness of perception and the soundness of judgment that ought to characterise the physician, or the courage, coolness, and readiness of resource that are requisite for a surgeon. These can be only gained by patient observation and by long experience. It is in affording you a field for gaining these qualities that the London Hospital is especially valuable. Already one of the largest, it will, when its new wing is completed, be by far the greatest hospital in this country. The enormous number of accidents annually treated within its walls have long rendered it famous as a surgical school; whilst the nature of the population by which it is surrounded, the immense extent of the out-patient practice, and the number of special departments, will afford you opportunities for the study of medicine that can nowhere be surpassed. Gentlemen, many of us, teachers and learners, have met together for the first time; but, if you have not altogether missed my meaning, you will have gathered that we are all students alike, and that not one of us, however accomplished he may be, can claim to have finished his task. We indeed dimly discern, at best, many of the great laws by which things mental and corporeal are bound together, and we are often compelled to the utterance of Truth with stammering lips, or to follow her by devious paths and with faltering steps. Nevertheless, none of us, least of all, none of you now entering with enthusiasm on the work before you, will feel faint-hearted if you cast a backward glance at the history of our science and perceive the great progress it has made; you can rest your feet upon some great truths, and from these look forward with confidence to further progress: but, whether it be your lot to add to the number of these discoveries or not, the humblest amongst you cannot fail to fulfil a great and worthy purpose in life if he will honestly, patiently, and perseveringly strive to fit himself for the discharge of his duties in it.

### GUY'S HOSPITAL.

*Abstract of Introductory Lecture delivered October 1st.*

By SIR WM. GULL, Bart., M.D., F.R.C.P., &c.

BEFORE commencing his address the attendance was found to be so large that an adjournment from the hospital theatre to a larger hall, the Bridge House Hotel, had to be made. After a few introductory remarks, in the course of which he referred to his entrance as a student in Guy's Hospital thirty-seven years ago, the lecturer went on to observe that the study of medicine was like a man fettered. It ranged through human nature

in general. It looked at man in every aspect, and had the great collateral advantage for its followers that in pursuing it they were learning something of themselves. What this advantage was to them as medical students was not to be calculated if it duly impressed them with the fact that the laws of human health in its widest signification were part of the laws of moral and intellectual life; that indulgence, sloth, and vice were as contrary to our lower nature as they were to the higher laws within us. Their studies would, however, require constant mental direction. It was a common error with young students to think that it was only by some strong intellectual effort that good work could be done, whereas in truth it was more through patient and well-directed labour. If the first lesson were patience—a patience which knew how to wait, undismayed by what looked insuperable—the next lesson was docility—a readiness to learn at any source, not fastidiously or delicately, not where it might please us, but wherever the facts lie hid. The student's training of to-day must at every step be directed by the light and checks of science, and his acquirements must go hand in hand in the high mental culture which could alone enable him to apply his knowledge successfully. If in what had to be done mechanically technical rules for action could be given, it was not so when living processes had to be dealt with, for then there had to be exercised the power of judging of the value of the known as against the unknown. The voice of pure science would be for waiting for certain light; but suffering humanity had stronger claims, and could not wait; therefore was there necessity for a careful mental discipline. The medical profession stood almost alone in having to make the investigation of nature its prime duty. Others might labour in the same direction from a pure love of truth, or to relieve the tedium of life; but the medical student had and could not avoid the calls of duty to urge him to his work. He had to acquaint himself with the course of nature to the practical end of instituting a course of action under given circumstances. In the high object of medicine, however, did its greatest danger lie. The stimulus and the natural desire to act were mostly out of proportion to our knowledge and means for action. The motive to do something was but too apt to tempt to pretence of knowledge, which perverted the science and practice of medicine. The study of medicine was, said the lecturer, difficult to limit. The ancients called the human body the microcosm, and the outer world the macrocosm—in fact, one world within another. There were infinite and intimate relations between the two, and the whole art of medicine was to know and to act upon these relations, so as to favour what was favourable and exclude the contrary. The dogma that man's power and knowledge were limited by his observation of the course of nature could not be too plainly impressed upon the mind of the student of medicine. It was true we might and must believe and hope far beyond the boundaries thus prescribed, but belief and hope were but pioneers of knowledge, and where observation could lead the way there must be no halting in our steps to follow it. The expression "order of nature" indicated a rule which in one aspect was the most hard and inflexible. Amongst all the ever-changing phenomena of nature it asserted there was an unvarying oneness beneath. The variations in phenomena were but variations in combination or relations, but in the substratum itself there was no variation. The whole object of the science of medicine was based on this assumption. It was the whole purpose of our knowledge to find out and obviate what was inimical to our systems, and to discover and promote what was favourable. That, however, which would most occupy the time of the student in the hospital was the course of nature in disease. They would soon learn that diseases, like other natural facts, required no peculiar mode of study, although there was no doubt personal interest did much to hinder their due investigation and surround them with a mysteriousness which was not essentially belonging to them. Medicine had much advanced since she freed herself from the whole conception of diseases being independent entities, admitting of being labelled into orders and sub-orders; we were, however, not quite free from this, nor could definitions be avoided, although the aim of a good medical education was to teach the using of words and definitions but as a medium for arranging knowledge, not for confining it. After remarking upon the difficulties of attaining a good and correct mental training, and the various motives which should stimulate a medical man in the performances of his

duty, Sir W. Gull went on to say that there was sometimes an impression that medical men, being so largely occupied with the more fleeting phenomena of existence, and seeing more of the weakness than the strength of man, they were naturally led to ignore his higher nature and to regard him but as a very exquisite piece of material mechanism, and no more. He counselled them never to be satisfied with secondhand knowledge from books or lectures where it was within their power to get impressions from the objects themselves. The senses and the mind were active powers, which called for due objective exercises; medical study was a mere pretence without it. They did not come there as passive receptacles, to be filled with a complement of so-called knowledge which should fit them for asking questions. Happily, however, the times for this were changed. Examinations themselves were passing from the verbal to the objective stage, and nothing could supply the student with so practical a stimulus in the right direction as this change. But he would not say anything to lessen the value of lectures. Many of them were indispensable in demonstrating facts, the method of inquiry into them, and the result, while there was the teaching by personal influence, which was invaluable. As to books, the latest editions were for the most part to be read, as knowledge in every department was growing fast, and a book on physiology or the practice of medicine soon became obsolete, or ought to be so. Hospital reports, journals, and year books were invaluable. After referring to the importance of adding to our knowledge the use of instruments, the microscope, the thermometer, and the sphygmograph, &c., as aids to the senses, the lecturer went on to urge his hearers to study their profession in a liberal spirit, for though the centre of all their work was in man, they must gather up their knowledge from a very wide radius if they were to understand the problems he presented.

#### UNIVERSITY COLLEGE.

*Abstract of Introductory Lecture delivered October 1st.*

By F. T. ROBERTS, M.D., M.R.C.P., &c.

AFTER a few prefatory remarks, the lecturer drew attention to the remarkable progress which had taken place in the medical profession as a science and an art. Instead of considering this subject at any length, however, he thought it would be of more service to those for whom his remarks were intended if he were to discuss certain questions bearing upon the position of the profession, its internal organisation and external relations, and upon medical education and examination. Perhaps it did not matter much whether they as students were up in all the latest theories, or were acquainted with the most recent researches; but it made all the difference in the world whether they were turned out at the end of their career at all competent to practise their profession, and whether they had correct notions as to the position of their calling, its relation to great questions with which it was concerned, and their responsibility and duties in connection therewith. His conviction was that it did a great deal of mischief to allow those who intended to enter the profession to be under sentimental notions as to its nature and position. Essentially, and in the abstract, the "doctor's" calling was everything that ever had been, or could be, said in its praise; but at the same time, when realised in daily life, with its many difficulties and annoyances, with its dull and wearying daily routine, it might come to be regarded as not much, if at all, above the common level. What was worse, the conviction might be forced upon them that their calling was not quite so honourable as they were led to believe, while they could not avoid noticing that its external relations were extremely unsatisfactory in many points of view. . . . Things were certainly better than formerly, and their were signs of still greater improvement, but there was a vast deal still yet to be done in the way of reform. The general social status of the medical profession was not nearly what it might be, and even its most illustrious members could only rise to a comparatively inferior position of eminence. . . . In connection with the Army and Navy Medical Departments these were real grievances of a most serious character. During the last year this country had been engaged in a war, emphatically called a "doctor's war," and while honours had been deservedly showered down upon others, the doctors were left pretty well

out in the cold. The Poor-law Service was in many parts in a decidedly degraded position. Politically, they were simply nowhere, outstripped in the race by almost every other class of individuals, headed by the publican and so-called "working man." Their interests as a profession were not considered as deserving of much notice; even in such questions as those concerning sanitary matters, the opinions of men, who, from their official position, were expected to advise on these subjects, had been quietly ignored, or sometimes insolently repudiated.

The lecturer then went on to remark that it would do no harm if a considerable addition of the medical element were infused into the constitution of both Houses of Parliament, and pointed out the influence the medical profession ought to have in connection with all questions bearing upon the general health and well-being. In considering the causes to which the unsatisfactory state of the profession might be attributed, Dr. Roberts observed that first they were not a numerous or powerful body, and therefore Government cared little about them; secondly, the public did not treat them fairly or kindly—they would take every advantage of them; numbers of persons obtained advice at the hospitals who could well afford to pay, while, on the other hand, they would readily give large sums to some pretentious quack. With all the late increase in charitable contributions towards the hospitals, and the generosity of anonymous donors, who sadly, however, needed direction as to what hospitals should be the objects of their generosity, there was no corresponding development of charity and consideration towards the medical staffs of these institutions. He did not mean that they were not paid—a matter, however, not unworthy of notice—but they were not by any means always properly treated in other respects. People held very wrong ideas about their position, which were even encouraged by some gentlemen in their own profession. The lecturer then spoke about the difficulties and trials which physicians and surgeons to public institutions had to undergo, and in connection therewith alluded to the sad events of the past year, paying a tribute of respect to the memory of Murray, Phillips, Dickson, Fuller, Allen, Webb, Harries, Anstie, and others. Dr. Roberts then drew attention, thirdly, to the obstacles to true progress which existed within the profession itself. He urged the great importance of cordial co-operation and firm union in all their associations, from the most extensive to the most limited, as well as of individual effort, and of the highest exertion possible on the part of every member of the medical profession as to the nature and aims of their vocation.

Turning to consider medical education and examination, Dr. Roberts compared the past with the present state of things, and in speaking of former lecturers, paid a tribute to the memory of the late Professor Grant, and also spoke in feeling terms of Dr. Sharpey, who had recently resigned the Chair of Physiology. Discussing the present aspect of affairs, he alluded in strong terms to the very inefficient examinations still existing, and urged the necessity for a satisfactory curriculum of study, and satisfactory examinations for every part of the kingdom.

He then pointed out the changes and advances which had been recently made with regard to these matters, treating them under the heads of alterations affecting times subjects, and the methods of examination and instruction. Referring to examinations, he entered into a consideration of the causes of the numerous rejections of candidates, and dwelt at some length upon the question as to how far examiners, teachers, and students themselves were respectively responsible for the present unsatisfactory condition of things, as well as their proper relations to each other, and finally pleaded for their combination for the one great purpose of making the profession in reality the high and noble calling which it was in essence. For this end there were wanted examiners fully competent for the duties, and determined to perform them conscientiously and impartially, but yet with due courtesy and kindness—teachers not only possessing the ability, but eager to devote their best energies to the training of those committed to their charge, and students fully alive to their obligations and responsibilities.

After some words of exhortation, direction, and encouragement to the students present, Dr. Roberts concluded his address as follows:—

With all my heart, gentlemen, do I wish every one of you success in the truest sense of the word. But in order to win success you ought to deserve it. We sometimes see a man who has spent his time in idleness and frivolity, in after life, aided by favouring circumstances, get ahead of those who have been diligent and hard-working, and I confess that to

me the sight is not an agreeable one. My sincere desire and hope is that those who have earned success here may achieve it hereafter, though there is no reason whatever why you should not every one deserve it, and remember that a successful life need not be a brilliant or a long one. There are many obscure village practitioners who in reality are far more successful than some who seem to float on the highest wave of worldly prosperity; and there are tablets in this College, erected to the memory of those, who, having scarcely emerged from their student life, accomplished more in their brief career, and were more truly successful than most men who reach their three-score years and ten. To such men would I point you as examples. Follow in their footsteps, make your mark for good in the sphere in which your lot is cast, whether it be large or small. Let your life be not a dark blot or a hideous caricature, but a finished picture, grand and beautiful and attractive to look upon, which will be the admiration of future ages. You may even now, if you choose, be sketching the outline of that picture; and hereafter, if your lives are spared, you can fill it in and make it perfect and complete by devoting yourselves earnestly and faithfully to your duties, whatever they may be, and by taking your part in the conflict with disease and death, in the alleviation of pain, distress, and misery, and in the endeavour to sweep away many of the direst ills which now afflict humanity.

#### KING'S COLLEGE.

*Abstract of Introductory Lecture delivered October 1st.*

By DAVID FERRIER, M.D., Edin.

THE lecturer, after welcoming the students, old and new, remarked that the study of medicine was one which presented peculiar attractions, dealing as it does with subjects of universal curiosity and interest, besides being of a continually progressive nature, and offering practically unlimited fields for new and original research. The important position and great influence which the medical profession at present possessed entailed all the graver responsibilities on those who would worthily fit themselves for their professional duties. In the short time allotted to medical study almost the whole circle of the sciences had to be gone through. The impossibility of doing all well had led to serious doubts on the part of those whose opinion on medical education was of the greatest weight, whether some of the subjects at present included in the medical curriculum should not be cut out, so as to allow of greater concentration on the more purely practical subjects. Thus botany and natural history, which can hardly be considered necessary to enable a man to recognise and treat disease, were proposed to be excluded. The lecturer admitted that, so far as purely practical work was concerned, these, as well as some other subjects which had to be studied, were not absolutely essential, but he thought there was danger in fostering the natural narrowing tendency of all purely professional pursuits, to the exclusion of that breadth of scientific culture which had always been the boast of the medical profession, and to which, as much as to its mere handicraft skill, it owed its recent progress and present position. The disproportion between the proficiency achieved and the time spent in studying these accessory sciences he thought was much exaggerated, and pointed out various relations in which even only a general acquaintance with these subjects was of the utmost practical importance. While some branches of medical study might, without disparagement to them, be admitted to be only of secondary importance, there were others which claimed especial attention as constituting the very foundation of all rational appreciation and treatment of disease. Prominent among these stood physiology, the claims of which he desired to urge, not so much in reference to its position as the key to all scientific knowledge of the nature of disease, which all admitted, but to the less generally recognised important bearing it had on therapeutics or the treatment of disease. The tendency of modern medicine was to place therapeutics on a rational and scientific basis, in contradistinction to its present position, that of almost pure empiricism.

Notwithstanding the thousands of years during which medicine had been cultivated, and the numerous scientific discoveries which helped to constitute the body of medical science, the term "science" was scarcely applicable to that department of it which related to the treatment of disease by means of remedies. Nor would it be till we had succeeded in establishing more definite and precise

efficacy and mode of action of drugs. There was hope that, by the study of experimental pathology and experimental pharmacology, which were only branches of physiological investigation, we might realise a science of therapeutics. The method here indicated as that which rational medicine ought to pursue, was, however, opposed by many who regarded as misleading all attempts to rationalise therapeutics by reasonings founded on physiological experimentation on the lower animals, and who looked upon pure clinical research as the only road to trustworthy results. In support of this position many arguments were advanced; amongst others the mischievous and pernicious errors which the history of medicine showed to have been the consequence of neglecting clinical observation to indulge in theoretical speculation and physiological theories regarding disease and its treatment.

The lecturer proceeded to discuss how far a parallel could be drawn between the early efforts of medical philosophers and the methods inculcated by the physiological physicians of the present day. He gave a short sketch of the development of therapeutics and of the history of the chief revolutions of medical science, and showed that these truly demonstrated the pernicious consequences of medical practice directed by pathological and physiological theories founded on abstract speculation and not on "the contemplation of nature;" and that though, through many errors, some valuable facts have been established, of which we reap the benefit, yet they had often been arrived at by a reckless and hazardous system of experimentation on human beings, which had cost many lives, and from which multitudes had only escaped with debilitated and impaired constitutions. There was, however, little or no analogy between the physiology and pathology of the past and that of the present day, which was founded on rigid experiment conducted according to exact and precise method, and which discouraged all attempts to solve difficulties by mere abstract speculation. To physiological investigation of this character we owe most of our recent progress in accurate knowledge of the intimate nature of diseased conditions. But with all this advance in scientific knowledge of disease and its diagnosis, we are, as far as regards treatment, little better than empirics, unable to give any other reason for our practice than that it has been found beneficial by those who have preceded us. And yet we observe how eagerly everyone, even the most rigid empiric, advances some theory as to the physiological action of the drug he prescribes, and seeks to support his treatment on some rational physiological or pathological foundation. The backward state of therapeutics naturally points to some peculiar difficulties inherent in the subject, or to some imperfection in the method of its cultivation. That the study of therapeutics presents difficulties not encountered in the exact sciences is a fact, the truth of which is easily demonstrated, but which is too often forgotten in the satires levelled at the uncertainty of medicine. The problems to be solved, incapable of being stated with all their data, cannot be referred to exact calculation. Man in a state of health, and much more so in a state of disease, presents such a complex assemblage of phenomena that the discovery of causes by mere clinical observation cannot be but slow and always uncertain. The uncomplicated natural history of disease is difficult to ascertain. Diseases vary and have special features imparted to them by the individuality of the patient; the mental emotions play an important part in the causation, progress, and cure of the disease, so that to allow for each and all of these, as well as many others, to estimate the exact proportion which each has had in the production of the phenomena observed during the progress of treatment, to discount deficiencies and imperfections on the part of the observer, to eliminate all collateral circumstances of personal or other interest in the results recorded, constitute a mass of difficulty which the experience of countless generations has not yet been able to resolve. For if we are to believe the recorded results of therapeutic research conducted under such conditions, we shall be obliged to admit that the same diseases have been equally well cured by the most sanguinary and heroic, and by the most mild and expectant treatment; by remedies founded on the rational pathology of the disease, by infinitesimal parts of nothing, and by peppermint-water. With such conflicting evidence as to the value of therapeutics, need we wonder that "doctors differ" has become a by-word, and that many thinking men, despairing of certainty, have rushed into inveterate scepticism as to the value of medicine in general, and have assumed the position of benevolent neutrality, declining to interfere between the patient and the *vis medicatrix naturæ*.

It is in the nature of the subject, pursued as it has been, that such things should exist; but that we should rest and be thankful, and accept as ultimate facts conditions which may be capable of being overcome, is hardly in consistence with the general spirit of scientific inquiry. We must recognise the necessity of reducing the problem to more limited dimensions, and of bringing the conditions of the investigation under our control, by applying to therapeutics the same exact system of experimentation which has done so much to advance the sciences of physiology and pathology. To experiment on human beings, after the manner of old, is contrary to the genius of the profession; and the progress of research pointed to experimentation on the lower animals as the only means of arriving at that knowledge of the exact action of drugs, which was necessary before a rational treatment could be linked on to a rational pathology. Against this method there were numerous objections, some of which were worthy of serious consideration. It is urged, with some show of reason, that we are not justified in transferring to human beings the results of pharmacological investigation on the lower animals, on account of the differences observed to exist: many drugs which had a powerful action on man exerting little or no influence on animals, and *vice versa*. These facts were acknowledged, several individual instances were discussed, but these anomalies were not to be regarded as ultimate facts any more than the so-called idiosyncrasies observable among patients. Physiological research had already succeeded in explaining several of these peculiarities, and though all difficulties had not been cleared up, the progress they had made justified the hope that they would all ultimately be removed. In the cases where animals and men were affected in all outward respects in a similar manner—and these only were argued from—unless physiology were a fallacy, and biology a myth, the establishment of the action of the drug on one of the lower animals was applicable to man.

Hasty generalisation was greatly to be deprecated; and clinical observation, instead of being neglected by scientific therapeutists, required to be, if possible, more thorough, more accurate, and more minute. The differences occasionally arising between "practical men" and experimentalists showed the necessity that existed for a more thorough union of the physiologist with the physician. The results of trustworthy experience were by no means to be disregarded by the pharmacologist. Often the most successful practice was united with the most erroneous theory as to the action of medicine; but though the theory was proved on investigation to be false, it by no means followed that the treatment should be abandoned. It was more philosophical to endeavour to ascertain the real foundation of its proved usefulness.

It was sometimes assumed that pharmacological investigation had added but little to our *materia medica* as compared with the numerous valuable remedies which had been discovered and established by the method of empiricism, which the rational physician would so much decry. No doubt many of our most highly prized drugs were the result of lucky accident, but many more were the result of hazardous experiments on patients. We could not always wait for lucky accidents, nor were we justified in experimenting on those who sought our aid. Yet it could not be said that therapeutists had reached perfection—witness such opprobria of medicine as cholera, zymotic disease, hydrophobia, &c., before which we had to confess ourselves almost powerless. Physiological research had established many valuable remedies—witness the anæsthetics, hydrate of chloral, nitrate of amyl, calabar bean, and many others—besides extending the use of many already known; while the ascertained facts of physiological antagonism had enabled us to counteract successfully many formerly invariably fatal poisons. Results such as these justified the hope that physiological research would one day clear away the many opprobria of practical medicine. Yet there had been some danger that the progress of scientific medicine should be discouraged by the outcry of a certain class against what they called the inhumanity and cruelty of physiological investigators. The lecturer had no intention of making an *apologia vivisectionis*, for he despaired of convincing its opponents of its morality, seeing it only rested on a principle which was acted on, and necessarily, in almost every relation of life. But he strongly objected to the conduct of those who, professing to have such delicate sensibilities, pryed into what was not written for them, merely for the purpose of misrepresentation and vilifying in the public prints those who might be actuated by as high principles of humanity as themselves. To another numerous class a proverb was applicable, which

defined certain persons as unfit to see things half done—viz., those who could appreciate the benefits arising from certain physiological experiments, but were unable to understand the bearing or practical benefits to be derived from others of a similar nature, and would therefore oppose them as wrong and unnecessary. To such vexatious opposition it was to be hoped there would soon be an end, but apparently with little chance of immediate realisation in such a curious age of general enlightenment and holy pilgrimages. The lecturer concluded with the hope that he might have excited some degree of enthusiasm for the cultivation of rational medicine.

### MIDDLESEX HOSPITAL.

*Abstract of Introductory Lecture delivered October 1st.*

By MR. ANDREW CLARK, F.R.C.S.

HAVING referred to the 1st of October as a day for which medical men had a special regard, the lecturer spoke of the army and navy, and hoped the Government would not permit an idea to gain ground that these services were not sufficiently good openings for young surgeons; of this there appeared to be at present some danger. The importance of preventive medicine was spoken of, and all were urged to study it, even though they did not make public health their speciality; and in speaking of scientific study as a branch of the medical profession, the lecturer pointed out that though our knowledge of pathology and means of diagnosis had of late years much improved, still we were very backward in therapeutics. In acquiring scientific knowledge they must not forget, in the exercise of their duties, charity and true love for their fellow-men. Special stress was laid on this word charity, because the lecturer thought there was a want of charitable feeling existing among medical men themselves, and it was a word all should consider well in its many and varied meanings.

He went on to say that they had two great aims before them: to obtain a legal qualification, and to acquire such a knowledge of their profession as would give them a self-consciousness that they were able to combat any emergency. The two ought to go together, and he hoped that when the conjoint scheme came into operation, the possession of a diploma would be a guarantee of thorough efficiency. He then went through the various subjects of study, and in speaking of anatomy said the only place to learn it was in the dissecting-room, where three or four hours a day should be spent. He thought a student could acquire a sufficient knowledge of physiology without resorting to vivisection, which should only be practised for the purpose of making discoveries, and not for demonstrating known facts.

The lecturer said hospital work should be begun at once, and advised the students to make up their minds to devote a short portion of every day to it, although, at the same time, if any could afford a year before registering for preliminary scientific studies, so much the better.

They were urged to help one another in their work, and not to be afraid to explain to a fellow-student what he was ignorant of for fear of losing a prize. This was one of the objections to class prize-giving, and a very reasonable one; but if they acted on the word "charity," and recollected there was one prize—the acquirement of knowledge—open to all, it would not occur.

Mr. Clark pointed out that no man could be a good specialist without a fair knowledge of disease generally; and every general practitioner should make himself so far acquainted with special diseases that he would not mistake glaucoma for simple conjunctivitis, or pronounce a case of throat-deafness incurable.

The students were advised to hold as many hospital appointments as they were able to obtain, and to begin at once if they had seen any practice, or in six months if they had not, as out-patient dressers; and in fulfilling the duties of those offices they were to recollect that they had the good of their patients as well as their own good to consider. Hospitals were built for patients, and students were permitted to make use of those patients for their instruction for the benefit of others; but they must be treated with every kindness and consideration, and on no account subjected to unnecessary examination if it either prolonged their illness or endangered their life.

In speaking of the subject of cramming for examinations, the lecturer said he feared it was very much in vogue at the present day, and even necessary for some examinations. It was not, however, necessary for the ordinary medical

examinations, and those whose knowledge was acquired by its aid could not be efficient practitioners. Frequent examinations were of great service, and opportunities were offered in the class examinations held every six weeks, at which the students should not fail to be present.

Mr. Clark spoke of the loss the profession and hospital had sustained in the death of Dr. John Murray, whose bust had just been placed in the Museum, as a testimony of the respect in which he was held by his friends. A scholarship had also been founded in the University of Aberdeen, which, under certain conditions, was open to students of the Middlesex Hospital.

In concluding, the lecturer said we should be encouraged to persevere when we think of the many great men who have adorned our profession, mentioning particularly Sir Charles Bell, who had been surgeon to the Middlesex Hospital for seventy-two years; and we know we have the same opportunity as they had.

### ST. GEORGE'S HOSPITAL.

*Abstract of Introductory Lecture delivered October 1st.*

By DR. W. HOWSHIP DICKINSON, Physician to the Hospital.

THE lecturer opened with an allusion to St. George, contrasting his ancient calling as a soldier with his present position as patron to a hospital, wherein he wages no war but with disease, his enemy that crowned shadow whom mortals fear, the frontier in dispute that of the dark monarchy from whence no ambassador returns.

Pausing for an instant on the importance of medicine in reference to the amount of preventable disease, the unnecessary deaths in England alone being equal in one generation to the population of London, or in one week to as many as were put to death in France during the Reign of Terror, the lecturer said—"Sanitas sanitalum, omnia sanitas" may well be accepted, in default of a better, as the motto of a political party; and I think it will be well for the State, and but duly regardful of a waste of life which is only to be paralleled, and that but for a short time, by war on the largest scale and in its most sanguineous shape, when the profession to which we belong is represented in the councils of the nation as weightily as can be insured by official place and conferred dignity.

Proceeding to the present state of medicine in relation to the allied sciences, the antiquity of medicine was contrasted with the modern origin of the sciences with which its advance is connected—old tradition and new knowledge, each with their claims to consideration: medicine, in one view, rich with the spoils of time; in the other, encumbered with some of its dust.

Ancient and mediæval medicine were touched upon, and the mediæval physician sketched as a visionary, with the astronomical globe ready to his hand, and his portrait bordered with the signs of the zodiac, some of whose theories—the doctrine of signatures and the humoral pathology—still influence practice, the latter especially in the absurdities of counter-irritation, some of which were described as more worthy of the genius of Red Indians than of the benevolent intent of one Christian to another.

Turning now to later modes of thought, the great advances of chemistry during the last hundred years were referred to, with the medical improvements consequent thereupon, culminating in anæsthesia by inhalation. Pathology was similarly dealt with, together with the recent origin of the achromatic microscope, and the new views thence derived as to the nature of disease; pathology, like the age, becoming materialist; functional or unsubstantial diseases flitting before the microscope like ghosts at sunrise. The lowest forms of organic life were referred to in regard to the large influence, strangely disproportioned to their minuteness, which they exert as causes of disease upon the fortunes of humanity.

Declining to enter upon the subject of spontaneous generation, but professing himself willing, if necessary, to adopt the view of the Roman Commander with regard to the animals of the Nile—"Your serpent of Egypt is bred now of your mud by the operation of your sun, so is your crocodile,"—the subject of modern advance was completed by mention of the instruments dealing with light and sound which have advanced the art of diagnosis.

Thus, tracing the recent progress in medicine, directly or indirectly, to knowledge extraneous to itself,—seeing for how long in the absence of the sciences it remained stagnant, or

with only fitful progress; how fanciful theories led to erroneous practice which observation alone was inadequate to correct; and how sharing in the development of science it has made greater progress during the last hundred years than since the epoch of Galen, the physician of the early Roman Empire,—to natural science was awarded the first place among the agents of medical progress. But it was not to be forgotten that science, however advancing, was necessarily imperfect; it might mislead as well as lead aright, and prove on occasion, not a guiding star, but an *ignis fatuus*. Hence suggestions thence derived must be scrutinised in their application with suspicious care, ever adjusting, correcting, and, where necessary, renouncing the indications of principle according to the teaching of observed results.

Giving due place to scientific or speculative thought on the one hand, and to experience on the other, the first was the motive power, the second the controlling agent; the first the steed, the second the bridle. With only the one we should be sure to go astray; with only the other we should for ever stand still, or at best advance in a very halting and footsore style.

Theory was insisted on as an idea of purpose inseparable from human action; and practical men, who affect to be superior to theory, stigmatised as no less theoretical than their neighbours, though influenced not by the principles of ripening knowledge, but by the exploded fallacies of the past. "A practical man," according to the great leader, whom, as a conservative, practical men should respect, "is a man who practises the errors of his predecessors."

No therapeutical suggestions should be discarded as too chemical; no pathological inquiry, however minute, as unpractical; no appliances in aid of diagnosis as new-fangled or superfine: observation should be trusted, tradition distrusted.

Students were urged to study the nature and course of disease, so as to be able to interfere with it when necessary and possible, and to be content to leave it alone when, as often happens, the disease of itself tends to health, or, in other instances, is outside the scope of our remedies.

"Let us," said the lecturer in conclusion, "be no mere distributors of salves and potions—for everything its remedy, and half the remedies delusions; but while we practise the art of medicine, study the science of disease, and accept promise of unbroken progress and increasing utility in association with that knowledge of universal nature, ever widening and deepening in all her modes and results, which is the glory of the age and the hope of the future."

#### ST. THOMAS'S HOSPITAL.

*Abstract of Introductory Address delivered October 1st.*

By W. MACCORMAC, F.R.C.S.I., F.R.C.S.E., &c.

AFTER some preliminary remarks, Mr. MacCormac dwelt on the fact that the student must not depend exclusively for instruction on others, but must also, and most patiently, learn to instruct himself. To do this efficiently he should have received a well-grounded preliminary culture. The lecturer pointed out that without such previous training a man is liable to be distanced in the race of life, that the student who finds himself required to fill up the deficiencies of a defective education, as well as to master the intricate details and manifold bearings of a great profession, will prove too heavily weighted either to do justice to himself or the calling he has chosen. Mr. MacCormac combats the idea that in respect of the task before him the termination of the student's career will see the end of his exertions. He shows that excellence is not thus to be compassed, but must be aimed at, struggled for, without end. He points out that effort itself confers a sure reward, a disciplined intelligence, and a well-directed will. He adverts to the relations of the teacher with the taught, the genial bearing of the one influencing the apt intelligence of the other—that there is between them a community of purpose which, rightly exercised, will lead to the best results, and that the student has no better friend or confidant than his teacher.

The long career of the ancient foundation of St. Thomas's affords Mr. MacCormac the opportunity of giving some interesting details of the position of surgery and surgeons in bygone days—that there was specialism, and of a very bad form, then as now. He points to some of the extravagances that were then committed, and the absurd length to which the belief in certain remedies was carried; quoting the somewhat amusing instance of a physician who, having refused to be bled in his extremity, was snathematized with

the depletion which it was hoped he might have to undergo in a different world. The lecturer forcibly dwells, however, on the debt of gratitude we owe to the worthies of the past, and to the immense difficulties which they not only encountered but overcame, and urges us

"Ever to be mindful of the Faithful Dead."

Mr. MacCormac is justly appreciative of the enormous contributions made to modern science on the part of Continental practitioners, and dwells upon the necessity of an acquaintance with the languages in which those labours are recorded.

"There are," he says, "workers everywhere; but how are we to benefit by their work unless we understand their language? We may, indeed, avail ourselves of translations, but these at best are but diluted transcripts, bereft of all the life and verve of the original, and mostly come too late to prove of much advantage. We are, in fact, somewhat prone to wrap ourselves up in our insularity, if I may adopt the expression. Insularity may be an admirable thing geographically speaking, but in science it is too often fatal." The long list of names—too long to enumerate—of German, French, American, and English surgeons to whom surgery and the world are indebted is securely registered in the record of their fame.

The great efforts which have been made to mitigate the horrors of modern warfare are spoken of in the pages of Mr. MacCormac's address; and he enlarges on those efforts as one may who has witnessed something of the evils they are intended to assuage. He shows how much our times are in advance of the past, but he also shows how even the immense resources of modern military surgery find themselves unequal to cope with the horrors of such modern battle-fields as those of Mars la Tour and Gravelotte, where 42,000 men fell dead or wounded on the German side alone.

In conclusion, Mr. MacCormac urges the student to cultivate, at once as a solace and recreation, some pursuit not immediately bearing upon his profession. He points out that of many within reach none is perhaps better deserving attention than the cultivation of general literature, which, as Sir John Herschel has said, places its possessor in contact with the best society of every period of history, makes him a denizen of all nations, a contemporary of all ages.

#### CHARING CROSS HOSPITAL.

*Abstract of Introductory Address delivered October 1st.*

By R. DOUGLAS POWELL, M.D., M.R.C.P.

AFTER some preliminary remarks, Dr. Powell observed that it was, perhaps, only on hearing the usual but none the less sincere congratulations upon the nobleness of the profession they had chosen, which were always offered to them upon these occasions, that students first questioned themselves, curiously, as to how they came to choose the medical profession; and the question, What is the use of it? might to them at first appear a little staggering. For, merely to say that the profession existed; that, of its superabundance, civilisation had yielded a fund for the lopping of overgrowths, the repair of degeneration, the preservation of buds and cuttings; and that thus doctors, like cooks and confectioners, were but the results and servants of luxury—was not a sufficiently encouraging answer to urge them onward. Nor, although a contingent pleasure, was the occasional sense of gratification that the immediate object of their lives was the relief of pain and misery, sufficient to justify to them their profession as a great one. It was too fitful and fleeting to sustain them to any high purpose, and was rather an element of over-anxiety and weakness if it held too high a place in the mind of the physician. On looking higher still for a worthier motive, they were met by the protest of some who would thrust them back again amongst the cooks and confectioners—that, by ameliorating the conditions of life, they preserved the feeble members of the human race at the expense of the strong, levelling down the whole human constitution by diluting the life of the strong with the lesser vitality of the feeble. He need not pause there gravely to contend against the futile notion that it would be possible for us to interfere with such laws of nature as determine the survival of the strongest. Such laws could not, however, be construed to mean that life was the exclusive right of those who had

most of it. The laws of Nature, "bound fast in fate," were not to be changed by human will; but it seemed obvious enough that by improving the general conditions of life we acted with those laws, and upheld, if he might so say, rather than let down, the vitality of the race; for every evil condition that would extinguish a weak life, would damage, if not disable, a strong one. Proceeding to regard the matter from another aspect, Dr. Powell contended that in the intellect or mind of man, we found a new force having, within wide limits, the mastery over other forces, and, unlike them, capable of continued growth from generation to generation, and that the true aim of civilisation—a great scheme of Nature in which we but took our part—was towards the attainment of a higher development of the intellectual and moral elements of our being, to the crowing with God-like wisdom and grace that human form which, in muscle, and bone, and nerve, was as perfect centuries ago as now. He doubted whether in this direction any man had ever lived whose life had not contributed directly or reflexly to human advancement, the weak being the hostages of the strong, to bind them to industry, to lessen violence and strife amongst them, and to humanise them. The ascertainment and maintenance, then, of the laws of life and health, mental and physical, under all the conditions of human existence, was a worthy and sufficient *raison d'être* for ours as a profession, being, in other words, the maintenance of the best bodily or material conditions for continued intellectual growth.

Dr. Powell next urged upon his hearers the importance of early establishing for themselves a good tradition to which they would find it comparatively easy to remain loyal. He thought astuteness and decision of mind, the habit of thinking out everything to a conclusion, so attractive and commanding in the man, was particularly valuable in the professional man. He dwelt on the importance of note-taking and personal examination into everything as the best means of gaining early real experience, the safest antidote in practice to that indecision of mind against which he had already spoken. He warned senior students particularly against neglecting any branch of medical study; a man could only legitimately become a specialist after having thoroughly acquainted himself with the principles of medicine and surgery as exemplified in their every branch and department. Most of them would practise in every branch. Mentioning especially the diseases of women and children as being branches of study often somewhat neglected by students, he observed that the reflex phenomena of disease which make up a certain portion of the symptoms of all diseases, were often most clearly and simply presented to us for study in these departments, and that a good knowledge of children's diseases was the very alphabet of medicine, teaching us the resources of nature, and how best to aid them by rest, diet, nursing, and medicine.

Dr. Powell concluded his address as follows: Some noble experiments were being tried in establishing provident dispensaries on true self-supporting business principles, in which charity took no part. It would, however, take time for them to become rooted institutions, and meanwhile he would advise every man commencing practice to make his surgery a provident dispensary, where a payment qualification during health might enable the poor man to seek advice and treatment during sickness. They would thus gain opportunities of continuing the study of their profession and ensuring future reputation, and this in the true interest of their poor patients rather than at the expense of their moral integrity.

#### WESTMINSTER HOSPITAL.

*Abstract of Introductory Address delivered October 1st.*

By R. D. POTTER, M.D., M.R.C.P.

AFTER a few words of welcome to the students, and alluding to the sad loss sustained by the school in the deaths of Dr. Frederic Bird and Dr. Anstie, both cut off in the midst of active work and in the full vigour of professional life, the lecturer went on to speak of the profession of medicine, and to congratulate those who had embraced it on their choice of so noble a life. But he told them that they must be certain of the truth of their choice, as they would find it a hardworking profession, success difficult of attainment, State rewards but few, and the chances of making a fortune infinitesimal. He continued: "To be honoured professionally, however, is open to you all, and it is rare that honest work remains unrewarded

in this way. It is a source of pride to us that of the four seats of the Censors' Board of the College of Physicians two are at present held by the senior members of the staff, Dr. Basham and Dr. Fincham." After reminding his hearers that they are to be medical students, he went on to speak with regret of the abolition of the old-fashioned apprenticeship, believing that a year or so occupied in this way would be of great advantage. The seeing a great deal of practice, and especially the minor and petty cases, which make up, to a large extent, the bulk of every day work; also the minor diseases of children, scarcely ever seen in a general hospital; the handling of drugs and the art of prescribing, never successfully learnt in any other way; the traditions and etiquette of the profession; and last, not least, the opportunity it affords the young man to ascertain whether he likes or dislikes the profession of his choice, as he sees, in addition to the purely medical point of view, the kind of daily life that he must expect if he goes on with it. A good deal of elementary knowledge can also be gained during this year of botany, chemistry, and some acquaintance with the bones. Turning for the moment to address especially the students making their first appearance in the theatre, he insisted strongly on the necessity for order in their medical studies, and especially at first to devote themselves mainly to anatomy and the dissecting-room, afterwards taking up physiology, and especially to work well in the new physiological laboratory, where they would have advantages of experimental research such as were not enjoyed by their predecessors in the school.

Speaking on the subject of midwifery, he dwelt on its importance as the keystone to practice, and laid great stress on the necessity of a sound practical knowledge of the subject, and the attendance on as many cases of labour as possible. He spoke also of the impossibility of attempting to teach the diseases of women and children as part of a three months' course of midwifery. The importance of taking notes in the class-rooms and also in the wards was strongly insisted upon. The advantages of Westminster Hospital, as *par excellence* a small school, were then dwelt upon, "for though a student of robust health, commanding talents, and great industry, might push his way to the front in a large school, it is far otherwise with many others. In a small school, where there is no crowding, everyone has his chance, is brought more closely into contact with his teachers, in the wards he sees all the cases without having to fight for the privilege, and in the latter years of his student life is able to hold the various appointments, and have the direct charge of patients."

## Hospital Reports.

### ON A REMARKABLE CASE OF TRISMUS.

By RAWDON MACNAMARA, M.D. (Hon. Causá) Univ. Dub.,  
Fellow, Member of Council, Professor of Materia Medica, and Ex-President R.C.S.I., Surgeon to the Meath Hospital, &c.

I FEEL that but little apology is due for my thus bringing under the notice of my professional brethren the principal features of the following case, which I look upon as the most remarkable one that hitherto I have met with in the practice of my profession.

E. L., a married woman, æt. 52, was admitted into the Meath Hospital under my care on the 24th day of July in the present year. The symptoms under which she laboured were as follows: Her jaws were firmly locked together, and could not be separated either voluntarily or by any amount of force which I considered justifiable to use, even to the extent of admitting the introduction of a spatula, and this state of rigidity was equally well pronounced both whilst the patient was asleep or awake. In the situation of the right temporo-maxillary articulation was an immovable tumour of the size of a pigeon's egg, giving, on digital examination, a cheesy-like sensation; the sternal attachment of the right sterno-cleido-mastoid muscle was remarkably thickened, fully six times as large as that on the left side, communicating to the finger the same cheesy-like sensation; whilst under the right clavicle were two tumours apparently similar in character to that

over the temporo-maxillary articulation, but much smaller in size, not being larger than a hazel-nut, and under the left clavicle were two others of similar character, but still smaller in size, not being larger than a marrowfat pea. Upon the surface of the chest the cutaneous veins were visibly enlarged. Her pulse was slightly accelerated; but no difference in volume was observable at the wrists on either side. Her voice was remarkably hoarse, and the act of inspiration was accomplished with very great apparent difficulty, and accompanied with a loud crowing noise, resembling in character but far exceeding in intensity that heard in croup or in the very worst forms of whooping-cough, and perhaps the most remarkable feature in this extraordinary case was that the sounder asleep was this poor creature the louder would be the noise accompanying the act of inspiration, so much so as to disturb the patients at night, not only in the ward in which she slept, but also those in the adjoining wards, which noise was also perfectly audible outside the walls of the hospital even with the doors shut. With all this she would sleep profoundly, but never awoke from her sleep refreshed. This noise was so overpowering as entirely to prevent even an approach to anything like a satisfactory stethoscopic examination of her chest, although such was most kindly and most perseveringly essayed for me by my venerated colleague Dr. Stokes, who pronounced the case to be, in his experience, unique. In her general appearance she appeared to be slightly emaciated; but in all other respects save those mentioned she seemed to be in a fair state of health. She had little, if any, cough. The history which we could collect from herself of her case was briefly as follows: About Christmas last she remarked that she was getting hoarse, and fancying that she had caught cold she procured some cough-bottles, which, however, did not do her the slightest good. Shortly afterwards she remarked the tumour seated over the temporo-maxillary articulation, at first small in size, which from that time increased steadily to its present condition. Early in January she experienced difficulty in opening her mouth, and in February the jaws closed tightly, as they are at present, since when she has been obliged to feed herself by coaxing crumbs of bread through an interstice left by the loss of one of her front teeth when a child. There is not the slightest evidence of her ever having suffered from syphilis, all the evidence tending in the contrary direction.

The diagnosis in this case was involved in obscurity. That the temporo-maxillary tumour might have something to say to the production of the trismus could not be gained. Still, I had frequently seen tumours in this situation larger in size, and apparently of a graver character, where, although some difficulty would be experienced in opening the mouth, yet there never was anything approaching the completely lock-jawed condition this poor creature presented. Again, what was the cause of the extremely exaggerated inspiratory murmur, and the diagnosis being so obscure, naturally it was still more difficult to decide upon the line of treatment most likely to relieve the symptoms. After mature consideration the conviction forced itself upon my mind that the "fons et origo mali" lay deep down in the thoracic region—that a tumour similar in character to those to be observed externally had formed internally, and by pressure on the nerves had set up reflex irritation, whence all the symptoms. In a communication such as this, it would be, in my opinion, out of place to enter into a physiological discussion as to the nature and situation of the pathological changes which might result in the production of these phenomena. On a future occasion it may be permitted me to do so; but at present I must content myself with placing on record facts as they occurred. With this conviction upon my mind, I discarded the idea of tracheotomy, which for a time I had entertained, and determined on making energetic efforts to procure the absorption of the tumour, if such there was. With this object in view I placed her on mercurial inunction, until the gums became tender. No difficulty was experienced in producing this result, and then I placed her on large doses of iodide

and of bromide of potassium. After a few weeks of such treatment all the symptoms commenced to ameliorate, the tumours which were visible diminished in size until at last they disappeared. She is now able to open her mouth, to masticate food (clops, steaks, &c.), sleeps tranquilly, and to all outward appearances seems to be perfectly cured. It should be mentioned, as being to some extent supplementary to the proof afforded, by the success attending the treatment, of the probable correctness of the diagnosis; that, when the character of the respiration admitted of a satisfactory examination of the chest, I found in the track of the arch of the aorta, on percussion, dulness; on auscultation, a well-marked murmur, which murmur, however, was not at all detectable over the cardiac region. Both of these signs are so diminishing in intensity as now to be scarcely, if at all, recognisable. In this statement I believe that I shall be fully supported by my friend and relation distinguished Professor Brown, of the Galway College, who kindly examined the case for me this day (October 2nd).

During her treatment she used about six ounces of the bromide and five of the iodide of potassium. The mercury was not employed through the existence of suspicion on my part of any syphilitic complication in the case, but because experience has taught me its value when thus used as a preliminary in developing the absorbi-facient properties of the iodides, and with this object in view I also occasionally had recourse to the local abstraction of blood by half-a-dozen leeches at a time.

During the treatment of this case I had reason to feel indebted to my resident pupils, Mr. R. M. Blake, one of my apprentices, and Mr. Clibborn, for the zeal and attention with which they carried out my directions, and to the former of these gentlemen I am also additionally indebted for the accurate notes from which I have been thus enabled to summarise this most instructive and interesting case.

## The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 7, 1874.

### THE FIRST OF OCTOBER.

THE Introductory Lectures this year were successful. Such is the general verdict of professional society in London; and we may add that some of them were of unusual interest. It is unnecessary to enter on a defence of the custom of inaugurating the session in the time-honoured way, although a medical journal has thought fit to depreciate it by a feeble attempt at cynicism. That journal has, however, published two of the lectures *in extenso*, and given abstracts of the others. If they were so useless, why publish them? Our own views on the

matter have been previously stated, so that it is unnecessary to repeat them.

Guy's was a scene of excitement on the 1st of October. Not only Guy's men, but many others would naturally desire to hear a man who has attained the position occupied by Sir William Gull, and accordingly a larger room had to be sought outside the hospital. Many will have rejoiced to hear Sir William Gull say he looked back with pleasure to the time when he had no world but Guy's; and it must have stimulated his younger hearers to hear him confess that he traced all his success to work in its wards. Nor was his kindly word for *Guy's Hospital Gazette* less likely to be appreciated as a proof of lively interest in all that relates to his *alma mater*.

Considering, too, the general impression as to the sceptical nature of his mind, it would be a relief to many to hear, after the able exposition of the order of nature, of man's subjection thereto, and of the reasons for preparing themselves for the duties of their profession, that the lecturer added this advice: "Supplement these by the highest, your duty to the Highest, Who alone can satisfy the wants of your nature, and with Whom a faithful study of your profession cannot but make you better acquainted."

At King's College Professor Ferrier inculcated the study of rational medicine, and laid much stress on experimental physiology, of which he is so able a cultivator, and he evidently looks for great advances in our knowledge of therapeutics. His subject led him to speak of vivisection, and he spoke decidedly in a manner that would displease its opponents, but he did not assert that it should be permitted except for truly scientific investigation, and so we presume by qualified experimenters.

At University College Dr. Roberts discussed the position of the profession, its organisation and external relations, medical education and examination. In his view, medical politics are evidently important, and we could wish, now that introductory lectures have become of interest to the public, that they were more generally made the media for such remarks.

At St. Thomas's Hospital Mr. MacCormac gave the results of his investigation into the history of surgery during the long time the hospital has existed, and interspersed sketches of former surgeons that are full of interest.

Mr. Andrew Clark alluded to the late Dr. Murray, and other Middlesex Hospital worthies, as examples for those to whom he spoke, in a very able lecture full of sound advice.

Dr. Fenwick's address at the London Hospital we print in full, and it speaks for itself as the sound advice of a clinical teacher who is still an earnest student.

Dr. Dickinson's, at St. George's, resembles this in some points, and the abstract we give of it will be read with interest. So, indeed, will all.

Dr. Powell, at Charing Cross, alluded to specialities, and stated the exact truth when he observed that "a man could only legitimately become a specialist after having thoroughly acquainted himself with the principles of medicine and surgery as exemplified in their every branch and department." He concluded with a remark

on provident dispensaries, which accords with our own views, though it will doubtless excite opposition.

Mr. Owen condemned special hospitals, though he approved special departments in general hospitals.

We have selected these points for mention, but many others might have been just as well taken; indeed, the lectures are full of topics, any one of which would suffice for several articles. We refer our readers, then, to the reports we give, assured they will find much to please them.

## THE INITIATION OF SANITARY LEGISLATION IN IRELAND.

THE anticipation to which we gave expression when, the week before last, we deplored the error which had been committed in entrusting the regulation of salaries and the discharge of the most important sanitary functions of Ireland to boards of guardians, bids fair to be verified more speedily than we had expected. The circular of the Irish Local Government Board called upon the guardians (as the sanitary authority) to proceed at once to elect officers, but, at the same time, recommended that "the allotment of salaries be deferred until the amount of work be ascertained." In proceeding to carry into effect these somewhat inconsistent instructions, the rural sanitary authorities have been divided into two bodies. One section, which proves itself to be the strongest both in number and in energy, protests against and denounces the proposal to appoint a sanitary staff—considers that the health of the country is quite good enough as it is—believes that a few cesspools and dung-heaps, more or less, are not worth speaking about—objects with much vehemence to increasing the taxes—would be glad to let the doctors do as much sanitary work as they liked provided they expected no payment, and finally, resolved to resist sanitation by every constitutional means.

To this body of recalcitrants belong the guardians of Ennistymon, Bandon, Skibbereen, Tobercurry, Ballymoney, Athy, and many others. We are ashamed to say that amongst the opponents of improvements Mr. McCarthy Downing was conspicuous, and that he informed the Skibbereen guardians that he anticipated that there would be a very general opposition to the Local Government Board, for that all Ireland was taking the matter up.

The second section of the rural sanitary authorities are those who, having involved themselves in a hopeless effort to understand the Act of Parliament and their own duties, have been obliged to postpone the matter to another occasion, or else make appointments in the dark. Being ordered to appoint the dispensary medical officers as health officers, they were entirely in the dark as to the amount of salary to be fixed. Many of them did not consider a consulting health-officer necessary at all, and some of them having selected such an officer, found that he refused to act because his salary was not stated. At Abbeyleix the clerk of the union was very properly nominated as executive health officer, but refused to accept the office at the salary of £10, which was proposed, and the guardians were compelled to "try back" and rescind their vote with a view to an increase.

The first effort at Irish sanitation seems thus to have

been very unfortunate, and for the present the working of the Act is an utter and miserable muddle. It would have been wiser, as we think, for the Local Government Board to have made in the first instance some effort to assess the reasonable amount of salaries, basing their calculations upon the extent of the district, the ratio of its population per acre, and the social condition of that population. The number of dispensary tickets issued in the district, and in doubtful cases the knowledge of the locality possessed by the Local Government inspector would, with the other available statistics, have enabled them to offer to the rural sanitary authorities some practicable suggestions upon the subject, and we imagine a great majority of the guardians would have gladly availed themselves of the advice, if only to escape from the dilemma. The whole transaction is a pitiful illustration of the evils which are created by the timidity of legislators and the want of vigour and good sense in the framing of sanitary law. In order to disarm opposition and get the Bill through Parliament in some shape or other, the motive power of the system is placed in the hands of persons whose direct interest, in many instances, it is to resist the carrying of the measure into effect, and who, in any case, are supremely ignorant of the subject, and usually entirely incapable of making themselves acquainted with it. We declaim about the want of cleanliness, the propagation of disease, the extravagance both of health and money involved in the neglect of precautions; we appoint a commission and pay experts to frame a faultless system, and at great expense, and after much talking we solemnly decree that this system shall be the law of the land; and then! we put our complicated machinery into the hands of men who think that the whole affair is a mistake, and who are densely ignorant of its principle, perfectly incapable of working it, and quite unconcerned as to whether it goes smoothly or stops altogether. Is it any wonder that the machine has to be sent back time after time to be cobbled and readjusted by those who were afraid to make it right at first, and meanwhile the *désagréments* which it was intended to remedy increase and flourish, and the public suffers.

In the case of Irish sanitation, the real fact is that Sir M. H. Beach and his Government feared to forfeit the support of twopenny town councils and boards of guardians, and were induced to introduce into the Bill modifications which have made it, though excellent in principle and object, one of the worst and most unstatesmanlike measures which ever emanated from Parliament.

## Notes on Current Topics.

### On Rabies Mephitica.

A WRITER in the *American Journal of Science* believes that he has discovered a new disease, which is related to hydrophobia and that odious animal the skunk. This discovery he names "Rabies Mephitica," and thus relates what first called his attention to the novel facts presented: While on a tour in the Rocky Mountains our camp was invaded by a nocturnal prowler, which proved to be a large coal-black skunk. Anxious to secure his fine silky fur uninjured, I attempted to kill him with small shot, and

failed. He made characteristic retaliation, and, then rushing at me with ferocity, he seized the muzzle of my gun between his teeth! Of course, the penalty was instant death. An experienced hunter then startled us by saying that the bite of this animal is invariably fatal, and that when in perfect apparent health it is always rabid. He resented our incredulity, and confirmed his statement by several instances of dogs and men dying in convulsions shortly after being thus bitten. On mentioning this adventure to H. R. Payne, M.D., who had been camping with miners near Canon City, Col., he said that at night skunks would come into their tent, making a peculiar crying noise, and threatening to attack them. His companions, from Texas and elsewhere, had accounts to give of fatal results following the bite of this animal. Since returning to Kansas city I have had extensive correspondence with hunters, taxidermists, surgeons, and others, by which means the particulars have been obtained of forty-one cases of *Rabies mephitica* occurring in Virginia, Michigan, Illinois, Kansas, Missouri, Colorado, and Texas. All were fatal except one; that was the case of a farmer, named Fletcher, living near Gainesville, Texas, who was twice bitten by *M. macroura*, yet recovered, and is living still. On further inquiry it was found that he was aware of his danger, and used prompt preventive treatment. Another case was alleged to be an exception, that of a dog which was severely bitten in a long fight with a skunk but whose wounds healed rapidly and without subsequent disease. It seems, however, that this dog afterwards died with mysterious symptoms like those of hydrophobia in some of its less aggravated forms.

The writer proceeds to give the particulars of a large number of well-authenticated cases of this new disease, and the peculiar manner in which its victims were affected. He continues: It is evidently the opinion of Dr. Janeway that the malady produced by mephitic virus is simply hydrophobia. Should he be correct, then, all that is established by these facts would be this—viz., that henceforth the varieties of *mephitis* must be classed with those animals that spontaneously generate poison in the glands of the mouth and communicate it by salivary inoculation. From this, as a starting point, we might go further, and seek a solution of the whole mystery of hydrophobia, in the theory that this dread malady primarily originates with the allied genera of *Mephitis putorius* and *Mustela*, widely scattered over the earth, being from them transferred to the *Felidæ* and *Canidæ* and other families of animals.

### An American Debate on Cancer.

THE London debate on cancer will be fresh in the minds of all our readers. As appendant to it we give the following account of a debate at the Baltimore Medical Society, reported in the *Philadelphia Medical and Surgical Journal*.

Dr. Monmonier exhibited a scirrhus tumour removed from the breast of a lady patient of Dr. Arnold. The wound was healing nicely.

Dr. Friedenwald asked how much the patient was benefited by the operation.

Dr. Monmonier said that the benefit is that the removal of the tumour relieves the pain and gives the patient a

chance. Of course, it is impossible to tell whether it will return or not.

Dr. Friedenwald was of the opinion that every case operated on had been a failure; the benefit is very temporary, and in a few months the disease generally returns; he looks upon all cancerous affections as extremely unfavourable. A lady suffering with a tumour in the breast called in Dr. N. R. Smith, who advised ablation. Some of her friends advised her to try electricity, which she did without receiving any relief. Then she was recommended to apply to a cancer doctor from the Eastern Shore, but not having sufficient money to meet his demands she was induced to enter the Hebrew Hospital. Dr. A. P. Smith removed the breast. Upon cutting down upon it a serous liquid escaped, and the tumour collapsed; he carefully dissected out the cyst, closed the wound, and the patient got well; but in two months after the disease had returned in the form of melanotic cancer, from which she died in three or four months.

Dr. Lynch remarked that all true cancers are constitutional, but scirrhus is in many instances only a local affection. In 1862 he was called to see a slave, æt. fifty, who had a large tumour in the breast, hard as a stone, producing a great deal of pain. On July 4th, 1862, it was removed, together with every gland which appeared to be involved in the disease; four ligatures were applied and the wound closed. The incisions healed by the first intention except a small portion at the inferior angle. Up to 1872 there had been no return of the disease. The tumour was so hard that to make an examination of it a hatchet had to be used to cut it open.

Dr. Monmonier said he had operated on some five cases, in one of which the glands were very much enlarged, but in none had there been a return of the disease. English surgeons say that scirrhus is a local affection, and not a constitutional disease.

Dr. Morris said he had a case of cancer of the breast now under treatment, in which there is no pain in the tumour, but excruciating pain in the sciatic nerve. Drs. Johnson and Miltenberger have seen the case, but can offer no relief. Large doses of morphia combined with chloral have to be given at short intervals.

Dr. Lynch asked whether the pelvis had been examined to see if there was a tumour pressing on the sciatic. He could not see the connection of the two unless there is cancerous disease of the pelvic glands.

Dr. Morris said the pelvis had been examined superficially, not *per vaginam*.

Dr. Bates referred to a case of scirrhus occurring in a relative. Dr. Valentine Mott removed the breast more than ten years ago, and up to the present time there had been no further trouble. He thought removal was justifiable in these cases, even though we believe the disease will return, because by the operation the patient is relieved, for a longer or shorter time, of the intense pain; and then there may be the possibility of permanent cure. Diseases are affected very little by what we believe, and where death is otherwise inevitable we are not justified in depriving our patients of every chance of life. It is the opinion of surgeons that if the lymphatic glands are not involved there is a reasonable ground for expecting a cure,

but if they be much implicated the disease will most likely return. Within a few years there seems to have been a complete change in the treatment of the wound made by the operation. Formerly it was insisted on that union by first intention was to be desired. Now some, surgeons teach that suppuration should be encouraged in order that all particles of cancerous matter may be removed.

Dr. Monmonier said that the English surgeons are in favour of a certain amount of suppuration. Dr. Erich had treated a patient in which the disease was both local and constitutional. The woman suffered from scirrhus of the uterus. Symptoms indicative of acute gastritis supervened, and the patient died. On post-mortem examination a large scirrhus tumour was found occupying the walls of the stomach, and four or five small deposits in the bowels.

Dr. Morris said that Dr. Lynch could not see why scirrhus of the breast should produce the severe pain in the sciatic nerve. As a case showing how irritation of an organ may produce pain in a very distant part, he would refer to the case of a prominent physician of this city. He suffered with neuralgia of the fifth pair for more than a year, used various remedies, and had his teeth removed, but obtained no relief. Thinking that probably a change of climate would benefit him, he went to Jamaica, but returned much reduced, and worse than ever. He also suffered from prostatic disease, could never empty his bladder perfectly, and had frequently voided pus. By the advice of some of his professional friends he resorted to the use of the catheter and has not been troubled with the neuralgia since.

#### Tracheotomy on a Child Sixteen Months old, for Croup—Recovery, and Ejection by the Mouth of a Fibrinous Clot in a Month afterwards.

DR. HEMLEY relates a case of this kind, where the child presented the most marked symptoms, with almost complete absence of respiration in the left lung. Tracheotomy was performed, when in a short time the respiration fell remarkably, and the child was able to suckle. It made a rapid recovery, and in one month afterwards, being seized with a sudden spasmodic cough, it ejected a clot about the size of a boiled pea, which on section and microscopic examination showed its composition to be fibrinous.

#### The London Societies.

MOST of the Societies will have held their initiatory meeting before the appearance of our next number. The Obstetrical meets on the 7th inst.; the Clinical on the 9th; the Medico-Chirurgical on the 13th.; the Harveian on the 15th.; the Medical on the 9th inst.; and the Pathological on the 20th inst. The times, places of meeting, and the general arrangements are the same as heretofore.

It is hoped that the number of deaths from the fearful explosion in London last week will not exceed the three men who were on board the barge at the time. Of course, the destruction of property is very great, no less than a thousand houses being more or less damaged.

### Action of Ergot on the Infant.

THE opinion that ergot does not cause the death of the child during labour is somewhat strengthened by a case related by Dr. E. R. Herschel in the *New York Medical Record*, in which a new-born infant, by accident, received half a teaspoonful (thirty drops) of Squibb's fluid extract of ergot. Efforts to make the infant vomit failed. In an hour it was seized with severe abdominal pains, recurring every fifteen minutes, and lasting about one minute. Slight tetanic contractions of the face and extremities were present, and four hours subsequently diarrhoea set in. All the symptoms yielded to hot baths in twelve hours, though for two weeks there was a tendency to diarrhoea.

### Suffocation of a Child.

AN inquest was recently held at the Marylebone Workhouse, by Dr. Hardwicke, on the body of J. S. Lopez, aged 2 months, the infant son of Mr. Lopez, of 15 George Street, Portman Square.

Annie Clark, nursery governess in the family, stated that she accompanied the wet nurse with deceased and three other children for a walk; the face of deceased was covered with a handkerchief. Upon their arrival home she went into the parlour, and the nurse took the deceased up-stairs, but she returned almost immediately, and put the child in her lap, when she discovered it was dead.

Mr. Lopez said that his wife was unable to suckle the child, and he engaged a wet nurse. On the day of the occurrence he heard a scream, and going into the parlour he found his child dead in the arms of Miss Clark. He immediately sent for Dr. Roberts, who attended.

Dr. Roberts stated that he had made a post-mortem examination of the body, and found a quantity of milk in the windpipe, which had caused suffocation.

The wet nurse (a very young woman) stated that when she took the infant up-stairs and removed the handkerchief from its face she thought it looked very strange, and ran down-stairs and placed it in Miss Clark's lap.

The coroner said the death probably arose from the inexperience of the nurse, and he hoped it would be a caution to her for the future. The jury returned a verdict of "Accidental death."

### University of Edinburgh.

DR. RUTHERFORD, Professor of Physiology in King's College, London, has been elected to succeed Professor Hughes Bennett in the Chair of Physiology in the University of Edinburgh. It is probable that Prof. Ferrier will take his class at King's College.

### The German Sanitary Congress.

THE meeting of this association was held at Dantzic on Sept. 12th and three subsequent days.

The first subject discussed was "The Demands of Public Hygiene on the Regulation of the Buildings of New Parts of Towns, Streets, and Houses."

The second question was "The Influence of different Dwellings on the Health of the Inmates, so far as could be ascertained by Statistics." From observations made in Berlin, it appeared that cellars and attics were both particularly unhealthy, and liable to produce diarrhoea.

On the second day an examination of the drainage and sewerage of Berlin was made, under the guidance of Herr von Winter.

The next subject discussed, on the third day, was "The Reasons for and against the Congregation of different Kinds of Disease in a Hospital."

Dr. Birt, of Berlin, brought forward some interesting facts in connection with the subject of "The Employment of Women in Factories;" after which Professor Reichardt, of Jena, and Engineer Schmich, of Dresden, urged the necessity of an ample supply of spring-water to towns, whatever difficulties had to be overcome in order to render the quantity sufficient.

### The "Worcester" Training Ship.

A SEVERE outbreak of scarlet fever has occurred amongst the boys on board this ship. The authorities of the vessel, however, having acted promptly on the advice of the sanitary officers, the epidemic has been checked, and effective measures taken to prevent its spreading.

### Hunterian Society.

A MEETING of this Society will take place at the London Institution on October 14th, at 8 p.m., when Dr. Richardson, F.R.S., will read a paper on "The Pathological Results of Pectous Change in Colloidal Structures."

### Scarlatina in Dublin.

THE last report of the Registrar-General records a remarkable diminution in the large number of deaths from scarlatina which we noted as having occurred in the previous week. The mortality from that disease for the week which terminated on the 26th of September was only 18, or 16 less than in the previous week. We can hardly hope that so great a diminution can be permanent; but it leads us to believe that the epidemic is rapidly declining, and that the danger of the further extension of the disease will have ceased before the return to town of the families who have been spending their summer at the suburban watering-places.

### Pointed Coccyx.

AT a meeting of the New York Pathological Society, in April, Prof. L. A. Sayre exhibited the lower end of a coccyx from a young lady, having been congenitally malformed. The end was very sharp, "as sharp as a needle," the doctor said, and bent outward and backward. The sensation of pain, says the *Philadelphia Reporter*, was so exquisite that she could not sit upright, but always bent over. As a result, her form became bent, and chorea supervened. She finally came under the care of Dr. Sayre for the treatment of "Pott's disease." The extremity shown was excised. After the bone was sawed off the action of the muscles caused a very large opening to appear, much larger than the space occupied by the bone. It filled up nicely, and the hysterical symptoms disappeared.

WE understand that the *Graphic* of Saturday next will contain a biographical notice of the late Dr. Arthur Jacob, together with a portrait engraving taken from the painting in the Royal College of Surgeons in Ireland.

### Incompatibility of Pharmacy and Medicine.

THE *Pharmaceutical Journal* says that the Court of Appeal at Brussels has recently confirmed a judgment which condemned Dr. Camphenout for having supplied his patients during three years with homœopathic medicines. The decision of the Court was based upon a law of 1818, by which a medical man is absolutely interdicted from practising pharmacy together with medicine, except in certain specified cases, even although he may hold the diploma of Doctor of Pharmacy. A medical man is not allowed to supply medicines to a patient even gratuitously.

### The Chair of Chemistry in Dublin University.

WE understand that it is in contemplation to divide the Professoriate of Chemistry, which has been long held with much distinction by Dr. Apjohn, into two separate parts, the medical section of the subject being confided to a separate professor with a separate laboratory. Although Dr. Apjohn has hitherto discharged the duties of the chemical chair with great ability and with credit to the University, nevertheless, we can easily understand that the growth of the School of Physic in recent years has rendered indispensable the devotion of more time to medical chemistry than the interests of the arts and engineering students would allow of.

### The Standard of Milk Purity.

IF we were to put complete confidence in the report of Dr. Lankester, in his capacity of Medical Officer of Health to St. James's Westminster, we should find it difficult to understand how the prosecution of any milk dealer can be justified by analytical evidence, and we should be forced to the conclusion that in the article of milk, analysis is powerless to decide the question whether it be pure or not.

We find that Dr. Lankester has examined, within the year, 68 specimens of milk, not one of which he was able to declare to be adulterated, and only 14 of which were even "suspected." This would undoubtedly be a very gratifying condition of affairs if we were satisfied that the limit of adulteration and suspicion was fixed. We observe, however, that though Dr. Lankester found as much as 30 per cent. of cream in one sample of milk, 26 per cent. in another, and 13 to 15 per cent. in several others, yet he could only eliminate 7 or 8 per cent. of cream from many of the samples which he declares to have been unadulterated, and he does not label any sample as "suspected" until its richness falls below 5 per cent.

It would thus appear from Dr. Lankester's analysis that, though a rich specimen of pure milk may contain as much as 30 per cent. of cream, and an average specimen 15 or 18 per cent., yet the analyst cannot be sure that a sample containing only one-sixth of the quantity which a rich milk should contain is diluted. Dr. Lankester explains this unsatisfactory vagueness by pointing out that, although by analysis of a great number of specimens it is easy to say what is the quantity of butter, cheese, and sugar they contain, it is impossible to compel each cow to give the same quantities of these substances. It is a known fact that these substances will differ in almost every specimen of milk obtained from different cows, and from the same cow at different milkings.

We should be gratified to know whether, under any circumstances, an unsophisticated specimen of unskimmed milk could yield as low a percentage of cream as 4, for if such a condition be possible, it is incredible that any analyst can declare the presence of adulteration at all.

### Periosteotomy.

PROFESSOR HOUZE DE L'AULNOIT not only known as Surgeon to the Hôpital St. Sauveur at Lille, but also from the way in which he identified himself as Vice-President of the Central Committee for the northern part of France during the late war, has published an interesting work, which he entitles, under the category of "*Chirurgie Expérimentale*," *Etude Historique et Clinique sur les Amputations sous-périostées*. His system of operating in cases of amputation consists in substituting for the old method an entirely new one, to which he has given the name "*la Périostéotomie*," which means as follows: After the first incisions and flaps, say of a thigh, have been made by the operator, and properly retracted by the hands of an assistant, instead of the usual direction given in all surgical works and lectures—"with another sweep of the knife divide the periosteum"—he advocates the dissection upwards, by means of a bistoury, of the periosteum, and the formation of flaps of the same, so that when the limb has been removed these flaps can be made to form the immediate covering of the bone. Dr. Aulnoit advocates specially his system of "*Périostéotomie*" because the periosteum, having, in health, been in intimate connection with bone, becomes not only a bone protector, but also a bone-growth promoter, (if I may be allowed the expression) after such an important operation as the amputation of a limb.

Dr. Aulnoit gives interesting details of many cases from the battle-fields of the late war, as well as many others, in support of his new theory, which he is sanguine may be adopted everywhere.

### Visitation of Examinations.

THE visitation of examinations of the Medical Council, which gave rise to so much excitement this year, is to be continued during the coming winter, and twelve of the medical licensing bodies will come within the inspection—viz., the University of Edinburgh, St. Andrews, Aberdeen, Oxford, Cambridge, Durham, and London, the Colleges of Surgeons of London and Edinburgh, and the Colleges of Physicians of London and Dublin. We have reason to believe that new blood may probably be infused amongst the visitors, and that the Executive Committee are now engaged in selecting from a large number of names selected from the leading teachers of the three kingdoms.

### Homœopathic Moonshine.

WE hope the homœopathic fraternity will fully appreciate the following story, which is told by our able contemporary the *Pacific Medical*.

The *North American Journal of Homœopathy* is published quarterly by Boericke & Tafel, in New York, 145 Grand Street, in San Francisco, 234 Sutter Street, and by Henry Turner & Co., London and Manchester. The Editor is "S. Lilienthal, M.D., No. 230 West 25th Street, New York." We give these particulars to show that the

publication is of undoubted authority, and that the quotation we are about to introduce belongs to genuine homoeopathy. In the number for May, 1874, is an article from the pen of S. B. Higgins, M.D., Charlotte, N.C., entitled "Solar and Lunar Influence." The article appears among the original papers, without comment. Omitting a few paragraphs at the commencement, on the subject of the influence of moonlight on fishes, &c., we copy the rest of the paper literally, with italics just as we find them, leaving comment entirely to our readers.

"When the moon is nearly full, many persons who lie down in the open air, exposed to its rays, suffer pains and œdema of the parts exposed, on the ensuing day, and sometimes they lose their reason when the moonlight is concentrated on the head; hence, no doubt, the origin of the word "lunacy" or "lunatic," or misconstrued. I have treated several of these cases with the remedies recommended in the manuals, but never with rapid success till I had discussed the subject in my own mind awhile, and argued thus: If the moonlight *causes* the pain and œdema, there must be virtue in moonlight to *cure* it; so I exposed a glass half full of pure water to the direct and reflected light of the moon for three or four hours; at the end of this time I poured the water into a perfectly clean bottle, and shook it well for a moment or two. The next day I had a case of œdema of the face and hands, with violent pains in the swollen parts, of a neuralgic nature, in a stout negro, of about 35 years of age, who had slept the previous night in the open air, exposed to the rays of the full moon. I gave him about two ounces of the prepared water from the bottle marked "Luna" with directions to take a spoonful every hour till relieved—this at 8 a.m. At 12 m., and after having taken three doses of the *Luna*, he was relieved of all pain, and at 4 p.m. the œdema had entirely abated. After such marked success, I treated several similar cases with *Luna* with the same unvarying quick relief. Reminding my friend, the Doctor, of these cases, I asked him if he had noticed whether Mrs. N. N.'s sufferings were aggravated at the time of full moon. This he had not noticed, but made a note of it to report at a future conference. About a month later, we met one evening, and he said that two days previously (*the day after full moon*) Mrs. N. N. was taken suddenly with the most violent attack of metrorrhagia she had ever had, and her pains were most excruciating. Then, I replied, we must have found the key to the whole enigma; if I am right, moonlight causes the disease, moonlight will cure it—give her *Luna*. A glass was prepared that night and sent to her next morning, with directions to take a table-spoonful every hour till relieved; at the *third* dose the flow and pains ceased as if by magic. The ensuing month pains and flow presented themselves as usual, but *two* doses relieved entirely. A month later, pains and flooding again, but a single dose sufficed this time, and the month following menstruation was normal—no pains or excess of flow. Thus, this patient, after two years' suffering and agony, was restored to perfect health. Three years afterwards there had been no relapse. After her cure she remembered distinctly that every time she sat exposed to the moonlight at the full of the moon her sufferings were in every way aggravated; when she kept in the house at this epoch she suffered much less; now she sits exposed to the moonlight for three or four hours with impunity.

"We prepared *Luna*, and potentized it up to the 13th potency—a powder of which I have furnished to Dr. Samuel Swan, 13 West Thirty-eighth Street, New York, and it will soon be potentized up to the *cm.* potency by his new potentizing machine, just finished. I have used it for all cases of abnormal menstrual troubles which are aggravated at the period of full moon, at the 6th cent. potency, without having as yet to record a case of failure. Relating the preceding case to Dr. Swan, in December, 1872, he prepared some Sac. lac. by exposure to the concentrated rays of the sun, and has had this potentized by Dr. Fincke up to the *cm.*, and with different high potencies has cured several cases of headache where patients could remember having suffered at any previous time by

exposure to the sun. I believe that in such cases, which do not yield readily to other remedies, it will prove a specific, and, as such, of great value in our M. Medica. Dr. Fincke has potentized *Luna* up to the *cm.* potency; but this is from the moonlight in our climate, which, I think, may possibly be less powerful than the preparation I brought from South America; but as yet I have not had any opportunity of testing it so as to institute any comparison between the effects developed by the one and those developed by the other.

"Yours fraternally,  
"S. B. HIGGINS."

THE number of deaths resulting from the Norwich accident has now reached twenty-five. There are still one or two victims lying dangerously wounded.

MESSRS. CHURCHILL have issued their annual Red-Letter List, containing announcements of their forthcoming new works or new editions for 1874-75.

A STORY is current that the remains of Lady Dilke have been removed from London by her husband, Sir Charles Dilke, to Germany, for cremation.

THE Registrar-General reports during the week ending last Saturday 5,548 births and 3,168 deaths in 21 large cities and towns of the United Kingdom. The average rate of mortality in these towns was 22 per thousand.

THE marble statue of the Queen, sculptured by Mr. Noble for St. Thomas's Hospital, has been unveiled. It has been placed at the foot of the grand staircase. The statue was presented to the hospital by Sir John Musgrave, Bart.

By the will of the Rev. C. Awdry, late of Worthen, Salop, the Shrewsbury Infirmary receives £100. The Rev. Henry Jenkins, late of Stanway, Essex, has bequeathed £52 10s. to the Essex Hospital.

THE meeting of the Pharmaceutical Society of Great Britain will be held this evening, October 7th, at eight o'clock. The sessional prizes and certificates will be distributed at this meeting. An address to the students will be delivered by Mr. R. W. Giles, of Clifton. Ladies are invited to be present.

THE first meeting of the Harveian Society of London will take place at the Society's rooms on Thursday, the 15th instant, at 8 p.m., when the hon. treasurer, Mr. Henry Power, will read a paper "On Purulent Ophthalmia."

BEFORE the delivery of the inaugural address at St. Thomas's Hospital, on Thursday last, Sir Francis Hicks, the treasurer, said that at the annual distribution of prizes it was customary to reward such students as displayed most proficiency in surgery and anatomy with a prize, in the shape of a valuable gold medal. He was glad to announce that an accumulation of money had arisen from funds placed in their hands some years back, and arrangements were now pending for the founding of a gold medal, to be awarded on similar conditions as the other, to the most proficient student in medicine.

AND yet another edition of "Squire's Companion to the British Pharmacopœia" is announced—but twelve months since, and the ink was scarcely dry upon the ninth edition—an illustration of how a book sometimes sells. We should hazard a guess that there is not another medical book in the English language which sells at the rate of 2,000 copies per annum.

MESSRS. BAILLIÈRE, TINDALL, and COX have just published a large volume, royal octavo, giving names, addresses, and qualifications of the medical profession in America. This is the first medical directory that has ever been compiled for the States, and upon opening its well filled and well arranged pages, our only surprise is that such a go-a-head race as our cousins have the credit of being should have gone on so long without so valuable a book of reference.

DR. HARDWICKE, in a report on the health of Paddington, makes the following grave charge against the district: 'The deaths in young children are, as usual, very high—372 of total deaths, far too high, indicating some grave fault somewhere. 84 young children were taken off by measles, whooping-cough, and bronchitis, no doubt deaths all accelerated by undue exposure to cold while suffering from attacks of these complaints; 86 more deaths are from the consumption class; 29 deaths from violence, or accidental; 3 from suicide, and 3 from infanticide—these latter by persons unknown, who are thereby guilty of wilful murder of newly-born infants.'

## Literature.

### CLINICAL MEDICINE: LECTURES AND ESSAYS. (a)

WE begin our notice of this volume of lectures and essays by stating that the author had been formerly a pupil of the Meath Hospital, Dublin, and that the work is dedicated to Dr. Stokes. The volume itself is one of great merit, is pleasant reading, and is made up of a series of ten essays. Most of these are of great practical importance; but it may be well to notice them somewhat more in detail.

The first is "On the Treatment of Ulcer of the Stomach," and is an essay of much practical value. We need scarcely observe that this affection occurs chiefly in young females, and that the ulcer does not present any specific character. The main object of the author through the entire essay is to show the great value of complete rest, in order to allow the ulcer to heal; and to this end he dwells on the vast importance of keeping up the patient's strength solely by nutritive enemata, a formula for composing which will be found at page 24. During the use of these no food whatever is to be given by the mouth, and, as a general rule, the author states that from eight to ten days is quite sufficient to enable the ulcers to begin to heal. Then, and only then, very small quantities of the mildest food, such as milk, is to be given, and the quantity very gradually increased. By this plan, steadily carried out, the writer speaks of the certainty of getting this class of ulcers to heal; and in proof of this three cases are detailed, in which

there could be no reasonable doubt but that ulcers did exist, and did heal. Besides other symptoms, each of these cases had hæmatemesis. This seems to us conclusive of the nature of the cases, and the steadiness, and we would add rapidity with which the urgent symptoms yielded under the plan is very remarkable. Whilst placing rest in the very foremost place, however, the author does not ignore medicines, of which he chiefly speaks of opium and bismuth as being each most valuable in their way. We may add that the cases are very well detailed, and, as far as was known, the cures were permanent.

Though the second essay is a valuable one, it has not the interest of the last. It is "On Cyanosis from Patent Foramen Ovale." In one sense this is a rare affection, and yet we must be prepared to answer all that is known about it, and even to prescribe for it. In the vast majority of cases the arrest of development is permanent, and nothing beyond temporary relief can be afforded. In one instance, however, given by the author, where the affection was quite marked at birth, it disappeared at the end of some weeks. This child was one of several where the affection showed itself in the same family, and yet some of them were born quite healthy. This, in itself, is a remarkable fact, and the history of this family, as given by the author, will well repay perusal. We may add that the medicine from which the children got the most marked relief was the peroxide of hydrogen, first brought into notice by Richardson.

The third essay is "On the Use of Ether in the Treatment of Phthisis." We need not dwell long on this subject. In the course of some enquiries into the nature of phthisis, the author was led to think that the pancreatic juice was often deranged, and that, according to Brown-Séquard, ether had a specific effect in altering and improving the secretion. Hence our author was led to use it, at first in an ordinary mixture, and finally, in combination with cod-liver oil. The results in our author's hands would seem to have been very encouraging, and much beyond what could be gained from the oil by itself. We ourselves have tried the combination of the two drugs, but we have not been able to satisfy ourselves that there was such a marked difference in the results. That the effect of the ether is to stimulate the pancreas is, we think, very probable. But in different cases the taste was so unpleasant that the patients begged it might be given up.

The fourth essay is "On Digitalis in Heart Disease." This is a subject about which, it appears to us, there still hangs much obscurity. Not that we doubt for a moment the great power and efficacy of the drug; but that we are forced to question the theories on which its action is said to depend. It has appeared to us that in an inquiry of this kind much more precision is required than has yet been given to the question. Thus, there can scarcely be a doubt but that the different preparations of the drug act differently the one from the other. We recollect reading a paper many years since in which it was stated the effects of the tincture were very different from those of the infusion; and, if we are not mistaken, the powder has the most special claims on our attention from the same point of view. Again, we observe that the doses of the drug are not as defined as, it appears to us, they ought to be. We know of course that different patients will bear different doses; but making allowance for this, much more exactness may, we believe, be attained. Our author, p. 94, speaks of using one to three drachms of the infusion three times a day. The dose in the British Pharmacopœia is given at two to four drachms. Hence we conclude that four drachms is a perfectly safe dose, and further, that our author has not used the drug so as to ensure its full effects. If we recollect right, this was not the way Withering acted, but that in most, if not all his cases, the full physiological effects of the drug were produced. We are quite aware that exception may be taken to this line of argument, but we feel sure enough has been advanced to prove the object of our remarks, which is, that if we wish to ascertain the real powers of a drug like digitalis, we must conduct our experiments in a more exact and defined way

(a) "Clinical Medicine: Lectures and Essays." By Balthazar Foster, M.D., Fellow of the Royal College of Physicians, Professor of Medicine in Queen's College, Physician to the General Hospital, Birmingham, Consulting Physician to the West Bromwich District Hospital, &c. London: J. and A. Church, 11, New Burlington Street, 1874. Pp. 864.

than has yet been done. We observe our author commences this essay by stating the great differences of opinion which have existed as to the effects of this drug; and we believe that some at least of these difficulties will be lessened by following out our suggestions. Our own direct experience goes to prove the great value of the medicine in cases of mitral stenosis, and chiefly when the beat of the heart is weak and irregular, the extremities cold and blue, and the dyspnoea urgent. We entirely concur, too, with Peacock, that the diuretic effect of the drug has of late been quite too much overlooked, and, if our memory do not fail us, it was this effect which is so admirably illustrated in the work of Withering. The subject is too large, however, to follow further here, nor, indeed, will our limits allow us to do much more than name the remaining essays of the volume before us.

The fifth essay is "On Rupture of the Aortic Valves from Accident." The cases given are of much interest, and go to confirm the fact that in certain states of the constitution and from over-exertion one of the aortic valves is liable to rupture, which, sooner or later, leads to a fatal result. For ourselves, we do not believe that such an accident will occur in a perfectly healthy man.

The sixth essay is "On the Synthesis of Acute Rheumatism," and we must say it proves to demonstration that, in some instances at least, if not in all, this disease is due to an excess of lactic acid in the system. For the proof of this important fact, which many, and, amongst the rest, the author himself, doubted, we must refer our readers to the essay itself.

The seventh essay is "On Duchenne's Paralysis," and is one of much interest. It scarcely admits of doubt but that this affection is of a specific kind, and, as such, requires to be distinguished from other diseases with which it has more or less analogy. It has not chanced to ourselves to meet any example of the affection. It is worthy of noting that two of the examples given occurred in the same family. It does not appear that treatment has in any instance been successful. Some of the cases detailed are illustrated by engravings.

The eighth essay is headed "Observations on Diabetes Mellitus and its Treatment." This essay is probably the most elaborate of the whole series. The reader will find in it many new views on the subject, and the great importance, in a clinical point of view, of separating the disease into different classes. From the number of cases given by the author we get the impression that the disease is much more common in England than with us in Ireland. Hence the importance of the divisions of the disease which the author has made. Thus, it appears that, while in some instances an exclusively animal diet causes a great diminution of the sugar, in others the same result is not obtained; and, again, an analogous effect has been observed as regards the effects of medicines, for in some of the cases one medicine did good, whilst with others it completely failed. We consider these points as to diet and medicines in relation to the treatment of diabetes as of much importance, and as tending to remove, and in a very marked degree, some of the difficulties which surround the subject. We must refer our readers to the essay itself for the details to which we have alluded, and would only mention here, that amongst other means which the author tried was the peroxide of hydrogen—a medicine introduced, as we before stated, by Richardson, and which seems to produce very specific effects on the human frame. We may notice, too, a fact on which the author dwells—viz, that in the cases of the most severe forms of diabetes, where the wasting went on with great rapidity, yet in these very cases the temperature kept steadily below the healthy standard. We must leave to others the explanation of this erroneous phenomenon, as well as other points of much interest detailed in this essay.

The ninth essay is entitled "Cases Illustrating the Use of the Sphygmograph and Cardiograph in the Study of Diseases of the Heart and Great Vessels." This essay is also very elaborate, and illustrated by the details of several cases of much interest. Case 3 struck us as one of

peculiar importance. It is given at some length, and, besides the presence of disease of the aortic valves, had also an aneurism of the left subclavian artery. The tracings of the two radial pulses exhibited a marked contrast the one to the other. The autopsy, it may be added, confirmed the points of diagnosis which had been made out during life, as also the exact situation and state of the aneurism, which we may also observe had led to considerable wasting of the arm. The entire essay will well repay perusal.

The tenth and last essay is "On a Case of Pleuritic Effusion, in which Embolism followed Thoracentesis by Aspiration." This is a case of great interest. The patient, a man of 26 years of age, had suffered from right pleural effusion for several months, and was finally obliged to enter hospital and have the fluid drawn off to the amount of 130 ounces. Within three days the patient was seized with pain in the calf of one leg, and this was followed by symptoms of obstruction of the artery, and then signs of gangrene of the limb. The other limb was then attacked in the same way. The renal secretion became very scanty for some days, and though this improved again, the general symptoms did not, and the patient died about twelve days after the chest had been tapped. Embolism, which the author traced to the pulmonary veins of the compressed lung, was formed, and in a very marked degree in the different arteries where mischief was shown during life, as also in the kidneys and spleen. There were traces, too, of tubercle, both on the peritoneum and the surface of the pleura. The remarks of the author on this rare case are of interest. He naturally regrets that the effusion had not been removed long before; and there was certainly every reason to suppose that, had it been earlier done, the man's life would have been saved. But we cannot pursue the subject further here.

We have now given the very briefest sketch of the several essays of which this volume is made up. They are all characterised by good sense, by acute observation, and, as far as we know, a thorough knowledge of the matters in hand, and we have no hesitation whatever in recommending the volume to the notice of our readers.

#### MEMORIALS OF THE LIFE OF JAMES SYME. (a)

THE life of the late Prof. Syme is full of interest to the lover of his profession, and this volume of memorials has no doubt been eagerly perused by thousands of his admiring pupils. To them it will recall vividly some of the traits of their master, and its incidents will bring to their memory passages of his life of which they have often talked together, for Syme so interested his pupils that his personality was always a pleasing subject of conversation among them, and through them the outer world—medical—has been filled with rumours of his powers and of his goodness. His ability in diagnosis—though few will deny that ever he made serious mistakes—his skill as an operator, his wondrous coolness, his patience, his daring, his abundant resources—are not all these engraved in the memory of the admirers of surgery by the numerous anecdotes circulated by his pupils. Nor was he less remarkable for the kindness, hospitality, and nobility of purpose which are seen in his character. His determination and—shall we call it his self-will?—led him to take a very prominent part in Edinburgh controversies. Some of these were of a painful kind, and we could wish the author had not dwelt upon them; they detract from the general picture of the man too much, for they were, after all, only episodes in a life mainly devoted to the practice and teaching of surgery.

Syme excelled as a writer as well as a *viva voce* teacher, and excelled in the way that medical men so much affect, and yet so much fail in. He was terse and exact, but destitute of ornament. There are, no doubt, books, espe-

(a) "Memorials of the Life of James Syme, Professor of Clinical Surgery in the University of Edinburgh, &c." By Robert Paterson, M.D., Vice-President of the Royal College of Physicians of Edinburgh, &c. Edinburgh: Edmonston and Douglas. 1874.

cially of the didactic kind, that are best thus written, and Syme was a master of this manner. He, however, was neither dry nor stilted, faults too common with medical writers, and frequently discernible in criticisms. Some reviewers, in fact, have quite the habit of denouncing an easy flowing style as "fine writing," an offence they are themselves incapable of committing. If they would study Syme they would see that, though terse, he was fresh, and therefore, reading his papers did not weary. We should have been glad if his biographer had approached him in this.

Syme was reluctant to admit the merit of novelties—slow to believe; hence, he was not always just to his compeers, as witness the case of acupuncture. If Simpson was not likely to be easily credited by Syme, the same suspicion does not hold good of other operations, and we must therefore admit that Syme did not do full justice to others. This defect in his conduct was only atoned for by the marvellous merit of his own career. It is much to be regretted that two such men as Syme and Simpson should have spent so much of their lives in academic squabbles that tarnish their fame and were unworthy of *alma mater*. Those at a distance probably judge these misunderstandings more severely, and at the same time more justly than those who were in any degree mixed up in them. We should have been better pleased with this biography had it dwelt less upon these matters, and spoke of them more in the tone of Dr. Duns, in his biography of Simpson; but for the other portions of Dr. Paterson's work we are grateful, and his labours will serve to aid some future author to draw a life-like picture of the great Edinburgh surgeon. Perhaps at present it is almost too soon; but no one doubts that Syme will live in medical history as a surgeon and as a teacher of wondrous power; while in the present generation his example and his practice are exercising an amazing influence, which will largely descend to the next; for few who have been under his spell will fail to transmit some of its power to their pupils and successors.

#### MEADE'S MANUAL OF PRACTICAL MEDICINE. (a)

THE contents of the old "Meade's Manual" were grouped under three heads—physiology, pathology, and therapeutics. This arrangement has been retained by the editor of the new edition, but the second part has grown so much that it is as a manual of practical medicine that the work must be judged. The other parts are confessed to be mere sketches. That of physiology may serve the purpose of some students, to look up as they would their notes; but it is almost to be regretted that the space is thus occupied which might be added to medicine. Admitting, however, that the physiology is a good introduction to the medicine, we cannot say as much for the closing part on therapeutics, and we would advise in a future edition, to which Dr. Silver may reasonably look forward, the rejection of this part, which will give him more scope. This brings us to the main part of the book. It is a manual for practice, and a small one; it does not, therefore, profess to be exhaustive, nor to give references. We believe it is fairly accurate, and likely to be useful. Diseases are sketched briefly, and then the treatment is stated. This is laid down somewhat dogmatically—necessarily so, since it would be absurd in such a brief manual to enter upon differences of opinion. We have found as a rule that the treatment recommended is sound and safe, so that the manual may be used as a guide. There are, however, passages of which this cannot be said—thus, at p. 228, under the head "Laryngitis," it is said: "Nitrate of silver is best applied in strong solution (sixty grains to the ounce) by tying a morsel of lint or cotton-wool to the end of a penholder." It is not said what is to be done with the penholder; but the student will presume he is

to dip the armed end into the solution and introduce it into the larynx. Fortunately for the patient, he will not succeed in doing so; but the attempt is dangerous. In these days the method spoken of seems antiquated—not to say barbarous, and we suspect may be a remnant of the old edition which has escaped Dr. Silver's notice.

There are not many blots of this kind in the work, which will be found a very useful manual to many students who possess larger treatises on the subject but desire a portable text-book.

#### PHARMACEUTICAL CHEMISTRY. (a)

CERTAINLY students of pharmacy cannot complain of a dearth of literature devoted to their special wants. Of late years there has been an avalanche of books—good, bad, and indifferent—devoted to pharmaceutical science, and we suppose that the supply has been in answer to a demand. We would classify Dr. Muter's production under the head of good books. The first chapter in the book is devoted to an exposition of the modern theories of chemistry, and we commend it as a lucid, forcible, and concise statement of a subject fraught with difficulties for commencing students.

In the second chapter the practical processes concerned in chemical action are described. In most chemical textbooks the salts of the metals are described under the heads of their basylous radicals; Dr. Muter adopts a very different plan, and one which must greatly assist the student's memory. He treats first of the source, character, means of isolation, and mode of detection of the principal metallic elements, including hydrogen among them. A brief consideration of the compound basylous radicals follows the study of the simple basylous radicals. The simple acidulous radicals are next treated of, and the combination of each of these with the basylous radicals are fully described; by this means the different oxides, chlorides, &c., are compared.

We have said enough to afford an idea of the scope and mode of arrangement of Dr. Muter's work. Tabular matter and bold and striking type are characteristics of the book; the author has evidently been actuated by an earnest desire to lighten the labour and to assist the memory of the student. No book is faultless; but the errors in Dr. Muter's book are not of such magnitude as to call for special censure, except at the hands of very captious critics.

Dr. Muter leads a busy life; as principal of a flourishing school of pharmacy, his every hour is well nigh occupied; we cannot, therefore, withhold our admiration for his capabilities for hard work when we have such an evidence of it as in this book of his. There is about it an air of concentrated energy and uncompromising intensity of purpose which cannot fail to arrest the attention and to enlist the sympathy of every honest student.

## Correspondence.

#### THE PUBLIC HEALTH (IRELAND) ACT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR

SIR,—The first stage in the working of the new Public Health Bill having been now completed by the selection of the officers, the next is to apportion their salaries, and this has been, I believe, almost universally deferred for a week or two for purposes of consideration, or, possibly, communication with the higher powers.

It is to be hoped that, in the interval, all parties concerned will remember that, as far as the medical officers are concerned, the new duties to be imposed on them are in diametrical opposition to their own interests, and that the more successful they may be in carrying out the objects of the Bill, the worse it will be, not only for themselves, but for every member of the profession in their districts.

(a) "Practical Medicine, with a Sketch of Physiology and Therapeutics," being the Fourth Edition of Meade's "Manual for Students." By Alexander Silver, M.A., M.D., Physician to Charing Cross Hospital, &c. London: H. Baillière. 1874.

(a) "An Introduction to Pharmaceutical and Medical Chemistry." By Dr. John Muter, M.A., F.G.S. London: Published by the South London School of Pharmacy, Keatinge Street, London. Simpkin and Marshall.

In no other instance is a professional man called on to act to his own certain disadvantage for the benefit of the public. We never have heard, and never shall hear, of a lawyer or attorney being employed by the public for the purpose of going about among the people and persuading them to settle their disputes amicably so as to prevent law-suits. Yet this is exactly what the medical officers of health are expected to do under this Bill; for the more they exert themselves to abate nuisances injurious to health the more do they take the ground from under their own feet, and the bread out of their own mouths. And it is not only in this respect that the faithful exercise of their new functions will be injurious to them, because it must of necessity entail upon them the enmity of everyone who is called upon to make any expensive change in the arrangements of his residence, or in the habits of his life, and enmity to a medical man is simply ruin.

Thus, the duties imposed on these officers are calculated to be injurious to them in direct proportion to the efficiency of their performance, and are also in their nature highly invidious and unpopular, circumstances likely to be overlooked, but which imperatively demand the serious consideration of those who are now called on to allot an adequate remuneration to these gentlemen, without whose self-sacrifice and disinterested assistance the Act will be nugatory, and the Bill on which so much time, trouble, and legislative talent has been expended, nothing but mere waste-paper.

Of course, as usual, it may be expected that the guardians will count on the known honour and probity, as well as public spirit of the profession, and on the competition which exists among its members; but in this case they may be reckoning without their host, for they may be perfectly certain that no men will perform invidious and disagreeable duties with either zeal or efficiency if they have reason to feel disgusted with the discouraging idea that their services are not properly appreciated.

### DR. LYON PLAYFAIR ON HEALTH.

On Monday the Social Science Congress met at Glasgow, the hall being crammed to hear the opening address of Professor Playfair on Public Health. Cleanliness, said the speaker, is allied to health and happiness as much as to Godliness. Scotland must be one of the dirtiest nations in Europe, for its death-rate is very high and is steadily increasing. In the urban and rural districts in the small towns the rate is as high as it is in London. In the large manufacturing towns from eight to nine persons in every thousand die annually in excess of the metropolitan rate. Over the whole country about 125,000 of the population perish every year who would not perish if the laws of health were obeyed. Scotland, he hinted, had barely yet emerged from the groove of thought regarding pestilence, fever, ague, dirt, and general disease which was universal in Europe for many hundred years. When the Egyptian, Greek, and Roman civilisations expired, with their baths and divine maxims about ablutions and purifications, dirt reigned for a thousand years. Not a man or woman in Europe ever took a bath; hence the spotted plagues, the black deaths, the sweating sicknesses, the dancing manias, the mewing manias, and biting manias that ravaged the people and cut off in the Middle Ages one-fourth of the entire population. Religion came to the aid of dirt; the more filthy a saint was the more saintly he was considered. Some of the hermits never changed their clothes, and only combed their hair once a year. St. Anthony never washed his feet, and St. Thomas A'Becket's under garments acquired an additional sanctity from the vermin they contained.

## Medical News.

**Hospital Saturday.**—A meeting in support of this movement was held at Guildhall on Saturday afternoon. The Lord Mayor presided, and, in opening the proceedings, said that the movement must commend itself to every right-minded and right-thinking man. They were all desirous of relieving affliction, and of giving something tangible towards the

alleviation of the suffering poor. It was a fact that many working men did not attend any places of public worship on a Sunday. Saturday, the 17th of October, would be the day on which those men could contribute on behalf of the hospitals. Hospital Saturday had for years been an institution in Glasgow, Manchester, Liverpool, Birmingham, and other large towns. He had been informed that it existed even in Melbourne (hear, hear). Charity, kindness, and benevolence were endless themes to dilate upon—they were the bonds which tied the best of men together, and it was the practice of these virtues which alone made the world enjoyable to live in (hear, hear). Captain Mercier next addressed a few remarks explanatory of the movement to the meeting. He was followed by Mr. George Savage (secretary to the Working Men's Club and Institute Union), who stated that Hospital Saturday had the recognition of the public. There were over 80 hospitals and dispensaries in the metropolis, and the persons annually relieved through their agency amounted to nearly one-third of the population of the metropolis, and their expenses amounted to £600,000 per annum. Mr. Kenny (Labourers' Union) gave statistics of hospital work, and said that last year the hospital revenues left a deficit of £40,000 to be made good. He calculated that there were 750,000 adult workmen in London, and a subscription of one half-penny each per week, which any of them could spare, would produce £80,000 per year. The Rev. Cannon Miller, Mr. E. Gray (Paviors' Council), Mr. Shrivess (Carmen's Association), Mr. Hawkins (Post Office), Mr. H. N. Hoare (treasurer to the fund), Mr. Watkinson (Boiler Makers' Association), Mr. W. R. Petty (an *employé* of the Great Western Railway), and Dr. Vincent Ambler also addressed the meeting.

**The London School of Dental Surgery.**—On Monday afternoon Mr. W. Scovel Savory, F.R.S., presided at the distribution of prizes in the new building of the Dental Hospital, and delivered a lengthy and able address upon the history, progress, and prospects of dental surgery before a crowded and appreciative audience. The prizes distributed were as follows:—Mr. Tomes' prizes: Mr. Hepburn, Mr. Gibbings, Mr. Bryant, and Mr. W. S. Bennett; Mr. Makins' prize to Mr. Pearman; Mr. Turner's prizes to Mr. F. J. Bennett and Mr. W. S. Bennett; Mr. Cartwright's prize to Mr. Bryant. An announcement was also made that a new scholarship in dental surgery had been instituted by Mr. Saunders for competition amongst students of the hospital. Cordial votes of thanks to Mr. Savory and the gentlemen who had given the prizes closed the proceedings.

### NOTICES TO CORRESPONDENTS.

**MEDICAL MICROSCOPICAL SOCIETY.**—The Opening Meeting of the approaching Session of the Medical Microscopical Society will take place at the Royal Westminster Ophthalmic Hospital on Friday, the 10th inst., at 8 p.m.

**THE FEMALE MEDICALS.**—The *Academy* says—"Those who sympathise with the cause of female medical education will be glad to hear that a college has been opened for the purpose in Henrietta Street, Brunswick Square. The premises are very convenient, and there is a large garden in which the dissection-room can be placed, so as to avoid everything disagreeable to the neighbours. The council includes the names of Mrs. Garrett-Anderson, Dr. Billing, Dr. Elizabeth Blackwell, Dr. Buchanan, Dr. Charlton Bastian, Dr. King Chambers, Dr. Cheadle, Mr. Critchett, Mr. Ernest Hart, Mr. Berkeley Hill, Professor Huxley, Dr. Hughlings Jackson, Dr. Murie, Mr. A. Trehern Norton, Dr. Payne, Dr. W. S. Playfair, Dr. Burdon Sanderson, and Dr. Sturges."

**A FORMER PUPIL.**—The age of the late Dr. Jacob was 84, not 85, as accidentally mentioned by the contemporary referred to.

**MR. R. JEX CRICKMER.**—The date of your wonderful experiments and discoveries have been duly noted in our diary. Should the world hereafter decide upon erecting a suitable memorial we shall be proud to supply particulars.

**ACCIDENTS.**—A little pamphlet has just been issued by the Accident Insurance Company, which, in view of the many accidents of recent occurrence, has a peculiar interest. We give a few comparative statistics showing the number of compensated cases during the last two years: The horse accidents are 361 as against 321 in the previous year; business accidents 245 as against 237; house accidents 147 as against 141; field accidents number the same as last year, 44; street accidents have been fewer, only 87 as against 113 in 1872. A slight increase in the number of railway accidents appears—viz., 89 as against 35; tramway accidents were for the first time developed in the list for 1872 in 2 cases; this year there are 5; cricket accidents have been more numerous, while a general average amount of compensations seems to have been paid for the many other casualties through cattle, dogs, cats, rats, ferrets, fowls, fire, machinery, boating, football, shooting, &c.

### BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

The West Riding Asylum Medical Reports. Vol. IV.

On the Right Use of Disinfectants. By Henry Letheby, M.B.

A Microscopical and Chemical Examination of Certain Waters. By Jabez Hogg and Dugald Campbell.

Bad Wildungen und Seine Miner Alqueellan. Hamburg.

Annual Report of Health. By Dr. Dendfield.  
Boston Medical Journal. British Journal of Dental Science. The Monthly Microscopical Journal. The Psychological and Medico-Legal Journal. Medical Temperance Journal. Journal of Mental Science. The Obstetrical Journal. Westminster Review, &c., &c.

#### VACANCIES.

Ballyshannon Union, Kinlough Dispensary District. Medical Officer. Salary, £100 per annum, exclusive of fees. (See Advt.)  
Mohill Union, Ryann Dispensary District. Medical Officer. Salary, £120 per annum, exclusive of fees. (See Advt.)  
Stranorlar Union Dispensary District. Medical Officer. Salary, £100 per annum, exclusive of fees. Applications to be addressed to Mr. Gunning, Hon. Sec. (See Advt.)  
University College, London. Professorship of Comparative Anatomy and Zoology. Full information of Mr. Robson, at the College.  
St. Marylebone, London. Medical Officer for the Christ Church District. Salary, £230 per annum. Application to be made to the Clerk, at the Union Office.  
Dental Hospital of London. Dental House Surgeon. Salary, £40 per annum. Hours, 9 till 2, daily. Applications to the Hon. Sec.  
Parish of Lambeth, Surrey. Resident Medical Officer and Dispenser for the parish Infirmary. Salary, £100, with board, &c. Candidates should address the Clerk to the Guardians at the Union Offices.  
Stockwell Fever Hospital. Assistant Medical Officer. Temporary only, at £3 per week, with board and lodging. Candidates must present themselves before the Committee, at the Hospital, on Friday next, at 3 o'clock.  
Ramsgate Dispensary. Resident Medical Officer. Salary, £100, with furnished apartments. Applications to the Secretary.  
Tunbridge Wells Dispensary. House Surgeon. Salary, £100 per annum, with board and lodgings. Applications to the Secretary.  
Martley Union. Medical Officer for No. 4 District. Salary, £85, with fees extra. Applications to Mr. Knott, Solicitor, Worcester.  
West Bromwich Hospital. House Surgeon. Salary, £50, with board and residence. Address the Secretary.

#### APPOINTMENTS.

ARMSTRONG, H. G., M.R.C.S., House Surgeon to the Royal Berkshire Hospital, Reading.  
CUNNINGHAM, J., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the West District of the Belford Union Workhouse, Northumberland.  
DUNLOP, WM., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer of the Union Hospital, Consulting Sanitary Officer for Letterkenny Union.  
FAOGE, H. W., M.R.C.S. Ed., Medical Officer of the No. 1 District and the Workhouse of the Lutterworth Union.  
GRAMSHAW, F. S., M.D., Medical Officer for the Stillington District of the Easingwold Union, and Medical Officer of Health for the Stillington Sub-district of the Easingwold Rural Sanitary District.  
LAWTON, M., L.R.C.P. Ed., L.R.C.S. Ed., a Medical Officer for the Midleton Dispensary District of the Midleton Union, co. Cork.  
MIDDLETON, W. H., L.R.C.S. I., L.K.Q.C.P.I., Medical Officer to the Westmeath County Infirmary, Mullingar.  
MOORE, E. W., L.R.C.P. L., M.R.C.S. E., Medical Officer of Health for the Twickenham Urban Sanitary District.  
PARRY, T. S., M.R.C.S. E., Resident Medical Officer's Assistant and Senior Clinical Assistant to the Brompton Hospital for Consumption.  
SHAW, R., M.B., C.M., Parochial Medical Officer and Public Vaccinator for Dailly, Ayrshire.  
STEWART, D., M.B., L.R.C.S. Ed., House Surgeon to the Blackburn and East Lancashire Infirmary.  
WHITE, W. L., M.B., C.M., House Surgeon and Superintendent to the Southport Convalescent Hospital and Sea-bathing Infirmary.  
WIBLIN, J., L.R.C.P. Ed., F.R.C.S. E., Medical Inspector of Passenger Ships at the Port of Southampton.

#### Marriages.

BROOKHURST-GREAVES.—On the 30th ult., at St. John's Church, Hackney, T. H. Brookhurst, M.R.C.S., of Holmes Chapel, Cheshire, to Caroline Mary Edith, eldest daughter of the late G. Greaves, F.R.C.S., of Manchester.  
FENTON-MARRIOTT.—On the 20th ult., at St. Michael's Church, Coventry, Mary Anthony Fenton, M.D., of Stranahely, co. Wicklow, to Martha Jane, eldest daughter of James Marriott, Esq., J.F., of Coventry.  
STEVEN-JACOBSON.—On the 29th ult., at St. George's, Hanover Square, W., Alexander Steven, M.D., of Glasgow, to Alice Woolf, second daughter of N. W. Jacobson, Esq.

#### Deaths.

BLACSTONE.—On the 1st October, at 1 Gloucester Road, London, N.W., Joseph Blackstone, M.R.C.S., aged 73.  
HUNT.—On the 2nd September, Richard T. Hunt, M.R.C.S.E., of Disley, Cheshire.  
LOMAX.—On the 16th September, H. I. Lomax, L.R.C.P. Ed., of Chaddle, Cheshire, aged 62.  
MANN.—On the 21st September, C. W. Mann, M.R.C.S.E., of Bridlington Quay, aged 63.  
ROBINSON.—On the 21st September, C. H. Robinson, M.D., of Stockport Road, Manchester, aged 32.  
TATE.—On the 23rd September, at Ruyton Lodge, Fareham, Hants, George Ralph Tate, M.D., late Royal Artillery, aged 39.  
TROTTER.—On the 2nd October, at 58 Old Elvet, Durham, John Trotter, M.D., in his 70th year.

**MEDICAL—WANTED,** an ASSISTANT to the APOTHECARY PROFESSION of two or three years' standing, who understands the Compounding and Dispensing of Physicians' Prescriptions.—Apply to ALEX. BRIN, Armagh.

**IRISH PRACTICE.**—A Medical Gentleman can be secured in a PRACTICE unopposed in one of the most picturesque parts of Ireland. Appointments about £250 per annum. Large convenient House, Offices, walled-in Garden, and from two to fifty acres of land, as may be agreed upon. House and portion of land can be purchased (or rented).—Address D. Y., 23 Ely Place, Dublin, where an interview can be had.

**TO MEDICAL MEN, DENTISTS, &c.**—The Widow of a professional man wishes to let a Dining-room Floor (two reception rooms) in a superior house a few doors from Russell Square.—63 Guilford Street, London, W.C.

**IRISH PRACTICE.**—A Medical Gentleman can be secured in an easily worked Practice, realising at present £300 a year, but which can be immediately doubled. Good house, office, &c., at low rent. Satisfactory reasons for present Incumbent leaving. Terms moderate.—Apply MEDICUS, 23 Ely Place, Dublin.

#### MOHILL UNION.

##### RYNN DISPENSARY DISTRICT.

The COMMITTEE of MANAGEMENT of the Ryann Dispensary District will, at a Meeting to be held at Tarnaght Dispensary on TUESDAY, the 20th OCTOBER, 1874, at 12 o'clock, proceed to elect a properly-qualified

**MEDICAL OFFICER** for the District, at a Salary of £120 per annum, exclusive of Registration and Vaccination Fees.

Applications, with Testimonials, &c., to be forwarded to me on or before 12 o'clock on the above-named day.

Personal attendance of Candidates will be required on the day of Election.

By order of the Committee,

FRANCIS GEARTY, Hon. Secretary.

Finloughla, Dromod, 29th September, 1874.

#### BALLYSHANNON UNION.

##### KINLOUGH DISPENSARY DISTRICT.

The COMMITTEE of MANAGEMENT of the above Dispensary District will, at their Meeting on 8th OCTOBER next, at 3 p.m., proceed to elect a properly-qualified

**MEDICAL OFFICER** for the District, in room of JOHN WELSH, Esq., M.D., resigned, at a Salary of £100 per annum, exclusive of Vaccination Fees.

Applications, accompanied by Diplomas, &c., will be received by the Hon. Sec., R. St. G. Johnston, Esq., Portmarnon, Ballyshannon, up till 10 a.m. on the above day.

Personal attendance of Candidates required.

By order,

J. B. CHISEN, Clerk of Union.

September 26th, 1874.

#### STRANORLAR UNION.

##### STRANORLAR DISPENSARY DISTRICT.

**MEDICAL OFFICER WANTED.**—In consequence of the resignation of Dr. WALLEN, the Managing Committee of the above district will, at an ordinary meeting to be held at the Workhouse of the said Union on MONDAY, the 12th day of OCTOBER next, proceed to elect a MEDICAL OFFICER, at the Salary of One Hundred Pounds per annum, exclusive of Registration, Vaccination, and Sanitary Fees.

Application from Candidates, with Testimonials showing that they possess the qualifications prescribed by the regulations of the Local Government Board, will be received by me up to 12 o'clock that day. Candidates to be in attendance on the day of election.

The Medical Officer will have to reside at Stranorlar.

By order of the Committee,

JOHN GUNNING, Hon. Secretary.

**DUBLIN INFIRMARY for DISEASES of the EYE and EAR, Ely Place.**

#### Ophthalmic and Aural Surgeon:

ARCHIBALD HAMILTON JACOB, M.D. Dub., F.R.C.S., Ex-Ophthalmic and Aural Surgeon to the City of Dublin Hospital.

#### Consulting Physician:

EVORY KENNEDY, M.D. (Hon. Caus.) T.C.D. and Edin., Fellow and Ex-President King and Queen's College of Physicians.

#### Consulting Surgeon:

GEORGE H. PORTER, F.R.C.S.I.; M.Ch. T.C.D. (Hon. Caus.), Surgeon in Ordinary to Her Majesty the Queen in Ireland; Fellow and Ex-President, R.C.S.I.; Senior Surgeon to the Meath Hospital.

#### Obstetric Physician:

JOHN CRONYN, M.D., F.R.C.S., Examiner in Midwifery, Roy. Col. Surgeons; Ex-Assistant Physician Rotunda Hospital.

Work, Income, and Expenditure for Twelve Months, ending June 30, 1873.

Annual number of Dispensary patients	...	...	729
Number of visits paid by such patients	...	...	5,847
Number of patients within the Infirmary	...	...	134
Number of operations performed	...	...	163
Total gross expenditure per bed per annum	...	£27	15 0
Average expenditure per intern patient	...	1	10 6

The Infirmary is wholly dependent on private benefactions, and is in debt to the Medical Officer. SUBSCRIPTIONS ARE EARNESTLY REQUESTED

## Original Communications.

### ON THE SCIENTIFIC AND EMPIRICAL INVESTIGATION OF EPILEPSIES. (a)

By J. HUGHLINGS JACKSON, M.D., F.R.C.P.,  
Physician to the Hospital for the Epileptic and Paralyzed, and to the London Hospital.

#### CHAPTER I.—PART I.

##### INTRODUCTORY.

So many books have been written on epilepsy that it may seem rash to add another; but, as I have studied epilepsy, epileptiform seizures, and many other diseases of the nervous system for some years with great care and labour, there is no impropriety in putting forward some of the conclusions I have arrived at. I have, however, already written so very many papers on the subject that

(a) This and subsequent chapters to be published in this journal are the introductory chapters of a forthcoming work on Epilepsy.

I must, to prevent misunderstanding, at once remark on one matter which will be considered more fully towards the end of this chapter, and at great length in future chapters. Throughout this book the functions of the Cerebral Hemisphere are assumed to be the Co-ordination of Impressions and Movements. The co-ordinations which the very highest centres in the hemispheres effect are only in great degree different from those of the lowest nervous centres. This does not exclude the other so-called "functions" of the cerebral hemisphere, "ideation," "consciousness," &c. Sensori-motor processes are the physical side of, or, as I prefer to say, form the anatomical substrata of, mental states. It is with these substrata only that we are directly concerned in an inquiry like the present.

For some years I have held the view above stated—viz., that the whole of the cerebrum is, like lower centres, made up of processes representing impressions and movements. I have stated it in innumerable places, especially with regard to Speech. I consider that this view accords with and is confirmed by the results of the now well-known experiments of Hitzig and Ferrier. With regard to Speech, Ferrier has recently, by independent investigation and from a different kind of evidence, come to conclusions essentially like mine.

what I am now about to write will, in essential matters (method and main conclusions), be a recapitulation. But this, assuming that what I have to say on epilepsy has any importance, is almost a sufficient reason for writing a book about it. The papers written during more than ten years are inconveniently scattered in volumes of Reports, in Journals, &c. Again, the work I have done on the subject is to be found in papers where many would never, from the titles of those papers, look for it. This has been the result of my way of investigating. I have studied epilepsy and epileptiform seizures on a novel method, and have written on it from widely different points of view. Besides studying in minute detail such cases as would ordinarily be called idiopathic, or true epilepsy, I have sought out for study simpler cases, or, let me say, until I give my definition of epilepsy, cases of epileptiform convulsion, and especially those complicated with other definite nervous symptoms. For I have long been convinced that "idiopathic epilepsy" is far too difficult a subject for precise investigation unless we approach its consideration from the basis supplied by the principles deduced from less complex kinds of cases. Hence the simpler cases of partial convulsion occurring with affections of the optic nerves, with hemiplegia, with disorders of speech, &c., have had particular interest for me. These "complicated" cases are really very much simpler than are cases of "idiopathic epilepsy." Thus it happens that perhaps the most decided of my opinions are to be found expressed in papers, in the heading of which the word "epilepsy" or "epileptiform" does not occur, or in which it is mentioned only incidentally. I will illustrate this—in itself a very small matter—by references to several old papers, in order to show more clearly my manner of investigation, and to give an apology for the peculiar defects of it. Unless this work is a total failure the defects are partly counterbalanced by some advantages. A further reason for these references is that, as my method is unfamiliar, and as probably it may seem to those who have worked at epilepsy under the accepted definition, vague and unreal, the extracts to be given will show that the opinions I have to express have, at any rate, not been formed hastily. On the contrary, there has been a very gradual development, and, of course, change of,

opinion. Many expressions used in the extracts from former papers I should not use now.

In an article on "Loss of Speech" ("Lond. Hosp. Rep.," vol. i., 1864), after stating that we may investigate the relations of affections of Speech to disease of one side of the brain in cases of unilateral convulsions (epileptiform seizures), as well as in cases of unilateral palsy (hemiplegia), I draw attention to the association of right-sided epileptiform seizures (without loss of consciousness) with temporary defect of speech. I then advance the hypothesis that these seizures depend on disease in the same region of the brain (that of the middle cerebral artery), as does permanent loss of speech with right hemiplegia. In other words, the Localisation is in the same region for both sets of symptoms. And I further suggest that the Pathology of these cases of unilateral convulsion is a local change (in the vascular district mentioned), resulting from embolism, as the pathology of cases of loss of speech with hemiplegia often is. In one (to employ more recent terms) the embolic process has led to *destruction* (softening) of nervous matter; in the other, to *instability* of grey matter. (a)

This, indeed, is almost the starting point of my special investigations of Epilepsy. Previously I had accepted what was then, and is still, the almost universal opinion that there is a grouping of symptoms presented paroxysmally, to be called Epilepsy, or "Idiopathic Epilepsy," and that the morbid changes causing this Clinical Entity are in the medulla oblongata. But it occurred to me to study those simpler cases of convulsion (regardless whether they satisfied the definition of "true epilepsy" or not) which begin in, and chiefly affect, *one* side of the body, and to study them in comparison and contrast with a unilateral paralytic symptom (the common form of hemiplegia), which was *known* to be owing to disease of the corpus striatum. This comparison was made in a paper in the *Lancet*, Feb. 16, and March 9, 1867—"Note on the Comparison and Contrast of Regional Palsy and Spasm."

A case of paralysis of the face, arm, and leg, with turning of the head and two eyes from the side on which the limbs were paralysed, is compared with a case in which the face, arm, and leg were convulsed, and the head and two eyes drawn to the side convulsed; in the former there was disease of the corpus striatum (the thalamus was a little involved, too), and in the latter there was disease of convolutions near to the corpus striatum. One was supposed to be Corpus Striatum Paralysis, the other Corpus Striatum Convulsion. Hence, not only the conclusion that unilateral convulsions are owing to disease of one side of the brain, but that they are owing to disease of the brain in a particular vascular region (the region of the middle cerebral artery).

I ought here very prominently to acknowledge my great obligations to Dr. Broadbent's now well-known hypothesis as to the mode of connection of the bilaterally acting muscles with the corpora striata, by which he explains the escape of these muscles in hemiplegia. This hypothesis was of vast importance to me in working out the relations of hemiplegia to convulsions beginning unilaterally. In

(a) The following quotation may be given from the article mentioned in the text. I would remark before I give it that at the time I wrote I believed unilateral convulsion to be owing to discharge of the corpus striatum, and that the disease which led to that discharge lay in some part of the district of the middle cerebral artery, and I believed too the immediate cause of the discharge of the corpus striatum to be spasm of the arteries supplying that centre.

"We may investigate the subject in unilateral convulsion as well as in unilateral paralysis. There is sometimes temporary defect of speech with hemiplegic epilepsy, just as there is permanent defect of the faculty with decided hemiplegia. Now, I do not assert that epilepsy is due to disease of the middle cerebral artery, or of the pia-mater in the range of that vessel—its vascular expansion—but I submit that one particular form of epilepsy is. Perhaps a better expression would be epileptiform convulsion."—"Loss of Speech: its Association with Valvular Disease of the Heart, and with Hemiplegia on the Right Side—Defects of Smell—Defects of Speech in Chorea—Arterial Regions in Epilepsy,"—*London Hospital Reports*, vol. i., 1864.

the paper referred to it was pointed out that Broadbent's hypothesis accounts not only for the escape of the bilaterally acting muscles in hemiplegia, but for their involvement in hemi-spasm. Broadbent's hypothesis is confirmed by Ferrier's researches.

Although the method just illustrated seems simple to me, I find it very difficult to convince other persons that it is simple. In spite of my reiterations that I am seeking the particular cerebral centres discharged in cases where any kind of grouping of symptoms is presented paroxysmally, I find that I often give the impression that I am working only to find the seat of but one grouping, viz., "epilepsy," as authorities define that disease,—that I am working only to find the seat of a disease in which there occurs paroxysmally loss or trouble of consciousness, with or without convulsion. A quotation from a more recent paper will show that my object has not been so limited ("St. Andrew's Medical Graduates' Reports," vol. iii., 1870). After speaking of a case supposed to be carefully investigated on its own merits, I remark: "We do not care to say that a tumour of the brain (or minute changes near it) had 'caused epilepsy,' but that changes in a particular region of the nervous system—say in the region of the left middle cerebral artery—led to convulsions in which the spasm began in the right hand, spread to the arm, attacked next the face, then the leg, &c."

Dr. Eugène Dupuy, in his interesting monograph entitled "Examen de Quelques Points de la Physiologie du Cerveau," says: "Before describing our researches apropos of Ferrier's experiments, we will remark that the idea put forward by Wilks, (a) Hughlings Jackson, (b) and others, of localising epilepsy in the cortical layer of the brain is not new. It is to be found in the memoir of Boucher and Cazauvielh (c). It will be shown further on that this theory is unsustainable."

Whether the theory be sustainable or not I do not discuss for the present. I wish to point out that my aim has not been merely to find the seat of "Epilepsy" in the sense in which that term is generally used. At first it was simply to localise the seat of one comparatively simple set of symptoms presented paroxysmally. It was in 1864 (d) to find the exact results of discharge of parts in a particular region of the brain, regardless whether the paroxysm caused by that discharge was genuinely epileptic or not. More recently, as will be seen, I have used the word Epilepsy as a name for any set of symptoms, sensory or motor, dependent on abrupt and excessive cerebral discharges (paroxysmal discharges). The symptoms

(a) Wilks, "Guy's Hospital Reports," 1866, p. 225, vol. xii., 3rd series.

I will here quote part of what Dr. Wilks has written on the subject, to which Dr. Dupuy refers. I requote it from my article on Convulsion, "Reynolds's System of Medicine," vol. ii., 2nd edition. Wilks says ("Pathology of Nervous Diseases," "Guy's Hospital Reports," 1866) that "the morbid conditions which we find to give rise to epileptiform convulsions are remarkably uniform. They all point to the presence of local irritation of the surface [of the brain]." Speaking of a case of epileptic convulsions in a patient who had tumour in the pons varolii—a case which had been supposed to confirm Schröder van der Kolk's "supposition that the cause of epilepsy is seated in this part"—he says: "I have no hesitation in saying that for one such case fifty might be found in which the marked changes producing these symptoms occupy the surface [of the brain]."

(b) Hughlings Jackson, "West Riding Lunatic Asylum Medical Reports," vol. iii., p. 315, and "Reynolds's System of Medicine," article "Convulsion."

(c) Boucher et Cazauvielh, "Archives de Médecine," Paris, 1825.

(d) It would be only an exaggeration to say that at one time (1864 and some while after) I *did not care* about the seat of the lesion in cases of "genuine epilepsy." Writing about three years later (1867) in the paper on "Regional Palsy and Spasm," referred to in the text, I said: "But I fear *genuine epilepsy* is at present an *insoluble problem*. I would begin, as I have suggested, with a simpler kind of convulsion. I would try to find what condition of nervous matter in one part [of the nervous centres] permitted occasional spasm of the muscles which that part empowers; and I choose the corpus striatum, as we do know, from its frequent damage in hemiplegia, what muscular regions it governs."

usually grouped under the name "Epilepsy" constitute one, but only one, of many groupings of symptoms which I hope we shall be able to localise in different parts of the "cortical layer" of the brain.

The great object I have had in view, as the extracts show, has been to study the relations of epilepsy or epileptiform seizures to simpler diseases of the nervous system, and *through the latter to normal states*. For example, returning to an old illustration, paralysis of the face, arm, and leg (hemiplegia) points to destruction of or of part of the corpus striatum, and my inference is that mobile conditions of the face, arm, and leg (an epileptiform seizure in which these parts are convulsed, or irregular movements of them as in hemichorea), are owing to nervous discharges in the very same cerebral region—discharges of convolutions *near to* the corpus striatum. This is really the study of cases as *departures from healthy states*. For hemiplegia may, for this purpose, be properly regarded as an experiment made by disease revealing to us the external parts represented in the healthy corpus striatum. It shows that the corpus striatum contains nervous processes for the movements of the face, arm, and leg. The unilateral convulsion and the hemichorea are over-developments of such movements which are lost in the quasi-experiment of hemiplegia.

This is just the opposite of the ordinary method of investigating epilepsy and epileptiform seizures. The question commonly put about a case is solely "Is it a case of epilepsy?" or "Is it only an epileptiform seizure?" In other words, cases are often investigated solely in order to see if the symptoms reach or approach certain Clinical Entities, and not at all as they are signs of *departure from health*.

I may here quote again from an old paper already referred to ("Roy. Lond. Ophth. Hosp. Reports," 1866):—

"We want positive information as to how a convulsion is a *departure* from health of muscles and muscular groups (a) and health of nervous organs and tissues, and not as to how far it *approaches* our idea of the almost metaphysical conception 'genuine' Epilepsy. . . . There are to be found on record scarcely any positive statements of what has really happened in particular convulsive paroxysms—a process which sometimes occurs under our very eyes. I am fully aware that there are admirable accounts of the worst fits as types, but some of these accounts are descriptions more of dramas of great human interest than calm and cold scientific observations in an orderly sequence of the outward phenomena of an inwardly suffering nervous system."

I have more to quote to the same effect regarding the localisation of one simple set of symptoms presented paroxysmally as an illustration of my method. In an article on "Defects of Sight" "Roy. Lond. Ophth. Hosp. Reports," vol. v., pt. 4, 1866, I found myself constantly obliged to speak of the investigations of Chronic Convulsive (Epileptiform) Seizures. For example, p. 268, when speaking of cases of Optic Neuritis, complicated with Convulsions, beginning unilaterally, I urge the study of these mobile muscular disorders, regardless of the vested rights of clinical entities.

"Such a kind of work will be more hopeful than working at cases of amaurosis, as they are 'complicated' by the entities 'Epilepsy,' 'Paralysis,' or 'Chorea.' There are, very fortunately, cases in which the symptoms of unilateral muscular disorder refuse to be classed as either unilateral epileptiform seizures, or unilateral paralysis, or unilateral chorea. These cases are, I hold, of extreme value in leading to an organisation of our knowledge of altered physiological conditions higher than an arrangement of symptoms in groups, as epilepsy, chorea, &c.

(a) As will be seen in a later Chapter (on Classification), I do not now object to Clinical Entities for practical purposes. I now admit that they are absolutely necessary. But I object just as strongly as ever I did to the claims of those investigations to be considered Scientific whose aim is only to determine whether a case be or resemble one of "genuine epilepsy." Such investigations are very valuable, but they are Empirical only.

Ophthalmologists will be the last to purposely put amaurosis in association with the abstractions we call 'genuine epilepsy,' 'real chorea,' &c., when it is at all possible to avoid doing so."

As further references to past and scattered work on my subject, I may mention that in the article in the "Ophth. Hosp. Rep.," already quoted from vol. v., pt. 4, 1866, the occurrence of temporary coloured vision, and of other temporary defects of sight in association with unilateral convulsion is considered. In another article (vol. vi., pt. 1, April 2nd, 1868) is an expression of an opinion on that temporary loss of sight which I now call Epileptiform Amaurosis, and used to call Epilepsy of the Retina. (a)

A recent writer, after giving a very brief account of some of my opinions on epilepsies, concludes by saying that most physicians would not admit that the cases I speak of are really cases of epilepsy, because there is in many of them no loss nor trouble of consciousness. If he had said that I was not justified in using the word epilepsy in a new sense I could not have objected to his criticism as criticism. I repeat that epilepsy, as authorities define it, is but *one* of the grouping of symptoms which I believe to result from nervous discharges of parts of the cerebral hemisphere. It is but one of the group which I call epilepsies. Whether consciousness be lost or not, or whether it be lost early or late in an epilepsy, as I define epilepsy, depends on the seat of the "discharging lesion." Cases in which loss of consciousness is the first symptom are cases in which discharge *begins* in the highest centres (in the anatomical substrata of consciousness).

(To be continued.)

## THE INFLUENCE OF SOCIAL AND SANITARY CONDITIONS ON RELIGION. (b)

By HENRY W. ACLAND, M.D. Oxon., M.D. Dub.

Regius Professor of Medicine in the University of Oxford, President of the Medical Council.

FROM the wide subject before you, three points only will be selected for consideration—the basis and aims of sanitary science; the national application of sanitary science; and the share which ministers of religion can take therein. Whatever hypothesis social or sanitary science may advance as to the relations and conditions of man as part of the universe, science can never alter the principles, be they called human or be they divine, on which Christian practice is founded, the principles of universal justice and love. These principles demand in their very nature that by every means and in every direction science should, without ceasing, seek further to alleviate the mental and physical suffering which, by inexorable law, oppresses all conscious life on the earth, and has, as far as we know, oppressed it from unmeasured and perhaps immeasurable time. Science has this in common with religion, that it seeks more to know than to explain. It is ever learning what are the laws which constitute what we call "Nature," in this vast system of conservation, of change, and of dissolution. It admits that almost every individual, animate or inanimate, exists by the destruction or alteration of some other individual entities; and as regards man, science is engaged, among other tasks, in the effort to discover how to guide those vast physical forces which surround him, and how to help him to observe rules by which his physical and his moral welfare may be most fully secured. But, after all, man feels still, as ever, his feebleness. Who now, more than

(a) In passing, I would remark that those cases of migraine with temporary hemipia and other visual troubles (recently well described by Latham and Liveing) are the most important cases of this class.

(b) An Address delivered at the Brighton Congress, Friday, October 9, 1874.

in the infancy of our race, can watch the fury of the elements as they dash on an iron-bound coast; look abroad on the immensity of space, as men looked out of old in the days of superstition and ignorance, on the starry night; weigh the significance of the instincts and habits, the sagacity, affections, and passions of the brute creation, and then say that modern knowledge, astounding though it be, has yet solved the mystery of our state, or has shown man's independence of the general order of the world about him? Will he not say now, as ever, both that the physical and sanitary conditions which surround us must *eternâ lege*, whether we can read them or no, have a definite relation to our moral nature—and also that, in some sense understood or not understood, “not a sparrow falls to the ground but is known to our Heavenly Father”—falls in obedience to laws fixed from the beginning; all form, all matter changing—law alone abiding for ever. To consider, therefore, social and sanitary conditions in relation to religion is practically to affirm that we believe the unity of the laws and arrangements under which man, conscious and responsible man, lives on earth. All who hold this belief can but wonder that men of power, contemplating the phenomena of human existence, should ever dissociate material from mental science—should seek to depreciate the marvel, and despise the requirements of our bodily frames, which, after all said, are the temples, foul or fair, of the spirit dwelling within them. Such and kindred thoughts seem to me to lie at the foundation of the thesis you have proposed for your discussion to-day. Of that thesis the “social” portion must be set aside, to give our few minutes to questions immediately bearing on the relations of health and religion. Habitual intemperance, habitual uncleanness, unchastity, unhealthy dwellings, inadequate food, luxury—all that depresses, all that pampers the body, all that enfeebles the harmonious action of the mental faculties, has to be opposed equally by the physician and the moralist. If it is become a truism to say that vicious, self-indulgent men, however they became what they are, are less capable of physical and intellectual exertion, and of moral or religious exertion, and of moral or religious excellence than they would have been had they lived in virtuous habits of self-restraint, or in refined habits without enervating ease; so also it is not less a truism that preventible material conditions lead to states of the nervous system which promote intemperance and other vices, from which persons living in the open air and in active exercise, though otherwise in a state of want, are nearly exempt. Without further argument, then, this may be assumed, that ministers of religion, as such, and for their special functions, are interested in the physical health of their flocks. The question, it is to be presumed, to be considered by this Congress is rather how far ministers can, with prudence, share directly in the measures which have to be publicly taken for the public health; or how far the division of labour necessarily incident to “civilisation” requires that the clergy in general should be less rather than more occupied with the temporal condition of the people, leaving all measures for the prevention, as well as the cure of disease, strictly to the profession of medicine. I believe that this necessary law of “division of labour” should not here be trenchantly applied. It is a question of time and place, of degree and discretion rather than of kind. There are vast districts in Scotland and Ireland, in India and the colonies, in which it would be simply idle to expect that the medical officers can wisely dispense with the intelligent support of any good and educated minister of religion willing and able to aid them. Now national health and sanitation are terms on the lips of everyone. Sound national health has been said to be that physical condition of a nation which enables the individuals composing it to discharge rightly their respective functions in the state. The statesman, for instance, ought to be in training for the intellectual and social work of his high office; the artisan, the soldier, the abstract thinker, each for his. Sanitation is the attempt to influence for good, by all known methods, the factors which bear on the national health; to promote education

in its truest sense, physical, intellectual, moral; to teach men wisely to work and wisely to play; to make noxious occupations as harmless as they can be made; to hinder men from overtly or secretly poisoning for their own advantage their neighbours' dwellings, air, food, or drink; to show how one form of power or skill, mental or bodily, may be developed without detriment to the higher or general faculties of the man; to endeavour to abolish not only things hurtful, but to limit the abuse of things harmless, or even of things beneficial when moderately employed. Three illustrations out of many will at once occur to you—(1) excessive hours of labour; (2) abuse of alcoholic liquors; (3) uncontrolled spread of diseases originating in preventible ways, and spreading by preventible infection. They are all grave questions, not only for the physiologist, but for the moralist and for the patriot. To discover what manner of life in the several classes of man and of woman, what labour, what recreation, what personal habit of body, what education—nay, what alliance in marriages conduce most to that tone of the nervous system, personal or inherited, which shall put the nerve power of each citizen at the best for the discharge of his public or of his private duty, and how far the state should endeavour to regulate these, are truly prime questions for the modern statesmen. Be assured no vicious man, nor drunkard, nor gambler, still more no masses of such men, can be useful or safe citizens in a free state. Vice makes men feeble. Feebleness makes them irritable. Irritability makes them selfish. Some may, I fear, consider that these observations are, in a grave sense, political, rather than, in a practical one, sanitary. But it is not so. The key to sanitary science is to be found in a full apprehension of its entire aims. The day ought now to be past for discussing the necessity of sewers, sewage irrigation, and kindred topics. Men have perished by hecatombs because of the scant knowledge of builders, architects, and town councils. An able physician, and an admirable and cultivated clergyman (well known to many of you) died but the other day from such preventible causes. That no city, no private houses, when saturated with unremoved filth, are healthy, is now as freely admitted as that personal filth, or drink, or vice engender disease. The clergy and public should remember that this elementary knowledge was taught in great detail three thousand years ago to the Israelites, as they passed along the Wadys that wind round the foot of Mount Sinai. This teaching has been too often forgotten by ascetic religionists anxious to mortify the bodies of men, which they ought to have held as soldiers, in discipline for the good fight, not in subjection, as enemies to be trodden down. Two main principles have to be borne in mind in practically dealing with this subject—(1) that the care of personal health depends mainly on the individual; (2) that the care of national health depends mainly on imperial and local administration. It is clear that in both these two categories a body so influential in a nation as the ministers of religion can effect much. Individuals can be taught what conduces to their physical well-being; and a clergy skilled in doing this, through the schools, the pulpit, and by personal influence, can, in our country, largely aid the intelligent efforts of the members in both Houses of Parliament, and especially, I venture to say, of the House of Peers. That august body contains the heads of the National Church. Whose practical knowledge should better disclose the wants of the denser populations than that of your archbishops and your bishops? Whose voice can better cheer on their way the grave and large-hearted men whose chief pleasure is the welfare of their country, and who feel that they hold their high estate as stewards of her people's good? Who, when natural science is part of a high education, more fitly proclaim the true relations of body and of soul? A few words more on the special relation of these two points to ministers of religion, and my task, however imperfectly, will be fulfilled. A knowledge of how to regulate our personal health as individuals involves a variety of considerations. Abstractly,

knowledge of the structure of the body is desirable for all. Abstractedly, therefore, human physiology should be a necessary subject of early education in schools. But after all said on that head, it is doubtful whether men's instincts, acting with a pure conscience, are not an adequate guide to personal health. The essence of the thing lies in cleanliness, morality, and order. If the instinct of boys, their self-respect, self-restraint, pure conscience, healthy homes, and good mothers are of no avail for good conduct, it is indeed a question whether the knowledge of the constituents of diet, or of the relations of waste to supply in the combustion of the human body will make them temperate in satisfying their natural appetites. But the second subject, that of promotion of national health as a part of national capital, stands on wholly different grounds. With the best possible intentions, and with the highest personal morale, the masses of the population in this country cannot live healthy lives. Reflect, for instance, on the conditions requisite for healthy habitations and the means of providing them in our great towns or our country districts. There are rural districts in these islands where the dwellings have no floors, no chimneys, no privies. There are alleys and streets in our towns where the poor are crowded into rooms without requisite space, or air, or light, or separation of sexes. Now, the poor cannot command capital or soil, or erect adequate dwellings. How are these to be obtained? Are the owners of the soil to be forced by the State to give sites, and the owners of house property to be compelled to give adequate space, or forfeit their property? Who shall decide what is adequate? Where draw the line of State interference with private liberty? In promoting all administrative measures the clergy are, as has been stated, immediately aiding the moral and religious progress of their flocks; and they may be assured that as long as they do not profess technical medical knowledge they are as well qualified by general education as any other citizens, and should be more able than most men to take an enlightened part in local sanitary affairs. They might follow attentively the course of sanitary legislation, read the chief reports which bear on the public health, and assist with their great insight the efforts of their local medical officers, when they are satisfied of their practical utility, for the well-being of all who need their help. Much as this Government has yet to do, recent legislation has made possible all the sanitary machinery that is required for the country. The central authority has power to provide every officer that is needed for its complete work. Every spot in the country can, if it will, obtain competent help. The principles on which sanitary science depends can be discovered only by those whose thoughts are specially occupied in that direction. The full application of those principles demands the education of the engineer, chemist, physician, lawyer, and statistician. But there is still a wide field of work, in which the district visitor, the parish nurse, the minister of religion, all have functions that alone can be discharged by them, as well for the moral as the physical advantage of the people.

### ISLINGTON MORTUARY.

THE new mortuary at Islington consists of two compartments for bodies, a post-mortem room, a coroner's court-room, fitted as the coroner wished with every convenience, and a waiting-room. Nothing could be better for the purpose. During the four months and a half it has been opened, no less than 138 bodies have been received and kept in decent custody until the time of burial, and sixty-six post-mortems have been made. No other words are necessary to prove it was a necessity, and to justify the outlay it involved. The next thing for the authorities to provide is a disinfecting chamber. It is very much wanted, and we are glad to know that the great need of it has been brought under the notice of the vestry by the able medical officer of health.

## A Course of Lectures

ON THE

### NATURE AND TREATMENT OF DEFORMITIES OF THE HUMAN BODY,

DELIVERED IN THE MEATH HOSPITAL, DUBLIN, BY

LAMBERT H. ORMSBY,

Surgeon to the Hospital, and Demonstrator in the School of Surgery, Royal College of Surgeons in Ireland.

#### LECTURE VII. (continued from page 283).

*Treatment of Lateral Curvature of the Spine*, which may be divided into palliative and radical, and as regards the means in use for the above purpose, it may again be divided into the mechanical and non-mechanical. I need hardly say, when lateral curvature of the spine has existed for a lengthened period, and that rotation of the bodies of the vertebræ has taken place, nothing more than a palliative line of treatment can be had recourse to for such a permanent distortion, as it is too far advanced to expect anything approaching a curative result.

When curvature of the spine is detected in an early stage, before any appreciable pathological change has taken place in the position of individual vertebræ, and very slight progress made towards the distortion, a complete change of life would be most desirable, change of air, rest from business, a visit to the country, a tonic line of treatment followed out to combat the weak and debilitated frame, which all through must have been a most likely predisposing cause of the distortion, the person most strongly urged to give up business for a time and do nothing else but attend to the constitution, to rest as much as possible in the lying or semi-recumbent position, and so take the superincumbent weight of the head and shoulders off the spine, as the recumbent position always tends to obliterate the abnormal curve, the erect position always tending to produce it.

Good nourishing food, together with a moderate amount of healthful exercise, cold, or if preferred, tepid shower-baths, to be used freely; also it is sometimes most useful to recommend horse exercise, but to have a side-saddle made for both sides, in order that the person might be able to sit on either side: of course, to be of any advantage, the patient must sit on the side opposite to the lateral projection, and by this means to endeavour to obliterate the deformity. The treatment by placing the patient for a period of ten, fifteen, or twenty minutes, daily increasing the time gradually, on an inclined couch, is most useful, and is the means which have been termed stationary mechanisms, in contra-distinction to the portable appliances so much used in practice. Another plan is placing the patient sitting on the inclined plane, or inclined seat, for a certain time every day, which I recommended so strongly when treating of obliquities of the pelvis. Much can be done in the early and commencing stages of this disease to render permanent and most lasting improvement, and, in fact, in many cases act as a radical cure; whereas, when the distortion has acquired a permanent position, nothing more nor less than a palliative line of treatment can be observed, and, as such, is divided into the *stationary method* and the *locomotive method*, which, by its name, allows the patient to move about, which generally is far more agreeable to the feelings of most persons than to be cooped up in a stationary position. However, cases occur where the people thus affected are unable, through weakness, to move about, and then a stationary appliance is most applicable. The stationary appliance is simply a kind of couch made in a variety of ways and on the most improved principles to suit each person and the existing circumstances of their case, and made by different mechanics, who, as a matter of course, recommend their own make as the very best; and it is in this way that so much one-sided practice has from time to time crept into this branch of orthopædic surgery, and has caused great abuse and diversity of

opinion in the treatment of this important subject; for some will order and apply instruments when they are thoroughly contra-indicated; others, again, are so adverse to such appliances, and will not apply them at all when they are really necessary. Such, I say, is an abuse that any practical surgeon cannot but understand will lead to much irregularity in applying and recommending the use of instruments by those who have but a superficial or limited amount of information in this class of cases. All instruments and methods, I again repeat, have certain advantages, but there is certainly a time to apply and not to apply them. There is a stage applicable to one line of treatment, and there is a stage totally unfit for such treatment; and if authors would, instead of indulging in personal remarks against each other, because their views do not happen to coincide with their own, endeavour to gain from such a diversity of methods sure and certain information to enable them to treat cases in such a way as to render the treatment more definable and less diverse, they would really confer a boon on humanity. There is a time, I believe, when spinal support, no matter how beautifully made and adjusted to fit, will produce more debility than it will improve; instead of giving strength it so hampers the action of muscles that in a short time it produces weakness, and even more debility. Again, I believe the use of spinal supports most admirable, and well calculated to give great relief, and they are now made with such care and exhibition of skilled workmanship that they are light, but firm, and so fitted to be worn under the thinnest dress, so as to elude all suspicion that any instrument was applied or worn at all, and so allows the person to move about. Figs. 18, 19, and 20 are all a variety of mechanical supports applied in permanent lateral spinal distortion; as can be seen, they are all made on the same principle—viz., the pelvis is made the basis of support. Figs. 18 and 19 are depicted applied to the body, but for different sides; Fig. 20 is depicted removed from the body, in order to show more clearly the way it is arranged in front.

FIG. 18.

Appliance for Lateral Curvature of the Left Side.

FIG. 19.

Appliance for Lateral Curvature of the Right Side.

FIG. 20.

A Spinal Support unapplied to the Body.

POTT'S ANGULAR CURVATURE OF THE SPINE.  
This is a very common spinal curvature in scrofulous

subjects, and in the advanced stages, and frequently leads to most unsightly deformity.

*Definition and Anatomical Characteristics.*—It consists virtually in various disease affecting the anterior portion of the bodies and intervertebral substances of one or more vertebrae. The disease may for some time appear dormant and obscure, but after a time well-marked palpable signs begin to show themselves and demonstrate that disease of the vertebrae is slowly but surely commencing. It may affect any portion of the spinal column, but is generally confined to the dorsal and lower portion of the cervical regions; it occurs at any age, but in the majority of cases it commences primarily before puberty, and seldom after. The change that occurs in most cases is as follows: A slow form of subacute inflammation goes on in the anterior portion of the body of some vertebrae and contiguous intervertebral substances; the bodies are softened, and break down anteriorly, causing the spines to divaricate posteriorly, and in so doing produce the angularity. This disease may advance, and when it has reached a considerable extent it may suddenly cease; bony fusion of the bodies takes place, all irritation ceases, and a spontaneous cure takes place, as regards the irritation and inflammation, leaving the person the subject of a most unsightly curvature for life. Take, for example, a delicate scrofulous child that is the subject of this deformity, and the following history will be generally given by the parents or friends: The child from birth has been delicate, having the well-marked signs of the scrofulous diathesis depicted in its face, together with the appearance and constitution; the child is rather tall for its age; complained of pain in its back after the slightest exertion, and most particularly when it sat down suddenly in a chair; the child suffered from constipated bowels, and occasional spasmodic twitchings in the legs. If the disease occurs later on in life, there is a constant, dull, heavy pain experienced in the region that is the centre of irritation. The digestion will be bad, loss of appetite, emaciation, the recurrence of an abscess in close proximity to the situation affected; if the cervical region, a deposition of matter in the posterior pharyngeal region; if the dorsal, the matter may point in the lumbar region; if the upper lumbar region is affected, we have a psoas abscess pointing beneath Poupart's ligament, and many a time an abscess in this situation is the only symptom present that indicates there is irritation going on in the loins—and in the dorsal and upper lumbar vertebrae—opposite to the origin of the muscle. Again, the doubtful consistence of a tumour in the same situation has been cleared up by turning the patient on the face and examining the contour of the spine. Sometimes, I may mention, this examination gives little or no information, as no change can be observed at first in the spine externally, although great pathological change has taken place internally; and the only reason I can give for this is that the patient, when a psoas abscess is discovered, is sent into hospital and kept in the recumbent position, and thereby prevents a likelihood of the cause becoming apparent; but allow the patient to walk about, and you will very soon see the curvature: this is the only way I can account for an immense psoas abscess ending fatally by exhaustion and hectic without any perceptible angular curvature being produced, simply because the patient is kept in the recumbent position during the whole time of treatment. I had a case a short time ago of a young girl, æt. 19, who suffered from a psoas abscess for a very long time before symptoms of curvature were apparent, although she always complained of a dull, heavy, boring pain in her back, corresponding to the origin of the psoas. A very good plan of detecting the irritation is by laying the patient on the face and tapping smartly the spines of each vertebrae, and when the diseased one is tapped the patient will wince. Getting a hot sponge and passing it down the spine will lead to similar results.

When much deformity has taken place by the projection of the spinous processes backwards, the rest of the body begins to partake of a secondary kind of deformity,

and the thorax, ribs, and sternum are very much distorted, and respiration is considerably interrupted. Great tightness of the chest and palpitation are frequently complained of. It is a curious fact, and has been mentioned by other surgeons, that this disease turns out more satisfactorily among the very poor, who are subject to all kinds of depressing circumstances—such as want of attention, misery, and general privation—than among those who have every comfort, and live in comparative luxury; in these this disease general ends unfavourably, by exhaustion, hectic, and other debilitating causes; whereas, in the very poor, without care, attention, or any kind of treatment, the disease ends in a spontaneous cure—that is, by ankylosis and angular deformity, and as such, may live in the same state to a very advanced period of life, and can move about and follow their trade or calling nearly as well as before. Hence we see many examples of the kind walking about in the street, all having a dwarf-like-looking appearance and diminutive in size, for on the recurrence of the disease development no longer increases in an upward direction. If the disease does not end in such a favourable manner, paralysis frequently sets in, and the upper extremities may be completely affected if the disease commences above or in the vicinity of the origin of the brachial plexus of nerves; if in the dorsal region, complete paralysis of the lower extremities, with all the other usual concomitant symptoms, such as bed-sores and inability to pass water, &c.; all these symptoms increase, the patient goes on from bad to worse, and death relieves the unhappy sufferer; or it may occur suddenly by the bursting of a large psoas or lumbar abscess, or the falling in of two or three vertebrae, so crushing and compressing the spinal cord.

*Treatment.*—Like other curvatures, much can be done in the early symptoms of the disease. Rest in the horizontal position is the plan which all agree to be the best before any perceptible curvature has arisen, good strong nourishment given, cod-liver oil, the preparations of iron, some of the preparations of lime, XX porter, in the second stage when there is well-marked symptoms of irritation, caustic issues about the size of a shilling to be made on each side of the spine, and followed up by a good strong line of constitutional treatment; leeches have also been placed over the seat of pain. But I cannot say much for the treatment with rest, good diet, and a favourable posture of body; ankylosis is the point arrived at, which, when attained, is nearly all the surgeon can do to effect a cure. A mechanical spinal support, made on the same principle as the others mentioned, but with a slight modification, having a padded plate made to fit on the convex projection, gives general support, and also taking the superincumbent weight of the spine.

In concluding my remarks on this subject, I ought to mention there is a plan of treatment or a line of practice called the "spinal gymnastic treatment"—a plan that is also supposed to effect in itself wonderful and complete cures. Now, I am obliged to say I don't believe it, much as I approve of gentle gymnastic exercise, and frequently recommend it as being most valuable in the treatment of some cases. I do strongly disapprove of plans that string people up in a most ridiculous manner and suspend them by the back for the purpose of straightening the spine. All I can say is, that in any cases I have seen, such a line of practice would produce most injurious results, and we must only go back to three or four hundred years to look for such unscientific treatment, and also read the results, for, if it did not produce greater deformity than it was supposed to rectify, it left the patient very much in the same position as before, disappointed and worn out by such methods as I have described.

Another point I should also mention about spinal disease and deformity: There are a number of hysterical young ladies, or would-be "invalids" who frequently complain of their spine, and say they have spinal curvature, and, as a plea, remain in bed. I have had a number

of such cases under my care, and I must say they are most difficult to treat, as you will find, for it is not the slightest use "to argue the would-be patient out their belief." At the same time you know that no disease exists. I had one case under observation of a lady who was for 36 years bed-ridden, and under no pretence whatever would she be persuaded to get out of bed. However, she got an attack of bronchitis, caused by an open window, which ended in her death, and permission was given me to examine her spine, and not the slightest disease or distortion existed; and it seemed this lady got to like her bed so much that she would never even try to get up, and so persuaded her friends she had spinal affection that they never even doubted the fact until I informed them that they were all mistaken.

#### SPINA BIFIDA (OR HYDRO-RACHITIS).

This is a congenital spinal affection, which is the only one, I may say, that exists at the time of birth; it produces great deformity, nearly always ends fatally, and treatment does very little good, and, if attempted frequently, accelerates a fatal result.

*Anatomical and Pathological Characteristics.*—It occurs in very early foetal life; it consists in an arrest of development or coalescence of the laminae and spines of the vertebrae, they do not unite, but remain separate, and appear double, hence its name *bifida*; or in some cases the neural arch is not developed at all; the membranes of the cord, containing the cord and spinal fluid, bulge out at the opening, and produce a tumour varying from the size of an egg to that of an adult head. Treatment, as I mentioned, does not do very much for it. You will ask me, How does it terminate? Well, you are spared the trouble of much treatment in many cases, for it bursts at the time of birth; or it may increase to an enormous size and then burst; or its summit may ulcerate, and thus produce a similar ending; or the pressure of the subarachnoid fluid on the terminal twigs of the nerves may produce convulsions and death.

The treatment recommended is as follows:—

1st. *Pressure.*—When the tumour is very small, firm pressure, evenly applied with thin metal plate, gutta-percha, or india-rubber.

2nd. *Puncturing* the tumour with a trocar and canula, or, as is now used the "aspirator."

3rd. *Injecting* with very weak solutions of iodine, as mentioned by Mr. Holmes.

4th. *Excision* of the tumour when it is very small has been practised, and, in the case recorded, success is said to have followed, the neck of the tumour being first closed by a clamp before the operation.

Mr. Bryant, in his "Surgery," mentions this as the best treatment for such cases.

(To be continued.)

#### PHASES OF CEREBRAL DERANGEMENT.

By Surgeon-Major F. R. Hogg, M.D.,

Fellow of the Royal Medical and Chirurgical and other Societies.

In the traditions of the past we read that, through poverty, sickness, mental excitement, nervous mimicry, during damp depressing weather, inundations, political crises, religious superstition, the minds of many weakly, solitary, sedentary, idle, frivolous, or those engaged in unhealthy trades or occupations became unhinged, specially in June, about the festival of St. John, the attacks, however, noticed in summer or winter, the air moist or dry. Debilitated by hunger or bad food, influenced by imagination, well or ill-health, tailors, shoemakers, mechanics, farm labourers, clergymen, decrepit grandfathers, young girls, all formed circles to dance frantically together in wild delirium through towns and villages until they dropped of sheer fatigue, or were relieved by abdominal bandaging, by friendly blows or kicks in the stomach, to

dispel flatulent tympany. Beautiful young ladies, demure nuns, frisky matrons, dashed their brains against walls, sobbing, laughing, crying, stripping off their clothes, standing on their heads, mewing or barking like cats and dogs, and averse to pointed shoes, red clothes, or persons weeping, these maniacs, fiercely loving music, looking-glasses or bright metals, eagerly longed for the sea; some imagined themselves bitten by spiders, inspired by angels, possessed by devils.

In heated workshops, in crowded sensational churches or chapels, both sexes would fall into epileptiform convulsions, rocking their bodies backwards and forwards, sawing their arms, the legs occasionally remaining quiet, some wriggling themselves after the manner of fish suddenly cast on dry land. Abdominal cramp, flatulence, constipation, diarrhoea, dysmenorrhoea, dysuria, depression, dirty tongue, quick irregular pulse, aphasia, insomnia, insensibility to external impressions, tonic spasms, preceded by languor or sleep, persistent tremor, vomiting, sobbing respiration, permanent fatuity—such were the varied symptoms, relieved by beating the feet or extremities with hammers or clubs, by drenching the patient with cold water, by galvanism, or the administration of opium. During the attacks other nervous symptoms for a while would subside, and pregnancy both as regards mother and child be uninfluenced. Mayo, however, states that a woman in the fourth month of gestation had a frightful object thrown at her bosom, inducing nervous fever, and at the full period the child, previously preternaturally lively *in utero*, emerged into the world a choreic girl, who, at thirty years of age, continued the movements, her mind almost idiotic.

Hecker, or rather Cooke, tells us of the shepherd boy who started the child crusade of 30,000, all bound for Jerusalem, to reconquer the Holy Land, sons of rich and poor, girls in boys' clothing, and to the grief and despair of parents. Seven ships full sailed from Marseilles; two struck on a rock—not a soul saved; the remaining five ship loads were sold as slaves to the Saracens. A second pilgrimage of 7,000 fared no better; many died of debility or starvation in Alpine passes; those who returned were jeered at or bound by the Pope to undertake the conquest of Jerusalem in after-life. My experience of chorea in childhood, after marriage (*vide* MEDICAL PRESS), during pregnancy, has taught nothing beyond the symptoms, the association with rheumatism, anæmia, or endocarditis. The high specific gravity of the urine, the frequent absence of organic change, the cerebral lesions, or the increased vascularity in the central ganglia, the warty vegetations sometimes noticed about the mitral valves, are by no means specially diagnostic. Although cases are tedious and singularly distressing when isolation cannot be maintained, the treatment only involves time, confidence, and common sense, excepting during pregnancy, when death or paralysis may result to mother or child. My impression is that dengue during pregnancy may occasion infantile chorea. Considering the sun, the rains, rheumatism, thunder, intense heat, extreme cold in India, it is very puzzling to find that during ten years in Bengal but 5 women, 6 children, and 29 men suffered from chorea—not a single death, the year 1868 affording most instances, when four men were invalidated. Cases of malingering are not common, such as spinal disease or paralysis; nor are phantom tumours, nor the curious mimicry of abdominal or other aneurisms often met with amongst soldiers' wives.

Acupuncture, galvanism, chloroform, as suggested by Sir J. Paget, clear such doubts. Dr. Hughlings Jackson also states that in real hemiplegia the paralysed arm falls forward when the patient stoops; when feigning the arm will be retained by the side. In genuine cases, chained to bed, the muscles waste, and the soles of the feet become cracked and scaly. We know that epidemics seize the joyless, the depressed, the timidly nervous; no statistics can tell how many have died of simple fright. Drunkards have been known nervously to feign hydrophobia, like dogs or committing outrageous excesses.

to detection. Beyond structural changes connected with the medulla oblongata, the pneumogastric and spinal accessory nerves, but little is known of this disease, which from 1860 to 1869 occasioned 21 deaths in Bengal. From the limited experience of one case my treatment would include Turkish baths, or the hypodermic injection of chloral into the back of the neck. Writers' cramp, affecting dissipated musicians, unable to play the violin, was occasionally met with at Woolwich, and relieved by iodide of potassium, strychnine, galvanism, and good living; one interesting case perhaps Dr. Wilks has the notes of. Of 390,678 soldiers in Bengal, from 1860 to 1869, certain admissions into hospital ran as follows: Meningitis 66, myelitis 9, encephalitis 64, sunstroke 1,812, paralysis 639, tetanus 14, delirium tremens 1,750, paralysis agitans 8, neuralgia 1,773, cephalæa and vertigo 3,033, mania 425, dementia 546, melancholia 52; of these the deaths from meningitis were 25, sunstroke 858, paralysis 60, tetanus 8, delirium tremens 187, mania and dementia 17, and so on; invalided were meningitis 5, encephalitis 9, sunstroke 92, paralysis 192, neuralgia 37, vertigo 117, mania 106, dementia 185, melancholia 14. Neuralgia, both in the hills as well as the plains, tortures terribly the incurable.

However, besides heat, damp, climatic conditions, malarial influences, weakly constitutions, the direct and indirect deterioration of body caused by drink, syphilis, excessive smoking, careless living must be considered. Of 1,468 epileptics 22 died, 279 invalided, notably in 1860, a most difficult disability to detect at enlistment, for the eyes, the face, and demeanour are not invariably characteristic of a disease so easily provoked or reintroduced.

Bromides and iodides act very capriciously in hot climates, and unless the patients are officers or ladies, anxious to assist their own cure, the labour is that of Sisyphus. Somnambulists occasionally bring trouble on themselves and others. Suicide and suicidal wounds accounted for 118 deaths; 21 only in hospital the instances of cut throat, hanging, drowning, poisoning by opium, arsenic, prussic acid, cyanide of potassium; by shooting or decapitation, by railway trains, at various times personally noticed or encountered, were invariably associated with drink or women, or both, the most trivial reasons sometimes. After the rains in India great mental depression fastens on us all. By all accounts, at Lucknow, with round shot crashing into houses, shells bursting in the roads and verandahs, bullets whistling ping-ping or thudding against the walls, and mines like earthquakes shaking the very foundations, many children were prematurely born, the strong only surviving. As comrades fell, and week after week drearily dragged on without good news, many, losing heart, suffered from nervous ailments, specially irritation of the bladder; but the love of life continued. Out of 6,650 women in India in 1872 no cases of chorea recorded; paralysis 6, neuralgia 48, hysteria 33, puerperal convulsions 2—no deaths; rheumatism, 1 death out of 120 cases; epilepsy 13 instances—2 deaths. These statistics, of course, can only afford approximate ideas and information. Cerebral diseases of women may depend on anæmia, menorrhagia, uterine hæmorrhage, early marriages, sterility, rapid pregnancies, hyperlactation, domestic troubles, jealousy. Uræmic convulsions and puerperal mania, both dangerous recurrent diseases, may be averted by early diagnosis of patients proclivities. A woman with moon-blindness recently attracted attention. Children in India often run about bare-headed in the blazing sun. Of 11,657 in 1872, meningitis occasioned 37 admissions, 27 deaths; hydrocephalus 20—11; convulsions 225—171; dentition 401—92; sunstroke 11—3; chorea 3 admissions, no deaths. Dr. Bradshaw, Surgeon to the Commander-in-Chief, tells me that the experience of seventeen years in India amply testifies to the value of small doses of morphia to calm the nervous irritability of children during intense heat. Salaam, or nodding convulsions, will be met with in army medical practice, also the frequent fatal diversion of pneumonia, whooping-cough, or eruptive fevers into tubercular meningitis. Of 1,560 officers in 1872 the 26 deaths included but one case each of apoplexy, concussion of the brain, or tetanus. From

1860 to 1869 snake-bites figure in Bryden's tables as 13 admissions—2 deaths, the accepted theory being that the heart is tetanised, the circulation checked, the muscles of respiration paralysed, asphyxia caused, besides septicæmia. Lightning occasioned 3 admissions all fatal. There is a case at Mooltan of progressive paralysis affecting a young fair-haired, married man stunned by lightning. These observations refer entirely to Europeans, for whom endless resources and recreations are annually increasing in India—let me add the finest country in the world in some respects for every poor man provided he be of good constitution, also of active, careful, abstemious habits, and adapting himself to the climate.

Simla, India, Sept. 1st, 1874.

## STRYCHNINE AS AN ANTIDOTE TO OPIUM-POISONING.

By ALEX. G. BURNES, M.B.

THE *Medical Times and Gazette* of September 26th contains an extract from the *New York Medical Journal* for August referring to a case of morphia-poisoning successfully treated by atropia and electricity.

The chief interest of this case lies in the fact that great credit is given to the atropia, for Dr. Trask (the patient in question) says "he believes that the influence of the atropia in mitigating and eventually triumphing over the morphia was evident;" yet, farther on, he says "he is disposed to believe that the great nervous prostration under which he afterwards suffered, and especially the loss of locomotive power in the lower extremities, is to be ascribed to the influence of the atropia;" and, again, he says, "in one case reported by Dr. Schweig the patient was saved by the electric current alone." It is to these three points I would call especial attention. Now, the first point—viz., "the influence of the atropia in mitigating and eventually triumphing over the morphia was evident," is entirely opposed to the views advanced by Dr. Jno. Harley in his work on the "Old Vegetable Neurotics" (page 300), where he states that "atropia increases the cerebral and anæsthetic effects of opium," and "that the influence of belladonna in removing the respiratory difficulty is slight and ineffectual, since it extends only to the release of the bronchial tubes, without affecting the diaphragm or external respiratory muscles." These remarks will also apply to the second point referred to above, and in connection with the third point, the following remarks of Dr. Harley are important and interesting.

1st. That of several cases he examined, the evidence of antagonism (between atropia and opium) in any given case was conclusive.

2nd. Taken individually or collectively, the cases showed that belladonna had no influence whatever in accelerating the recovery from the poisonous effects of opium.

3rd. That somnolency, stupor, narcotism, and coma, the essential effects of opium, are both *intensified* and *prolonged* by the concurrent action of belladonna.

4th. That belladonna is powerless to obviate the chief danger in opium-poisoning—viz., the depression of the respiratory function.

5th. That the results of the combined action of opium and belladonna are the same, whether given in medicinal or toxic doses. While, therefore, belladonna cannot in any sense be regarded as an *antidote* against opium but in large doses, the *exact reverse*, it may, under certain conditions (*vide* page 309), and always in *small* doses, be used in conjunction with other remedies as a means of aiding the recovery.

The above remarks, which I fully agree with, all serve to show that we will not find an antidote in belladonna against opium. It now remains for me to detail a few experiments conducted by Mr. F. J. Mavor, and related in our conjoint work, "The Specific Action of Drugs," to show what is the *real antidote* to opium (page 127).

*Experiment 1.*—Half a grain of acetate of morphia was given by subcutaneous injection to a dog at 4.50 p.m., temperature being 101°, pulse 70.

At 6.50 dog was sleeping, the secretion of saliva greatly increased, and flowing from mouth. When roused it had no power over hind legs. Temperature 99°, pulse 70.

At 7 o'clock 1-23rd of a grain of nitrate of strychnia was administered. Within a few minutes the flow of saliva ceased, the sleepiness passed off, and the dog rose up and walked about; while at 8 o'clock the animal was quite lively, and in its normal condition.

*Experiment 2.*—In this case, half a grain of acetate of morphia was given subcutaneously to a dog at 5 p.m.

At 5.40 the animal seemed drowsy; the secretion of saliva was increased.

At 6.15 animal very sleepy; saliva flowing freely from mouth.

At 6.50 gave 1-16th of a grain of nitrate of strychnia. At 7.5 violent rigidity of muscles; respiration rapid; heart's action very weak.

At 7.20 rigidity subsiding; dog very drowsy.

At 7.30 made several attempts to rise, but failed; the flow of saliva ceased.

At 7.40 succeeded in rising, and was able to run about, but was very nervous, and easily startled.

Next day was quite well.

*Experiment 3.*—In this case one grain of nitrate of strychnia and four grains of acetate of morphia were given by subcutaneous injection to a horse at 11.30 a.m.

At 1.10 muscles somewhat rigid.

At 3.40 rigidity subsided.

Next day, 12 noon, animal in normal condition.

*Experiment 4.*—Some days afterwards, to the same horse was given, by subcutaneous injection, eight grains of acetate of morphia and one grain of nitrate of strychnia.

At 10.45 the only effects produced by this dose were slight dilatation of pupil, and reduction of pulse from 40 to 36.

At 4.30 the animal was in a normal condition, pulse and temperature same as before commencement of experiment.

*Experiment 5.*—In the following experiment one and a quarter grain of nitrate of strychnia was given to the horse at 3.10 p.m.

At 4 p.m. rigidity of the muscles.

At 4.5 p.m. injected subcutaneously ten grains of morphia.

At 4.15 rigidity nearly all passed off; horse rather restless and excited from the morphia.

At 4.30 rigidity and excitement subsiding.

At 7.30 slight increase in secretion of saliva; horse still restless at intervals; but next day all effects passed off.

Such is the results of experiments with strychnia and morphia on the dog and horse, and I have no doubt the effects would be the same on man, and believe that here we have a fully proved *antagonistic* action between these drugs.

About three years ago a correspondent of the *Medical Times and Gazette* contributed a report of several cases of opium poisoning treated by atropia, but as he had in all the cases conjoined other treatment, such as electricity, strong coffee, emetics, &c., he invalidated the importance of his results in a scientific point of view. Now, at that time I called attention to this fact, and also related some of the experiments recorded above, and as yet I have seen nothing to disprove the conclusions I then drew therefrom. I trust others may direct their attention to this important subject and publish the results of their experience.

## SOCIAL SCIENCE CONGRESS.

THE Public Health Section is the one in which our readers will be most interested. It was presided over by Dr. L. Playfair, who delivered a lengthy address ranging over all the subjects usually included under the term Public Health. Our space does not admit of our following him through all these; but we must make room for his exposure of the manner in which our sanitary legislation has been muddled. On this subject the President said:—

“In England, at the present time, there is a casual agglomeration of 1,500 separate sanitary authorities, without system or cohesion. Their areas of administration are diverse in the extreme, being neither bounded by counties, parishes, nor natural watersheds, and their duties are divided without meaning between authorities in the same district. They have been lately put under medical officers of health without preparation or qualifications for their duties, some well paid and devoting their time to this important work, others having little more than nominal payment and giving little more than nominal time to their important duties. Notwithstanding this too sudden and unprepared universal appointment of medical officers, yet in the administration of the Health Acts there has been recently manifested a disposition to ‘distrust the doctors’ and to work the Acts, at least at head quarters, by lawyers and other persons not connected with the medical profession. This is the old error of making common sense the fetish for worship, which Archbishop Whately and others have so effectively condemned. Even the most fervent worshipper of common sense, as opposed to technical training, never relies on it in important emergencies of his life. He goes to the lawyer to make his will or to convey property; he consults the parson on religious doubts when on the sick bed; and he does not spurn the doctor to cure him of his grievous ailment. But it is well known that the Local Government Board are afraid of the doctors in the administration of Health Acts. Who beside them possess the knowledge? I can testify, from an experience of thirty years in sanitary work—and impartially, because I am not in the medical profession—that there is not a class of men in the country who labour so zealously for the prevention of disease as the doctors, though their training hitherto has been cure, not prevention. Certainly their private interests have never been allowed to stand in the way of their efforts to uproot disease, although their living depends upon its existence. This unselfishness in the application of their science to prevention has always been to me a source of high admiration. Why, then, is there this vulgar distrust of the doctors in the administration of our Health Acts? Extend this prejudice against technical knowledge, and how absurd it would be. Would you improve the progress of telegraphy in this country by suppressing electricians; or the law and justice of the country by putting down lawyers? Would the Secretary at War promote the conduct of war by suspecting soldiers; or the First Lord of the Admiralty the efficiency of fleets by distrusting sailors? Would our railroads and harbours be better governed if engineers were held at a discount? But this is actually the state of things at the Local Government Board—the Health Ministry of the country. The Privy Council handed over to that board Dr. Simon and his associates, with a wealth of medical experience in public hygiene. Ever since, that wealth has been locked away from public use. Certain I am that their experience could not have guided the board in the utter confusion of organisation in regard to medical officers of health. They have been appointed without any system. Some have a small parish to attend to, others have a thousand square miles. The last are appointed for combined districts, but are managed by uncombined authorities, and have neither assistants to aid them nor power to enforce their decisions. The officers of health are without any definite rule for obtaining available knowledge of prevailing sickness, even when it is treated at the public expense within their own districts; and they are not, universally at least, informed of the deaths as they occur. The medical officers of health have been appointed without any examination on their knowledge of State Medicine, and in the majority of cases they do not possess this knowledge. I am perfectly certain that this utter confusion could not have resulted had the Local Government Board consulted the experienced State medical officers belonging to them. This distrust of the doctors in higher adminis-

tration is simply a general mistrust of science. And the time has now arrived when science must be trusted in government. Science is entering into the higher education of the country, and the prejudice against it among legislators, who were educated in classical universities, will in time be removed. For the progress of a country depends upon the progress of science, and the welfare of a nation is secured by the most intelligent application of science to its manufactures and to its government. The health of the country—and that governs the productive power of its people—depends as much upon the applications of medical science as the working of a machine depends upon a good application of mechanical laws. To trust the whole administration of Health Acts to Poor-law inspectors and lawyers is an amazing example of unbelief in the first principles of the laws of health. The well-being of the people depends upon physical causes, which, when intelligently understood, mean physical science, and the trained physician is the natural and most intelligent agent for extending its knowledge and application to the prevention of disease.

What we want in the future is not new law, but more efficient administration of existing law. To heap up new sanitary law on the decaying mass of indigested sanitary law which already forms a dismal agglomeration, is like the practice of our ancestors, who thought that a few clean rushes, thrown upon the corrupt mass of foul rushes on the floor, sufficed for sanitary purposes. What we want is superior organisation and efficient administration of existing law. But, in our happy-go-lucky style of government, are we likely to get it? I doubt whether it will be wise to continue the local government as a separate department of the State. Its functions, in reality, appertain to the Home Office, which, when properly organised, should divide itself into two great departments—the one dealing with police and justice, the other with the physical interests of the people. One Secretary of State might have the supreme responsibility, but each of the divisions should be scientifically administered. It would be as absurd to put a man trained in physical science at the head of the branch of police and justice as it is to put a man merely trained in law in charge of the physical interests of the people. It is an exploded fallacy that only lawyers are good men of business, and that scientific men are not. Is my friend Sir John Lubbock a worse banker because he is an eminent man of science? Is Mr. Spottiswoode a worse printer because he has distinguished himself as a physicist? Is Mr. Warren Delarue a worse stationer because he is equally conspicuous as an astronomer and as a chemist? The local government of the country, in as far as it relates to the physical interests of the people, will remain an example of arrested development unless science receives a recognised position in its administration. Now, the Local Government Board is drifting into the position of a large and responsible ministry dealing with the physical interests of only one portion of the people, and having no imperial object or comprehensiveness; for, though it includes England, it excludes both Scotland and Ireland.

Mr. DAVID GIBB read a paper on "The Relative Increase of Wages, of Drunkenness, and of Crime during the last Five Years in the Central Mining Districts of Scotland." Mr. Gibb said the industrial result of the unprecedentedly high rate of wages obtained between 1869 and 1873 had been almost wholly disastrous.

Dr. ALEXANDER ROBERTSON read a paper advocating further legislation for persons labouring under mental disorders resulting from or characterised by excessive indulgence in alcoholic liquors.

Dr. YELLOWLEES, of Gartnavel Asylum, read a paper on "The Criminal Responsibility of the Insane."

Dr. ANDREW FEBGUS, of Glasgow, read a paper on "The Sewage of Towns and Disposal of Organic Refuse." He objected to the water system, and advocated the return of excreta to the earth.

Mr. BALDWIN LATHAM, C.E., read a paper on "The Sewerage of Towns." The object of his paper was to reverse the preceding one—viz., to show the necessity of procuring water in abundance for all our large towns. After the water was procured, it must subserve all the purposes of removing the alvine discharges of the population as well as all the liquid refuse from slaughter-houses and manufactories. The dry system of collecting the alvine discharges had never been shown to be remunerative; the liquid portion of the sewage had also to be dealt with, and it was as difficult to purify that portion as if it contained alvine discharges.

Major-General H. Y. D. SCOTT, C.B., read a paper on "Legislation for the Restraint of River Pollution."

BAILIE MORRISON, Chairman of the Committee of Management of the Glasgow Improvement Trust, contributed a paper on "The High Rate of Mortality in Glasgow, with Observations on the Measures taken by the Municipal Authorities to reduce the same under the 'Glasgow Improvements Act, 1866,' and other Public Acts." The high death-rate in Glasgow was simply from a variety of causes—(1) the character and occupation of the population; (2) the impurity of the atmosphere; (3) density of population and overcrowding; and (4) infant mortality. In Glasgow, 3,085 houses had been demolished by the City Improvement Trustees, displacing an estimated population of 15,425; to provide for which, and the natural growth of the city, 26,974 houses had been erected within the municipal boundaries, from 19th June, 1866, to 31st August, 1874, which were estimated to accommodate 133,970. This did not include the numerous buildings in the immediate outskirts of the city.

The Rev. B. J. SIMPSON also read a paper on the same subject.

Mr. SIMPSON claimed special attention to the following four points in providing dwellings for the labouring poor.—(1) Let them be as convenient, or—to use their own expressive term—"handy" as possible to the work of the people; (2) Let them not be too much congregated into one faubourg or quarter, objectionable alike on social and on political grounds; (3) Let there be, if possible, in the buildings, or hard by, a good wash-house and a "crèche" or "infant nursery," in which to tend and guard the infants during the parent's absence at work, and thus enable the elder children to go to school; and (4) Let there be, if it can at all be secured, a playground or vacant space, where the children can play without the probability of being run over by a butcher's cart or contaminated by the lowest company of the streets.

The Rev. Dr. J. ELDER CUMMING contributed a paper on "The Neglect of Infants in Large Towns, with some Remarks on the Crèche System." He was not an advocate for having a large crèche of fifty or sixty children, but a number of small institutions, taking up district after district. The advantages which could be fairly claimed for the system were:—For the infants themselves, good and suitable food, sufficient warmth, shelter, and ventilation, constant cleanliness and medical care; and for the mothers, the effect had come to be that, accustomed to see their children in a state entirely different from what they had ever known before, they made afterwards an effort to keep them so; and for the public at large, it might be hoped that an extension of the system would gradually lead to a great decrease of infantile mortality, and the rapid and decided improvement in the bodily condition and health of the children who were spared.

Mr. F. FULLER read a paper on "Our Paramount Duty to Provide Wholesome and Pure Recreation and Amusement for the People, and the Dire Results and Dangers which attend Neglect of It."

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 14, 1874.

PROFESSOR HUXLEY'S INTRODUCTORY AT OWEN'S COLLEGE.

PROFESSOR HUXLEY delivered an address at Owen's College, which will be taken as the most striking of the

provincial introductory, just as the opening of the new buildings of the medical department places the Manchester Medical School in so high a position. These new buildings are described by the Manchester papers as worthy of the great capital of Lancashire, and Professor Huxley compared Owen's College with old universities in the most favourable manner. It seems that provision has been made for the efficient teaching of all departments in the most thorough way. The professor of chemistry finds himself in one of the best laboratories in the kingdom—some say in the world. The professor of physics has a laboratory with which few men can compare, and other teachers are equally well provided.

The anatomical theatre is large enough for 250 students; the medical theatre for 150. The dissecting room is 77 feet long and 32 feet wide. Its floor is of asphalt, and it is fitted up in a way said to surpass those of the metropolis. The museum, library, and other rooms are on a similar scale.

From what medical visitors tell us we are not surprised to find that the place drew from Professor Huxley unqualified admiration. He confessed his pride to be in his position on that day, and congratulated Lancashire on having, by its own efforts, accomplished so great a work. He even anticipated that the future would only increase the good work thus nobly begun. It is not unnatural that he should have fastened on the Dalton and Platt Scholarships as particularly commendable. These are prizes for original research; and new as this feature is in education, it is perhaps one of the most important in its bearings on the progress of science. England has few prizes for men of science of any kind. Scholarships open to young men who display ability in original work can scarcely be established without exercising great influence.

Having spoken a friendly word of the arts department, and stimulated the Lancashire lads by a statement of his experience as an examiner, the Professor addressed the lay portion of his audience in his usual happy way, and showed them by a familiar illustration the necessity of so complete a school of medicine.

If we cannot admit that his analogy holds good throughout, we find it sufficiently interesting to give an outline of it.

The Professor supposed that his hearers might be puzzled to know why so elaborate an apparatus is needed for the teaching of medicine, and why men require to spend so long a period of arduous study in that most important of pursuits; and he suggested that this surprise arises from the prevalence in the general mind of the notion which was once exceedingly common in the philosophical mind—that the human body in general is dependent upon forces and powers which were altogether different from those we find working in other kinds of matter. He went on to add that it is not two hundred years since the notion existed that the vital processes of the body were subject to some demon who kept the body straight when in good temper, and let it go wrong when out of sorts; and, when it was gravely supposed that there was a broad gulf between the phenomena of inorganic nature and those of life. Difficult as he would find it to prove this to be a fair statement, we admit as much more just the opposite that the whole of our modern

scientific study of medicine depends upon precisely the contrary assumption—upon the assumption that the living body is a mechanism infinitely more refined, and infinitely more difficult to understand, than our coarse human machinery; but still the mechanism of it is governed by rules and laws which can be discovered, and which can be applied and reasoned from, in order to understand its processes.

"Modern medicine, in fact, is a kind of engineering," said Prof. Huxley: "It is the attempt to understand the machinery of the body, for the purpose of being able to put it right when it goes wrong. I have seen in your great factories in Manchester some of those astonishing complicated pieces of machinery which seem almost endowed with life, by which the products which make Manchester so famous are produced. Let me put before you the case of the possessor of one of those machines, who, finding that it has gone wrong and that it will not work properly, finds himself, as Sir Robert Peel would say, with three courses open to him: either that he might sit down and hope that it would get better, and, perhaps, even offer up his prayers that it might get better; or that he should send to the nearest blacksmith and tell him to bring his hammer and bottle of oil, and tap here, or oil there, in the chance of setting the machine right; or should, thirdly, send for some skilled and experienced mechanic who, from long study and familiarity with it, would be able to judge by the mode of action where it was wrong, and be able to put his finger on the part which was broken or injured, and thus be able to set it right. Now the human body is a machinery which, in complexity, stands to the spinning-jenny in the same relation as the spinning-jenny stands to a child's windmill. But it stands by the same laws, and those who have to deal with it must be guided by the same reasoning. Sickness is the going wrong of the machinery. Death is the destruction of part of the machinery; and the only way in which that machinery can be set right if it go wrong, is not by sitting down and hoping for it is not by sending for the first blacksmith, who will administer his purge here and his bleeding there, and who is what we call a "quack;" I mean a person who is really ignorant of that with which he is dealing, and who yet, nevertheless, presumes to meddle with it. That is the essence of quackery. Or, thirdly, we must send our skilled engineer, who, by the help of what he calls symptoms, finds out what wheel is out of place, what cog is broken, and by his previous knowledge of therapeutics and remedies, knows in what way it is possible to get this erring wheel or broken pinion into its place again. And it is in order that we may have such skilled engineers to the body that all this great apparatus, which you see erected here, and all this long period of study is carried out."

Having shown the need of good preliminary education and of much severe study, Prof. Huxley turned to the new students and said in conclusion:—

"You have before you probably that which is the most responsible of all human careers. It is hard for you not to realise that. It is hard for you, curbing the hot blood of youth, to understand what issues may depend upon your present career; but depend upon it, exactly in proportion as you make use of these advantages, as you feel the burden of your responsibilities, as you acquire that knowledge which was essential for you, so will your lives in the future be passed in the satisfaction of well-merited renown or in the misery of a violated conscience."

#### THE INFLUENCE OF CONTRACT DOCTORING ON THE EXPECTATION OF LIFE.

THE great danger not only to the profession, but to the public, to which we have more than once called attention in referring to the system of club, or contract doctoring,

which is now much belauded, is dealt with in a new line of argument by Dr. Tweeddale in the number of the *Melbourne Medical and Surgical Review* for last August. We have from time to time urged upon our readers the consideration, that by lending their countenance to "provident" dispensaries and pseudo-charitable institutions, they incur the peril of including within the boundaries of these so-called charities a vast number of well-to-do mean people, who will never pay a sufficient fee for an attentive consideration of their case as long as they can defraud the doctor into the expression of a slap-dash dispensary opinion, the writing of a hasty prescription, and the giving of a cheap and useless PLACEBO of medicine. We don't look at the sixpenny dispensary or the threepence-a-head sick club solely from the point of view of its influence on the profession, although our readers may well take to heart the ultimate result of encouraging a low class practitioner to attend people of any rank without restriction for a nominal fee.

We regard it as thoroughly short-sighted to invite the artisan class (even supposing contract doctoring to be restricted to them) to level themselves to the condition of medical paupers, and to content themselves with such medical advice and physic as they inevitably receive for a sixpenny fee, or a threepence-a-year subscription. To all parties the result must be bad—to the medical man who does the work, because it tempts him to make hasty diagnosis, give rule of thumb opinions, and exhibit sham medicines; to the profession at large, because it diverts into the pauper channel a vast class who are well able and half-willing to pay an adequate fee; to the artisan himself, because it induces him to adopt a false economy in medical matters, and to be satisfied with doctoring which in the long run cannot be good, because it is not sufficiently paid for.

We do not in the least mean to infer that the provident dispensary or the contract club are without their uses. There is a class just above the destitute, but far below the opulent artisan or comfortable shop-keeper, who could thus obtain something like medical attendance without applying to an hospital in *forma pauperis*, but we venture to say that this class does not constitute one-tenth of those who avail themselves of one or other of the many methods of contract doctoring.

Dr. Tweeddale goes further still, and maintains that the effect of the wide-spread system of contract doctoring in Australasia is to increase seriously the rate of mortality, and thus imperil the stability of insurance companies, whose statistical basis it is that their customers, as a rule, receive all the medical care which the profession can give them. He says:

"One factor of the problem, to assess the value of an average human life in this colony, I do not think has hitherto been taken into consideration, and that is the system of contract medical attendance. Well-to-do tradesmen, professional men, magistrates, and even mayors of boroughs, are not ashamed to belong to benefit societies, and take advantage of the services of the medical men of the club they belong to, and make use of the medicines supplied them at a mere nominal cost. However well this system may be adapted to the necessities of the working classes, who are not in a position to pay a medical man—yet cannot be allowed to linger in sickness without medical attendance—yet what can those who can well afford to

pay a medical man expect when they regularly employ the club doctor? Of course, they get his services together with his or the club dispensary's medicines; but whether they get full results of his judgment and scientific training is an open question. What members of any profession or trade give more than an equivalent of brains or goods for an amount tendered them? Surely it is but just to infer that the public get no more than the value of their money, which in this case is little enough. The sooner life insurance offices set their faces against the system of contract doctoring, either by a direct charge for the extra risk, or making voidable all policies in the event of death under this condition, the better chance they have of avoiding a certain though hitherto uncalculated loss.

## Notes on Current Topics.

### Scarlatina in Ireland.

WE regret to observe from the latest report of the Irish Registrar-General that the large diminution in the number of deaths from scarlatina which we reported last week was illusory, and that a considerable increase in the registered mortality from that disease has occurred within the last week. The deaths in Dublin and the suburban districts have been 26, or 8 more than last week.

In Coleraine the epidemic had attained alarming dimensions. The Irish Society's schools, at which there are generally upwards of 600 children in daily attendance, had been closed, the disease having attacked numbers in almost every family. Indeed, there were only seventy-eight in the infant school out of the average of 260 on the rolls, and an almost equally small proportion in the other two. The National School had been shut nearly a fortnight from the same cause, and numerous deaths had taken place, scarcely a single quarter of the town being free from the disease. The outbreak was preceded by several cases of fever, and there are yet several patients in the Poor-law Union Hospital.

### Adulteration Act.

DURING the past year, Dr. Tidy, Officer of Health for Islington, has examined eight samples of black tea, twenty of green tea, fifty-four of coffee, four of chicory, one of bread, twenty-six of pepper, twelve of butter, fourteen of mustard, and thirteen of milk. Nine samples were submitted to him by the public—viz., eight of milk and one of pepper. In five cases the inspector prosecuted. One tradesman was fined 20s. and 2s. costs; three 5s. and 2s. costs; and one 5s. and 4s. costs. In the case of the samples submitted by the public, two samples of milk and one of pepper were pure. In two cases of milk it was certified that they may or may not have been adulterated; in the four other cases of milk, that they were adulterated. We lately referred to the opinions of other medical officers of health on milk. We now give Dr. Tidy's, as stated in his annual report:—"As regards milk, I think it right to explain to you that it is an article having a variable composition. There are rich milks and poor milks, but both genuine. Therefore, before I certify that a milk is adulterated, it must fall below the composition of what I have found in some cases to be that of poor but genuine milk. If it is just over this, the milk is very doubtful, but

possibly may be genuine. I then certify that it may or may not be adulterated. This is the course I have always pursued and intend to pursue, because I believe it to be a correct one."

It is to be observed that Dr. Tidy does not tell us the lowest quality he passes.

### Visitation of Examinations.

THE Branch Medical Council in Ireland, not considering it expedient to select the visitors of examinations which the Executive Committee have asked them to nominate, have addressed the following letter to the various licensing bodies :—

Branch Medical Council (Ireland), 35 Dawson Street,  
Dublin, 5th October, 1874.

SIR,—I am directed by this Branch Council to inform you that a letter has been received from the President of the General Medical Council, requesting this Council to furnish to the Executive Committee of the General Council the names of such gentlemen as would be willing to act as visitors of examinations, and in accordance therewith, to request that you will be so good as to take steps to ascertain what members of your body will be willing to undertake such duty, and furnish me with their names and qualifications on or before Tuesday, the 13th inst.

The terms on which the appointments will be made are, that each person to be appointed will hold himself in readiness to visit and report upon such examinations, held in the United Kingdom, as he may be called upon to attend, the rate of remuneration to be as follows : Travelling expenses, together with a fee of five guineas a day, whilst engaged in the visitation, and an allowance of one guinea a day for hotel expenses.

I am, Sir, your obedient servant.

W. ED. STEELE, M.D., Registrar.

The Council of the Irish College of Surgeons have therefore forwarded a copy of it to each of the Fellows, asking them to send in their names if they are willing to serve.

### London Hospital Saturday Fund.

A LARGE meeting was held in Hyde Park on Saturday, under the Presidency of Archbishop Manning, who delivered an able address in support of the movement. We are sorry to interpose an objection to the cause of charity, but from the outset the fund has not been well managed, nor have the counsels of the hospital authorities, or the profession, been even indirectly sought in its promotion. We are not the only objectors, and sincerely do we trust that in the distribution of the fund nothing may crop up from behind to disgust contributors and deter working men generally from future honourable support to our hospitals. Here is what *The Observer*, one of our leading lay contemporaries has to say on the subject :—

"Hospital Saturday may be a good movement, but its promoters should not go out of their proper course to procure subscriptions. It is essentially a working man's fund, and subscriptions should be invited of working men only. Grand days at the Crystal Palace, amateur performances at fashionable halls, and special entertainments at theatres in its aid are entirely out of keeping with the ostensible character of the movement, while the sending out of a number of boys decked with scarlet sashes bearing the words "Hospital Saturday," and carrying boxes for the collection of indiscriminate subscriptions, is not only a degradation of the movement itself, but an insult to the institutions it is intended to benefit. Surely our hospitals are not in such straitened circumstances that they are obliged to resort to street-begging for their support. If they are, what becomes of the boasted charity of

England? We do not for a moment doubt that the promoters of Hospital Saturday are thoroughly earnest in their endeavours to promote the fund, and that in introducing the street begging-box system they intended well, but we are obliged to say that they are mistaken. Street-begging, no matter whether of the ordinary character, or in an organised form, is in every way objectionable, and ought to be discouraged. While we shall be happy to support any legitimate measure which may aid so excellent an object as that of the promoters of this mission, we must enter a protest against a scheme which cannot fail to bring any fund for which it is employed into public contempt."

### Poor-law Guardians as Sanitary Executants.

THE comments which we made last week upon the impolicy of confiding the execution of important Acts of Parliament—such as the Public Health Act—to half-educated and unintelligent Poor-law guardians received a cogent illustration last week. Our readers have been made aware that the criminal practice of inoculating small-pox has lately been revived in some districts in Ireland, and some feeble and ineffectual attempts have been made by the guardians to put a stop to the propagation of disease in this way. The institution of prosecutions is vested, as we know, in the guardians; yet we observe that in the Swineford Union an active contingent of the board is not only careless in the matter, but is actually in favour of small-pox inoculation, and would doubtless patronise the practice if the law allowed them to do so. At the last meeting of that board the relieving officer and Drs. O'Grady and Bourke reported on the prevalence of small-pox. The cases were confluent, and of a bad type, and stated that from all they could learn eight cases in Foxford were contracted through inoculation.

Thereupon three of the ratepayers' representatives declared that they were in favour of inoculation, and enunciated their opinion that "vaccination was a perfect failure," and more of the same tenor. A perusal of the reports of proceedings of the guardians in their capacity of sanitary authorities, which we publish from week to week in our Irish Poor-law Supplement, shows that the great majority of these gentlemen hold sanitation and cleanliness in the profoundest contempt. We greatly fear that the light which has been thrown upon the subject by these further utterances afford us no hope that the Public Health (Ireland) System will be saved from the limbo to which the Nuisances Removal and Disease Prevention Acts have been relegated by the incompetence and negligence of their administrators.

### Sanitary Appointments in Ireland.

THE Local Government Board have stated in a letter addressed to the Sligo Board of Guardians—*Firstly*, that a dispensary medical officer *may* hold at the same time the offices of sanitary medical officer and consulting sanitary officer; *secondly*, that the sanitary authority *must* appoint a consulting sanitary officer whether they like it or not; *thirdly*, that the sanitary authority *may* pay its consulting officer by an occasional fee where his advice is asked for if they see fit to do so.

SURGEON-GENERAL C. A. GORDON, M.D., C.B., has sailed for India, to assume his duties as Principal Medical Officer of the Madras Army.

### Ergotin Injections in Prolapsus Ani.

VON LANGENBECK, of Berlin, announces that he has lately been treating prolapsus ani "with astonishing success" by hypodermic injections of a solution of ergotin (five to fifteen parts to one hundred of distilled water). He replaces the bowel, and inserting the point of the syringe about three centimetres in depth in the cellular tissue, throws in from one to two grains of ergotin. This should be repeated every three or four days, for three or four weeks, any hard faecal masses in the bowels being first removed by simple injection.

### The Value of High Powers of the Microscope in the Diagnosis of Blood-stains.

DR. JOSEPH G. RICHARDSON believes that we are now able, by the aid of high powers of the microscope (1-25th and 1-50th), to distinguish stains produced by human blood from those caused by the blood of the ordinary domestic animals, and this even after the lapse of five years. He says that the possibility of recognising blood corpuscles when dried *en masse* is associated with their possession of a cell-wall, which can be brought into view and measured. He says that the variation in size of the corpuscles in a particular animal is comparatively slight in fresh blood, and even in dried blood ought not to prove a difficulty in the hands of a careful microscopist. The red corpuscles of the domestic animals, such as the pig, sheep, ox, goat, horse, &c., are all smaller than those of man. If, therefore, an error were committed in referring a given specimen of dried corpuscles to man or domestic animals, the evidence obtained would only mislead one into assisting in the acquittal of a criminal, and not into aiding to convict an innocent person. It appears then, that there is a doubt remaining besides which few will deny that the ordinary juryman would be slow to credit the ability of a witness to distinguish such small differences. The subject is, however, well worthy of the attention of microscopists.

The method adopted by Dr. Richardson for examining blood-stains is to scrape small particles from the specimen, reduce them to a fine dust upon a slide, cover with thin glass, and then to irrigate the preparation with a 3 per cent. solution of common salt. A drop of aniline is next allowed to come in contact with the blood for half a minute, and thereafter replaced by salt solution.

### The Late Dr. Anstie.

WE have received a carte-de-visite portrait of the late Dr. Anstie from Messrs. Fradelle and Marshall's Medical Gallery. It is in every way a pleasing and characteristic likeness of this accomplished physician, whose premature and sad death we all deplore.

We believe a considerable sum has already been promised for the Memorial Fund.

At a meeting of the Committee of the Hospital Out-patient Reform Association, held at 27 George Street, Hanover Square, it was proposed, by Dr. Alfred Meadows, seconded by Dr. Joseph Rogers, and unanimously resolved:—"That this committee having heard with unfeigned regret of the premature death of Dr. Anstie, desires to express its deep sense of the loss which the

profession has thereby sustained, especially as regards the cause of medical reform, in which he was an earnest and able worker. The committee remembers with gratitude his efforts on behalf of the objects of this association, and appeals with confidence to the members of the association in behalf of the Memorial Fund now being raised to perpetuate the memory of one, who for earnestness of purpose, integrity, and straightforwardness, was a bright example to all who are interested in the cause of medical relief." Mr. H. Nelson Hardy, honorary secretary, proposed that a circular letter embodying the above sentiments should be sent to each member of the association. This was seconded by Dr. James Davison, and carried unanimously.

Dr. Anstie was to have delivered the oration at the Medical Society of London this year.

### Model Lodging-Houses.

THERE are times when the question of the dwellings of the poor seems to come forward with unusual force, and the action of railway increase has undoubtedly been to make the housing of town populations more difficult.

The attempts made in various directions to improve the dwellings of poor citizens have always had our support, though at times we have felt misgivings as to the possible evil that might be mixed up with the good.

Our fears have been increased on finding that they were shared by many to whom we mentioned them, and by some who had watched the results were said to be more than well founded.

We now find that Dr. Meymott Tidy has, in his annual report to the Islington Vestry, come forward with a positive declaration that calls for careful consideration by all philanthropists.

We will give his exact words about model lodging-houses, commending them to the attention of all concerned:—

"I am quite aware that there are not a few who upon a chance visit to our London courts, hold up their hands in utter dismay and astonishment, never having apparently once imagined there were such places before. Anything below a row of artisans' cottages they had never once supposed could be in existence. Where the poor lived, and that some families were compelled by small means to live in a single room, was a matter they had never dreamt of. I can quite understand that the comparison they draw for the first time between a labourer's single room, where everything from cooking to sleeping has to be done, and the luxuriantly furnished drawing-room they had just left, must have been startling. Forthwith (with the experience possibly of this single room, in a single house, of a single court) they commit to press painful and sensational stories respecting 'The Dwellings of the Poor.'

"Far be it from me to say they are all we could wish, but I believe their condition is, as a rule, vastly exaggerated. It is easy enough for philanthropists (I admit the debt we owe them, but that must not shut our eyes to what is erroneous in their creed)—it is easy enough for them to talk loudly, and newspaper editors to write warmly on what the dwellings of the poor are, and what the dwellings of the poor should be. The poor do not want drawing-rooms. If they had them they would not know what to do with them, for they have no use for them. But I am bound to confess (sadly deficient in sanitary regulations as I admit many houses in our poor localities are) that I infinitely prefer them, with all their disadvantages, to the elegant architectural buildings some good philanthropists have erected (all honour to them for doing so, although I believe them mistaken), called *model lodging-houses*. From a social point of view I have reason to know that they are worse than failures. We are told 'they are more pleasing to the eye of the passers-by.' That I admit; and when you

have said that you have said all you can say for them. Cleaner outside they may be, but it is a cleansing only of the outside, and the driving inside of a nest of evils I would rather were external, because, if external, they are easier to cope with. Long, dark passages, with rooms on each side, like so many horse-stalls in a nobleman's stable, tenanted by different families, is not a provision likely to render the poor better, morally, socially or religiously. If you deal with the poor in masses, and house them in such a manner, it is absurd to be astonished when they take the hint and forget what is due to themselves. I am strongly of opinion that congregating the poor in large numbers in these huge erections is a great mistake, and I feel it is my duty as your health officer (while conscious that possibly I shall be misunderstood) to place my opinions before you."

### Pharmacy in Ireland.

It would seem that the Irish chemists and druggists have at length completely broken with the Apothecaries' Hall, with whom they had been so long endeavouring to effect a coalition. They are now throwing themselves into co-operation with the College of Physicians. At the last meeting of the London Pharmaceutical Society, the Secretary having read a communication received from the Chemists and Druggists' Association of Ireland on the subject of extending the Pharmacy Act to that country, the Council resolved itself into a committee to consider this communication, and ultimately the following resolution was unanimously carried:—

"That it is desirable to extend the provisions of the Pharmacy Act to Ireland, and that the Secretary be instructed to inform the Chemists and Druggists' Association of Ireland that, though this Council cannot undertake to frame any measure for this purpose, should such be submitted to the Pharmaceutical Society or Parliament, every consideration would be given to it; and in the meantime the following gentlemen are appointed to conduct, in conjunction with the Secretary, a friendly correspondence with the Chemists and Druggists' Association of Ireland respecting the provisions desirable to be embodied in legislation: The President, Vice-President, Messrs. Betty, Brown, Greenish, Hampson, and Sandford."

### Law for Doctors.

A CORRESPONDENT, Dr. Berry, of Wigan, states in our issue of to-day a very anomalous condition of affairs, but one which arises, we imagine, rather from the unacquaintance of the magistrates with the law, or their prejudice in favour of the lawyers. He narrates that an unqualified medical practitioner escaped punishment because the magistrates of Durham held that the absence of his name from the Medical Register was not sufficient proof that he was precluded from practising. The next week, in the Manchester Police Court, a person was fined for practising as an attorney without certificate, although it was shown that he was acting for a duly-licensed attorney, and although he had had a certificate some time ago.

Our correspondent draws a very just parallel between these cases, and naturally concludes that there is one justice for the doctor, and another for the lawyer, but we have our doubts that the law is as bad as the decision of the Durham magistrates would make it appear to be, and as we have little respect for the legal acumen of such gentlemen, we do not hesitate to say that their reading of the Medical Act was quite wrong. The 40th section declares that "Any person who shall wilfully use . . any description implying that he is registered under this

Act, or that he is recognised by law as physician, &c. . . shall for such offence pay £20."

To our comprehension this clause makes registration the test of qualification, and its absence a *prima facie* proof that legal qualification does not exist. It is greatly to be regretted that such a decision as that given by the Durham magistrates has never been taken to the superior courts, for we believe it would be at once reversed by a more competent and astute tribunal.

THE Chair of Physiology at King's College is now vacant.

SURGEON-MAJOR PORTER, Assistant-Professor of Military Surgery at the Royal Victoria Hospital, Netley, has been presented with the bronze cross by the French Societies for Aiding the Sick and Wounded in War, in recognition of his services during the late Franco-German War.

ON October 1st the regimental hospital establishment at Aldershot ceased to exist, and there are three "Station Hospitals" at the Camp instead. One is at the North Camp, one at the South Camp, and one at the Permanent Barracks, with a medical officer appointed to each.

### American Mineral Waters.

THE *Boston Medical and Surgical Journal* has a somewhat amusing and suggestive article on the fashion of drinking mineral water.

The composition of a famous American sample, called "Nature's Great Remedy," is given as follows:—

ONE UNITED STATES GALLON CONTAINS		
Sulphate of potash	.. ..	0.101 grains.
Chloride of sodium	.. ..	0.447 "
Bi-carbonate of soda	.. ..	0.218 "
Bi-carbonate of lime	.. ..	4.168 "
Bi-carbonate of magnesia	.. ..	0.867 "
Sulphate of lime	.. ..	0.811 "
Silica and alumina	.. ..	0.043 "
Protoxide of iron	.. ..	2.161 "
Organic matter ("crenic acid")	.. ..	2.888 "

From which it appears that every gallon contains 11.674 grains, or 1-40th of an ounce of mineral matter, &c., and is therefore about the same strength as that found in most of the wells in the neighbourhood of Boston.

To manufacture "Nature's Great Remedy" at home, for those whose well-water is not sufficiently impure, a recipe is given corresponding with the above quantities, but it is humorously suggested that if protoxide of iron be not readily obtained without troubling the market, it may be easily furnished by stirring the mixture with an iron spoon, or allowing a board nail to remain in the mixture over-night. This is hardly fair—even in fun. The advocates of the water might just as well tell our learned contemporary to let his patients eat with an iron spoon instead of taking chalybeate mixtures. Another water from the same company contains less of the minerals, according to the State assayer, but "it is highly charged with sulphuretted hydrogen." This, it is said, can be "easily obtained by using for a vehicle the water from some well near to which runs a drain." Again, we may object that this is not a fair comment. Sulphuretted hydrogen is not sewer-gas, though the former is sent in the latter.

## STUDENTS' COLUMN.

## LESSONS ON PRESCRIPTIONS AND THE ART OF PRESCRIBING. (a)

By W. HANDSEL GRIFFITHS, Ph.D., L.R.C.P.E.,  
Licentiate of the Royal College of Surgeons of Edinburgh, Honorary  
Member of the Ontario College of Pharmacy, Librarian to  
the Royal College of Surgeons in Ireland.

## LESSON VII.

## POSOLOGY.

WE have to-day to consider the extremely important subject of dosage. It is very necessary for you at the outset to understand that a medicine will exert a very different effect according to the dose administered; thus, tartar emetic in doses of from 1-16th to 1-6th of a grain acts as a diaphoretic; in doses of from 1-6th to  $\frac{1}{2}$  grain it will act as a depressant; and in doses of from 1 to 2 grains it will produce emesis.

There is one matter of great interest and import connected with posology to which sufficient attention is not paid by the generality of practitioners—I allude to the modification of action exercised by a medicinal agent according as it is administered in one large dose or in several small doses at stated intervals. We have yet much to learn concerning this matter, and the subject opens up for you a wide field for original investigation. One of the most pungent writers in one of the most incisive articles which ever issued from his pen thus expresses himself: "No greater service could be performed by the colleges or the great medical societies than the formation of a committee of competent men for the special investigation of this question of dosage; for it is a subject which is as yet only in its infancy, and the best knowledge which exists about it is undoubtedly confined to a very small section of the medical profession."

I have recently published, for the use of students and practitioners, a posological chart, (b) in which I have endeavoured as far as possible to assist the memory and to facilitate reference. I purpose in this lesson to give you such a summary of the contents of this chart as will enable you to obtain and retain such a knowledge of official dosage as will be sufficient for the exigencies of ordinary practice. I use the term "official dosage" advisedly, for exception must be taken to many of the posological dicta of the British Pharmacopœia. For instance, the Pharmacopœia directs as a maximum dose of tincture of digitalis 30 minims, whereas, half an ounce is not unfrequently given in delirium tremens. A drachm is the maximum dose recommended for tincture of henbane, but half-an-ounce of that preparation is often given with benefit to maniacal patients. The minimum dose stated for tincture of belladonna is too large, and the maximum dose is too small. On the other hand, the maximum dose recommended for tincture of nuxvomica would tetanise many a patient. A drachm is allotted as the maximum dose of succus conii, but I have myself seen an ounce of that preparation administered with great benefit. The Pharmacopœia specifies 5 grains as the extreme dose of sulphate of quinine, a dose which would be utterly useless in many cases of intermittent fever, &c. Again, the minimum dose recommended for strychnia and the salts of morphia is much too large.

Less than a year ago the late Dr. Anstie directed the attention of the profession to these defects in our "official dosage." (c) You will understand, therefore, that although in apportioning doses I have followed the British Pharmacopœia as an authority, I dissent in many instances from the recommendations in that volume. The doses

which I am about to give are those for adults, so that I will ask your attention to the methods of Gaubius and Young for regulating doses according to age.

## GAUBIUS' METHOD OF REGULATING DOSES ACCORDING TO AGE.

Ages.	Proportional Quantities.	Doses.
<i>For an adult</i>	<i>suppose the dose to be.</i> 1	<i>or 60 grains.</i>
Under 1 year .	will require . 1-12	5 "
" 2 years .	" . $\frac{1}{8}$	7 $\frac{1}{2}$ "
" 3 " .	" . $\frac{1}{6}$	10 "
" 4 " .	" . $\frac{1}{4}$	15 "
" 7 " .	" . $\frac{1}{3}$	20 "
" 14 " .	" . $\frac{1}{2}$	30 "
" 20 " .	" . $\frac{2}{3}$	40 "
Above 21 " .	the full dose . —	60 "
" 65 " .	the inverse gradation of the above	

## YOUNG'S METHOD OF REGULATING DOSES ACCORDING TO AGE.

"For children under twelve the doses of most medicines must be diminished in the proportion of the age to the age increased by 12." Thus:—

$$\begin{aligned} \text{For one year, } \frac{1}{1+12} &= \frac{1}{13} & \text{For four years, } \frac{4}{4+12} &= \frac{1}{4} \\ \text{For two years, } \frac{2}{2+12} &= \frac{1}{7} & \text{For six years, } \frac{6}{6+12} &= \frac{1}{3} \\ \text{For three years, } \frac{3}{3+12} &= \frac{1}{5} & \text{\&c.} & \text{\&c.} \end{aligned}$$

Not only must age be taken into consideration in apportioning a dose, but sex, habit, temperament, idiosyncrasy, disease, race, and climate must all receive due consideration. It is unnecessary for me to do more than remind you that certain drugs, as opium, are very badly borne by children.

In the following posological summary I will adopt the classification which I have used in my chart.

## INORGANIC SUBSTANCES.

## METALLOIDS.

Carbo ligni . . .	} gr. xx.—3.
" animalis pur. . .	
Sulphur sublimat. . .	} gr. xx.—3.
" præcipitat. . .	
" Iodidum . . .	gr. $\frac{1}{2}$ —ij.
Phosphorus . . .	gr. 1-40th—1-10th.
Iodum . . .	gr. $\frac{1}{2}$ .

## ACIDS.

Dilute acids, average dose ℥v.—xx, except acid. hydrocyanic. dil., the dose of which is ℥ii.—viii., and acid. acetic. dil., the dose of which is ʒi.—ii.

The dose of acid. sulph. aromat. is the same as that of the dilute acids.

The dose of acid. sulphurosum is ℥xxx.—ʒj.

The following are the doses of the solid acids:—

Acid Arseniosum . . .	gr. 1-60th—1-12th.
" Carbolic. . . .	gr. i.—iii.
" Tannic. . . .	} gr. ii.—x.
" Gallic. . . .	
" Benzoic. . . .	gr. x.—xv.
" Citric. . . .	} gr. x.—xxx.
" Tartaric. . . .	

## SALTS OF THE ALKALIES.

Ammonium.—Dose of all the salts is gr. v.—xx, except the carbonate, the dose of which, as a stimulant, is gr. iii.—x, and as an emetic, gr. xxx., well diluted.

Potassium.—The dose of sulphurated potash is gr. iii.—vi.; that of iodide of potassium is gr. ii.—x; that of the

(a) Corrected from shorthand notes by one of the author's pupils.

(b) "Posological Tables: being a Classification of the Doses of all Official Substances." Second Edition. London: Baillière, Tindall, and Cox, King William Street, Strand.

(c) Practitioner, vol. ix., p. 259. 1873.

bromide, carbonate, chlorate, and nitrate is gr. v.—xxx.; that of the bicarbonate is gr. x.—xl.; and that of the acetate, citrate, sulphate (*purgative*), tartrate, and acid tartrate is gr. xv.—3. The dose of either of the two latter salts when they are used as *purgatives* is ʒii.—iv.

*Sodium*.—Arsenate, gr. 1-16th— $\frac{1}{2}$ ; valerianate, gr. i.—v.; hypophosphite, gr. v.—x.; dried carbonate, gr. iii.—x.; carbonate, gr. v.—xxx.; acetate, biborate, bicarbonate, and sulphite, gr. x.—3; effervescing citro-tartrate, ʒi.—ii.; tartarated soda, ʒii.—iv.; and phosphate and sulphate, ʒii.—3.

*Lithium*.—Carbonate, gr. iii.—vi.; citrate, gr. v.—x.

#### SALTS OF ALKALINE EARTHS.

*Barium*.—The dose of the chloride is usually given in text-books as gr.  $\frac{1}{2}$ —ii.; this, however, is much too large a dose; it should not be administered in doses exceeding gr. 1-16th—1-12th.

*Calcium*.—The dose of the hypophosphite of lime is gr. v.—x.; that of the chloride and phosphate is gr. x.—xx.; and that of the precipitated carbonate and of prepared chalk is gr. x.—3.

*Magnesium*.—The dose of magnesia and of carbonate of magnesia is gr. x.—3; that of sulphate is ʒi.—iv.

#### SALTS OF THE EARTHS.

*Aluminum*.—Alum as an *astringent* is given in doses of gr. x.—xx., and as a *purgative* gr. xxx.—3.

#### SALTS OF THE METALS PROPER.

*Antimonium*.—The dose of tartar emetic as a diaphoretic is gr. 1-16th—1-6th; as a depressant, gr.  $\frac{1}{2}$ — $\frac{1}{2}$ ; and as an emetic, gr. i.—ii. The remaining preparations of antimony—viz., black antimony, oxide of antimony, and sulphurated antimony—are all given in doses of gr. i.—iv.

*Argentum*.—Nitrate, gr.  $\frac{1}{2}$ — $\frac{1}{2}$ ; oxide, gr.  $\frac{1}{2}$ —ii.

*Bismuthum*.—Oxide, gr. v.—xv.; carbonate and sub-nitrate both gr. v.—xx.

*Cerium*.—Oxalate, gr. i.—ii.

*Cuprum*.—Sulphate, gr.  $\frac{1}{2}$ —ii., or, as an *emetic*, gr. v.—x.

*Ferrum*.—Arsenate, gr. 1-16th— $\frac{1}{2}$ ; dried sulphate,  $\frac{1}{2}$ —iii.; sulphate, granulated sulphate, reduced iron, and iodide of iron, all gr. i.—v.; tartarated iron, phosphate, magnetic oxide, citrate of iron and quinine, citrate of iron and ammonia, all gr. v.—x.; saccharated carbonate, gr. v.—xx.; hydrated peroxide, gr. v.—xxx.; and moist peroxide, ʒii.—iv.

*Hydrargyrum*.—Perchloride, gr. 1-16th— $\frac{1}{2}$ ; red iodide, gr. 1-16th— $\frac{1}{2}$ ; green iodide, gr.  $\frac{1}{2}$ —iii.; subchloride, gr.  $\frac{1}{2}$ —v.; hyd. c. creta, gr. iii.—viii.

*Manganesium*.—Sulphate as a *purgative*, ʒi.—ii.

*Plumbum*.—Iodide, gr.  $\frac{1}{2}$ —i.; acetate, gr. i.—iv.

*Zincum*.—Chloride, gr.  $\frac{1}{2}$ —i.; acetate, as a *tonic*, gr. i.—ii.; sulphate, as a *tonic*, and valerianate, gr. i.—iii.; carbonate, gr. i.—v.; oxide, gr. ii.—x.; acetate, as an *emetic*, gr. x.—xx.; sulphate, as an *emetic*, gr. x.—xxx.

#### ORGANIC SUBSTANCES.

##### VEGETABLE PRODUCTS.

*Elaterium*.—Sediment from juice of fruit. gr. 1-16th— $\frac{1}{2}$ .

*Capsicum*.—Fruit.

*Digitalis*.—Leaf.

*Podophyllum*.—Resin.

*Rhus Toxicodendron*.—Leaf.

*Ipecacuanha* (*expectant*).—Root.

*Opium*.—Inspissated juice of fruit.

*Cambogia*.—Gum-resin.

*Nux Vomica*.—Seeds.

*Scilla*.—Corm.

*Veratrum Viride*.—Rhizome.

*Stramonium*.—Leaf.

*Aloes*.—Inspissated juice of leaf.

*Jalapæ Resina*.

*Lupulin*.—Powder of scales.

*Aconitum*.—Leaf.

*Colchicum*.—Corm.

*Colocynth*.—Pulp.

*Conium*.—Leaf.

*Piper*.—Berries.

*Sabina*.—Tops.

*Sagapenum*.—Gum-resin.

*Scammonium*.—Resin and gum-resin.

*Staphisagria*.—Seeds.

*Camphora*.—Concrete volatile oil. gr. i.—x.

*Myristica*.—Seeds. gr. v.—xv.

*Balsamum Peruvianum*. M v.—xv.

*Ammoniacum*.—Gum-resin.

*Assafoetida*.—Gum-resin.

*Benzoinum*.—Balsam.

*Calumba*.—Root.

*Cardamomum*.—Seeds.

*Caryophyllum*.—Flower-buds.

*Pimenta*.—Berries.

*Podophyllum*.—Root.

*Quassia*.—Shavings.

*Rheum*.—Root.

*Serpentaria*.—Root.

*Styrax Preparatus*.—Balsam.

*Tolutanum*.—Balsam.

*Canella*.—Bark.

*Cascarilla*.—Bark.

*Catechu*.—Extract of leaves.

*Cinnamomum*.—Bark.

*Coriandrum*.—Fruit.

*Ergota*.

*Galbanum*.—Gum-resin.

*Gentiana*.—Root.

*Guaiaacum*.—Resin.

*Ipecacuanha* (*emetic*).—Root.

*Jalapa*.—Root.

*Kino*.—Inspissated juice.

*Lactucarium*.—Inspissated juice.

*Myrrha*.—Gum-resin.

*Simarubra*.—Root-bark.

*Terebinthina Canadensis*.—Oleo-resin.

*Uva Ursi*.—Leaves.

*Valeriana*.—Root.

*Zingiber*.—Rhizome.

*Bucco*.—Leaves.

*Cusparia*.—Bark.

*Mastiche*.—Resin.

*Ruta*.—Leaves.

*Absinthium*.—Flowering herb.

*Cinchona*.—Bark.

*Copaiba*.—Oleo-resin.

*Cortex Winteri*.—Bark.

*Krameria*.—Root.

*Matico*.—Leaves.

*Pareira*.—Root.

*Santonica*.—Flower-heads.

*Senega*.—Root.

*Sumbul*.—Root.

## Literature.

### STATISTICS OF FAMILIES IN THE UPPER AND PROFESSIONAL CLASSES. (a)

THE author of this interesting little work is an actuary of the National Life Assurance Company. He tells us that in 1871 the directors of this society found they had no data as to the rate of mortality prevailing among children in the upper and professional classes sufficiently extensive and reliable to render it prudent to use them as a basis on which to found the necessary tables of premiums. It was decided, as being the safest course, to endeavour to collect, by direct communication with a sufficient number of parents in the station of life alluded to, accurate particulars as to the dates and birth and death of their own children, and of their brothers and sisters, and from this information to construct a table of mortality.

Applications, in the form of a lithographed letter, stating the object of the inquiry, were addressed to members of the clerical, medical, and legal professions, and to a large number of other gentlemen and noblemen in England and Wales, and forms were attached which the persons addressed were requested to fill up. These forms were two in number—the first adapted for information relative to the informant's own children, whether the issue of one or more marriages; the other for information respecting the issue of the marriage of his father or mother—i.e., his brothers' and sisters.

In a great majority of the cases the particulars appear

(a) "Statistics of Families in the Upper and Professional Classes." By Charles Ansell, Jun. London: Layton, Fleet Street. 1874. Pp. 88.

to have been stated with so much care and attention as to leave no reasonable doubt of their complete reliability. One gentleman, after stating the particulars of his somewhat numerous offspring, winds up by a pictorial illustration of his satisfaction at there being no prospect of a further increase.

Of the 49,099 children of which full particulars were given, there were born alive 24,640 males and 23,400 females, and born dead 627 males and 432 females.

The Northampton tables were drawn up by Dr. Price, from births and deaths in Northampton from 1735 to 1780, the Carlisle table was published in 1815; and the Equitable Assurance table is founded on 21,398 persons assured in its books.

It has long been known that the death-rate of the more comfortable classes is far lower than that of the poorer. The expression "struggle for existence" well expresses the difficulty the lower classes have in keeping their children alive, and the writings of Malthus and Mill have made this point very clear.

Any large community, whether town or country, are mainly composed of the poorer classes, or the working classes, and hence the average rate of mortality of society at large approximates far more to that of the working classes than to that of the wealthy classes. Poor food and clothing, crowded dwellings, drink, and neglect are, of course, common among the poor. "When the dominant feeling of parents with regard to their children is that they are a burden to them, the chances of the latter succumbing to the perils of infancy and childhood are seriously increased." In many instances the poorer classes have a direct pecuniary interest in the death of their children when they belong to insurance offices.

Comparing the mortality of the two sexes, as shown by the *upper class* experience, it will be seen that, with the exception of a short interval at about the age of two, the female mortality is less than that among males from birth up till ten; that from ten to seventeen the male death-rate is considerably lower than the female; and after that age the mortality among females is materially lower than among males. In the *English Life* tables the death-rate of females between nine and thirty-eight is higher than males of the same ages. This is because among the upper and professional classes it is upon men that the wearing toil and anxieties of life chiefly press.

The mean age at marriage, as disclosed by the upper class tables, is very high, and is about thirty for males and twenty-five and a half for females.

The average number of children to a marriage is a most important feature in this table. Some couples had 18 children, and even 25 in one case. Clergymen seem, as a rule, to have 5.25 children, lawyers 5.18, and doctors 4.82.

Child-bearing in a few cases did not terminate until the age of fifty-three; but thirty-eight years is the mean age of mothers at the date of the birth of their last child.

The mortality deduced from the upper class data is to that of the Carlisle table in the proportion of 52 to 100 under one year of age; 26 to 100 between one and five; 61 to 100 between five and fifteen; 104 to 100 between fifteen and twenty-five; 91 to 100 between thirty-five and forty-five; 77 to 100 between forty-five and fifty-five; 71 to 100 between fifty-five and sixty-five; and 81 to 100 between sixty-five and seventy-five.

By the upper class tables the mortality is equal at the age of one and of sixty-nine; in the *English Life* tables it is equal at one and seventy-two. In the former table the rate of mortality at twenty-four equals that at fifty-six; in the latter that at sixty-five. In the former the mortality at three equals that at thirty-six; in the latter that at fifty-nine. Every writer on hygiene and statesmen should read this valuable work.

THE Professorship of Comparative Anatomy and Zoology at University College is vacant through the death of Dr. Grant.

## Correspondence.

### THE LAW FOR LAWYERS *VERSUS* THE LAW FOR DOCTORS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—On September the 26th, Mr. John Le Page was charged before the magistrates of Durham with having unlawfully, wilfully, and falsely used the name and title of surgeon in the township of Brandon and Byshottles, implying thereby that he was registered under the Medical Act of 1858, and contrary to sec. 40 of the said Act. The case against him was dismissed, it being held, as had been on a previous occasion, in the case of *Pedgrift v. Chevalier* (*Law Times*, vol. ii., p. 360), that the mere fact of absence of a person's name from the "Medical Register" was not sufficient to warrant a conviction under the section of the Medical Act. This man had wily engaged a qualified assistant, and both had signed the certificates.

On October the 5th, Mr. Robert Dalton Law was charged at the Manchester City Police Court, under the 37th and 38th Vict. cap. 68, sec. 12, with practising as an attorney without being in possession of the requisite certificate.

It was proved that he had acted without fee or reward, having appeared in a case for a duly licensed attorney; yet he was convicted, and fined £5, with the alternative of a month's imprisonment, the magistrate stating he had practised in the court on previous occasions; the full penalty of £10 would have been inflicted had he not acted for another, and this being the first case under the new Act.

Mr. Law had previously held a certificate, but owing to some circumstance or other had not one at the present time; he would therefore be similar to a medical man who had been erased from the "Register."

It is not long ago since a gentleman whose name had been removed from the "Medical Register" was summoned before the presiding magistrate at one of the London police-courts for practising as a surgeon, and the case was dismissed. These cases are analogous; yet in the one case we have a conviction, and in the other a dismissal.

We do occasionally hear of Justices' Justice, and here we have something in the same category. If a man violates the law of his country, why is he not punished accordingly?

Why have we a conviction in the one case and not in the other?

Why should lawyers be protected any more than doctors?

Why should medical men be compelled to register before holding any appointment, and pay £5 for such registration?

Of what use is medical registration at all if no protection is afforded?

Lastly, what will warrant a conviction against an offender if his name be absent from the "Register" and he fails to produce a medical qualification?

Now, Mr. Editor, is it not high time that there was some legislation in the matter? Does not the Medical Act of 1858 require amending, or another Act substituted, giving the medical profession some protection?

Can we ever hope to abolish quacks and quackery while the law is so flagrant on the subject? It is only a few weeks since a bone-setter's evidence was tendered and accepted in a court of law, and accepted, I presume, as scientific evidence. Doesn't the fact of a judge allowing this show his high appreciation of the medical profession?

Now, Sir, it is quite time irregular practitioners were put down by the strong arm of the law; but what can be done while the law stands as it is at present? Though one is willing to undertake the expense of a prosecution, a conviction is seldom attainable under the present Act. Can nothing be done? Is it not possible to get a bill passed amending the Medical Act of 1858, and afterwards legislate for the admission of members into the profession?—whether it be through the one portal system or through the many we have at present, with another added, as the C.M.B., matters not. We should first seek to have the rights of the existing members of our profession protected.

I am, Sir, yours, &c.,

WM. BERRY, M.R.C.S.

Wigan, October 8th, 1874.

### URÆMIC CONVULSIONS SIMULATING EPILEPSY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I would feel obliged by your publishing the following rather remarkable case in your valuable journal:—

On the 25th of September, 1872, whilst serving as surgeon on board H.M.S. *Research*, off the coast of Spain, I was hastily summoned from the ward-room to see John Ellis, æt. 33, gun-room steward, who had been seized with a fit whilst asleep on his chest in the steerage. I found him writhing in what appeared to be a well-marked attack of epilepsy. He was lying on the lower deck, tossing about convulsively, and frothing at the mouth; the pupils were dilated, face pallid and covered with a cold clammy perspiration. I unfastened the clothes from about his neck, dashed cold water in his face, and then waited to see him return to consciousness. This however, as will be seen, he never did. After some time spent in vain efforts to subdue, as we supposed, the epileptic seizure, both the staff-surgeon, Dr. O'Malley, and myself thought it better to have the patient brought to the sick bay, which was accordingly done. Every possible inquiry was made as to previous history, but we found it extremely difficult to obtain any reliable information from his messmates. No person seemed to know whether there had been any complaint of illness. The midshipman told me that Ellis had been in the habit of drinking about four glasses of rum daily for the last year and a half, or two years. After patient had been placed in bed a catheter was introduced into the bladder. No urine, however, made its appearance; this confirmed the diagnosis, previously arrived at by Dr. O'Malley and myself, that the case was one of congestion of the kidneys, causing suppression of urine, and the consequent circulation of urea in the blood, uræmic convulsions. Acting upon this opinion, every possible means were taken to get the kidneys to act. A hot bath was ordered, followed by a large enema of turpentine, castor-oil, and tepid water; friction, dry cupping, and constant turpentine stupes were used over both kidneys, but without avail.

Sept. 27.—Passed during the night about 5iv. of highly coloured urine, which was, on the application of heat and nitric acid, found loaded with albumen. Patient continued in much the same state; pupils were now contracted, face flushed, continually wanting to get of bed—indeed, so energetic were his movements, that it required a couple of strong men to restrain him; bowels were moved unconsciously, sordes appeared on the teeth and gums, scarcely any urine was passed, and low muttering delirium, with those certain harbingers of death, *flores attacis*, and *subultus tendinum*, set in during the night. It is unnecessary to continue a daily summary of this patient's case; suffice it to say that all efforts to relieve the kidneys were unavailing, death taking place on the 1st October, after an illness of seven days. A post-mortem was made under great difficulty, as, owing to the extreme heat of the weather, the body would not be permitted to remain on board more than six hours. Both kidneys were found enormously enlarged and congested, the right more particularly, and a number of small circumscribed abscesses were detected in each; the capsules were thickened and surrounded with a large quantity of fat; the liver was pale in colour, and hard, a good example of lardaceous disease. The captain would not allow us any more time, so we had to rest content with the very cursory inspection of the body which I have described. Greatly to our disappointment, we were unable to examine the condition of the encephalon and its contents. This case is, in my opinion, extremely interesting and instructive; it points out—1st. The great similarity between epileptic and uræmic convulsions; 2nd. The difficulties which sometimes attend a proper diagnosis between these two diseases in the absence of any history; 3rd. How long and continued drinking will infallibly cause extensive disease of both liver and kidneys; and 4th. The uselessness of any treatment, no matter how energetic, once the congestion has for any length of time established itself.

I am, yours truly,

EDWARD C. THOMPSON, M.B.

Infirmary, Omagh, 1st October, 1874.

## Medical News.

University of Cambridge—Dr. Bradbury, Lecturer in Medicine, gives notice that he will lecture

in the Old Anatomical Schools, on Tuesdays at 10 a.m., during the Michaelmas Term, commencing on Tuesday, October 13th. The Professor of Anatomy (Dr. Humphry) commenced his course of lectures on Practical Anatomy on Thursday, October 8th. The course on Anatomy and Physiology will commence on Friday, Oct 23rd. The latter course is intended for students in natural science, as well as for students in medicine, and is open without fee, except to those requiring a certificate.

**Promotion in the Indian Army**—Under the authority of the Secretary of State for India, it is notified that, although a certain period of regimental service is not required by the Royal Warrant of July 1st, 1873, as a necessary qualification for promotion to the administrative grade of the Medical Department, it will still rest with the Government of India to select for promotion to that grade officers possessing sufficient regimental experience to enable them to exercise supervision over military hospitals and regimental military staffs.

**South London School of Pharmacy**—On Wednesday, the 7th inst., the formal opening and distribution of prizes took place in the new and magnificent laboratory of this popular institution. Mr. Baxter, in distributing the prizes, delivered a short address of encouragement and advice to the large body of students assembled, taking as his text the motto of the school, "Systema Omnia Vincit," by which their labours would be aided and fostered. As a proof of the popularity of the school, and the value of its teaching, he mentioned that during the past session no less than 298 pupils passed the official examination of the Pharmaceutical Society, including six medical officers of health and eight purely analytical students. He then announced the following prizes: The Herbarium Prize of £5 to Mr. James Epps, of London; bronze medals to Mr. Cumine, of Southport, Mr. Fowler, of Torrington, Mr. Webb, of Chester; and seven certificates of merit to other students.

**Alarming Outbreak of Scarlet Fever in East London.**—At the last meeting of the Mile End Vestry a letter was received from the schoolmistress of an establishment for infants in the district, stating that three children formerly attending the school had died from scarlet fever. In spite of every precaution several other children had contracted the disease, and were away from the school. The writer added that she could not help thinking that the drainage, together with the overcrowded and dirty condition of some of the houses, tended to spread, if not to induce fever. In one house quite close to the school a child was lying dead, and yet six persons were sleeping in the same room. In reply to questions, Dr. Corner, the medical officer of health, stated that there had been a considerable number of deaths from scarlet fever in the district; but he failed to find evidence of great overcrowding. It was eventually decided to forward copies of the report sent up by a committee recommending disinfection of the house and the schoolmistress's letter to the School Board. At the weekly meeting of the Mile End board of guardians it was resolved, on the suggestion of Dr. Loane, the house doctor, to prohibit the friends of the inmates from visiting whilst the scarlet fever was so prevalent. In the Poplar district, comprising the three parishes of Bow, Bromley, and Poplar, a total of 48 cases of scarlet fever had been reported to the sanitary committee, of which 23 had proved fatal. Fourteen fatal cases were reported to the St. George's East Vestry at their last meeting, whilst in the Whitechapel district fevers of all kinds are prevalent, the enteric type predominating. At each of the boards general sympathy was expressed, and it was ordered that disinfectants in every instance be supplied, and that where necessary, to prevent the fever spreading, the bedding, &c., be entirely destroyed.

## Gleanings.

### Aneurism mistaken for Asthma.

THE proceedings of the San Francisco Medical Society refer to a case of death from aneurism, which was reported as "Asthma" by an ignoramus with a bogus diploma, or with no diploma at all. Similar cases, however, have occurred under the charge of regular and experienced physicians, who have failed to trace the asthmatic condition to its true source. It is only

by post-mortem examination that the true nature of the lesion has been ascertained. We are confident that many of the deaths attributed in past years to asthma, would have been proved to result from aneurism had an examination been made.—*Pacific Medical Journal*.

### Apthous Stomatitis communicated to Man through the Milk of a Cow affected with the same Disease.

THE symptoms commenced in less than half an hour after the ingestion of the milk. They consisted in vertigo, tingling in the ears, feebleness, afterwards delirium and hallucinations. On the second day, vomiting and diarrhoea, with abdominal pains set in, which promptly yielded to treatment by opium and subnitrate of bismuth. The fever, however, was not broken, and on the third day stomatitis appeared, with pyalism and the development of apthae on the inner surface of the lips and cheeks, on the palate, and the inferior surface and borders of the tongue. At the same time, there appeared a phlyctenular eruption on the hands, feet, perineum, and scrotum. The nervous disturbances, delirium, and insomnia were combated by opium, given in doses of fifteen centigrammes per diem, and the stomatitis by gargles of chlorate of potash. At the end of fifteen days the patient recovered. A remarkable detail of this observation, made by Dr. Van Varys, is that the wife and children of the patient had drunk milk from the same cow, and were not affected. At that period, an epidemic of apthous stomatitis reigned among the horned cattle in the country, and the milk of these animals was used, notwithstanding its virulent properties. The difference in the results Dr. Van Varys attributes to the fact that the milk drunk by the patient's family had previously been boiled. Experiments made by a veterinary surgeon of Nievre have demonstrated that milk subjected to a temperature of more than 80° loses its virus.—*New York Med. Jour.*

### Puerperal Mania—Treatment by Chloral and Bromide of Potassium.

THE patient, aged thirty years, had been suffering severe anxiety, previous to and during labour, from some domestic trouble. The position was transverse, and delivery accomplished by version. Following the labour were severe after-pains, for which morphia was administered. That night the pulse ran up to 130 per minute, the temperature to 102½°, and with this fever marked delirium set in. The delirium continued for two nights and one day, when the treatment, which had been morphia with veratrum viride, was changed to bromide of potassium with hydrate of chloral. Two hours after the latter remedies had been administered the patient slept, and on awaking was perfectly rational. This improvement continued.—*New York Med. Jour.*

### Delirium Tremens.

THE standard prescription for this condition at the Roosevelt Hospital, New York, is—

R Chloral hydrat., grs. xxx.,  
Potass. brom., grs. xl.

To be given at bed-time and continued through the day in smaller doses if necessary.

### Abortive Treatment of Boils.

THE *Cincinnati Lancet and Observer* has a note from Dr. C. B. Hall, stating that the following, applied to boils with a camel-hair pencil or feather, gives great relief in a very short time: Tincture of arnica flowers, 1 drachm; tannic acid, half a drachm; powdered acacia, half a drachm. The inflamed surface, and a little beyond all around, should be painted with the medicine every fifteen minutes, or as fast as it dries, till a good thick coating covers the part. The throbbing, tensive pain, and the intense tenderness will be promptly relieved; the redness will subside; the smooth, shining integument will shrink and become wrinkled, and comfort will succeed torment. If the boil be in the first stage, it will disappear without sloughing. If sloughs have already formed, it will be quickly separated, and the cure will be soon complete. The preparation should be used as soon as prepared.

### Chlorhydrate of Trimethylamin in Rheumatic Fever.

A NEW successful instance of the above has been communicated to the Therapeutical Society of Paris by Dr. Martineau. When called to the patient he found that the elbow had, since the morning, become red, enlarged, and painful, skin hot, pulse 90. Ten grains of the drug were administered.

The pain in the elbow had entirely disappeared, and the pulse had fallen from 90 to 65. No crisis or cardiac complication had occurred. The same treatment had been equally successful in a similar attack a year previously.

#### Treatment of Zona by Collodion and Morphia.

DR. BOURDON, Hôpital la Charité, after having tried a great many local means for treating the above disease, and checking the intense pain, has definitely adopted the following plan. Without opening the vesicles, he paints all the diseased surface with a combination of collodion and morphia—collodion one ounce, morphia eight grains. The mixture must be put on pretty thickly. The pain ceases from the second day, and at the end of seven or eight days, when the layer of collodion is removed, all the vesicles have disappeared, and there remains only a slight local redness.

#### Application for Burns.

M. LEBIGOT recommends the following mixture as having been very successful:—Cape aloes, four ounces; water, ten ounces; alcohol (90°), three ounces. The ingredients are to be melted together in a china plate over a slow fire, allowed to cool, and then filtered; after which three more ounces of alcohol are to be added. It is then ready for use. A tablespoonful of the mixture mixed with a teaspoonful of acetate of lead and twenty tablespoonfuls of water constitutes an excellent remedy. It is to be applied morning and evening on the burnt parts. —*Lancet*

#### Acute Articular Rheumatism.

At the Charity Hospital, New York, the following is in use as a local application:—

R Tinct. opii, ℥i;  
Spiritus chloroformi, ℥iss.;  
Linimenti saponis, ad Oj.—M.

This liniment is applied freely to the joints and immediately covered with cotton and oiled silk. The relief from pain afforded by this application has been gratifying. —*New York Medical Record*.

## NOTICES TO CORRESPONDENTS.

83 CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

SURGEON DUNNE, Dublin.—Communication declined with thanks.

DR. PROSSER JAMES and MR. LUNN on the VOICE.—In reference to a remark of Mr. Lunn's in his article "On the Voice," in our number for August 26, we are requested by Dr. Prosser James to say that the words quoted by Mr. Lunn formed part of the record of a case selected for publication in the "Reports on Diseases of the Throat," and that the opinion expressed was not endorsed in the report, but simply reproduced.

Dr. P. J. would have noticed this earlier, but having only lately returned from the Continent, had not seen our journal during August and September.

MEDICAL SOCIETY OF LONDON.—The opening of the winter session of this society, announced in our last for the 9th inst., should read the 19th.

FOTHERGILLIAN GOLD MEDAL.—The Medical Society of London announces the following subjects for competition in March, 1875, for this valuable prize: "The Diseases of the Testicle and the Spermatheca Cord." The subject for March, 1876, is, "On Cataract and its Treatment." Particulars of the competition will be found in our advertising columns.

CHEAP BOARDING FOR HOUSE-SURGEONS.—The authorities of the Carmarthen Infirmary advertise for a resident medical officer at a salary £100 per annum, with board, lodgings, &c., or £120 without board. Truly the *cuisine* and its appendages must be of a luxurious character when the medical officer's portion is estimated at a little over one shilling per diem.

HONEST ADULTERATION.—Henceforth no one need buy butter, inasmuch as Messrs. Dordron and Co., of 25 Finsbury Place, London, advertise to supply "butterine, a most delicate and nutritious article of food, superior to Dorset and Dutch butter." These public benefactors go on to state that "its use will effect an immense saving; butterine, being composed of suet and milk, is half the price of butter." At least this announcement contains an honest confession. If the public like "bread and suet" at half the price of bread and butter, Messrs. Dordron and Co. have conceived the method of preparing it to perfection, and so disguising the taste that only an expert could tell it from fresh

butter prepared from the milk of the cow. Here, then, is a rare chance for buttermen: Buy "butterine" at half price, rub it against a churn, and sell it as superior fresh at fifty per cent. profit; Messrs. Dordron and Co. have kindly paved the way.

## VACANCIES.

Mohill Union, Ryann Dispensary District. Medical Officer. Salary £120 per annum, exclusive of fees. (See Advt.)

St. Marylebone, London. Medical Officer for the Christ Church District. Salary, £230 per annum. Application to be made to the Clerk, at the Union Office.

Parish of Lambeth, Surrey. Resident Medical Officer and Dispenser for the parish Infirmary. Salary, £100, with board, &c. Candidates should address the Clerk to the Guardians, at the Union Offices.

Ramsgate Dispensary. Resident Medical Officer. Salary, £100, with furnished apartments. Applications to the Secretary.

Tunbridge Wells Dispensary. House Surgeon. Salary, £100 per annum, with board and lodgings. Applications to the Secretary.

University College, London. Professorship of Comparative Anatomy and Zoology. Full information of Mr. Robson, at the College.

North Staffs Infirmary, Harts-hill. Junior Resident Medical Officer, wife to act as superintendent of nurses. Commencing salary at £250. Board, &c., provided. Applications to the Secretary.

Bridgeforth Infirmary. House Surgeon. Salary, £100. Testimonials to be forwarded to the Hon. Sec.

King's College, London. Professorship of Physiology. For particulars apply to Mr. Cunningham, the Secretary.

Metropolitan Free Hospital. Assistant Physician. Honorary.

Dumfries Infirmary. House Surgeon. Salary, £30 per annum, with board and residence. Apply to the Treasurer.

Jersey General Dispensary. Resident Visiting and Dispensing Medical Officer. Salary, £120 per annum. Apply to the Rev. P. Le Feuvre, Jersey.

Carmarthen Infirmary. Resident Medical Officer. Salary, £100 per annum, with board and lodgings. Address Mr. Howells, King Street, Carmarthen.

## APPOINTMENTS.

ADDERLEY, J., M.D., Resident Medical Officer and Apothecary to the Cork Fever Hospital.

ANDERSON, J. W., M.D., Assistant Physician to the Royal Infirmary Dispensary, Glasgow.

ATKINS, G. P., L.R.C.P. Ed., L.R.C.S.E., Resident Medical Officer to the Fever Hospital, Cork Street, Dublin.

BEATSON, G. T., M.B., C.M., L.R.C.S. Ed., Senior House Surgeon to the Newcastle-on-Tyne Infirmary.

BELLIS, E., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer of Health for the District of Much-Woolton, near Liverpool.

BEVERIDGE, R., M.B., L.R.C.S. Ed., an Examiner for Graduation in Medicine at the University of Aberdeen.

CALDWELL, S., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer, &c., for the Virginia Dispensary District of the Oldcastle Union, co. Meath.

CAMERON, J., M.B., C.M., Medical Superintendent to the Argyll and Bute District Lunatic Asylum, Lochgilphead.

DEAN, T., M.D., M.R.C.S.E., Medical Officer of Health for the Burnley Rural Sanitary District.

GAMGEE, A., M.D., F.R.C.P. Ed., Assistant Physician to the Manchester General Hospital and Dispensary for Sick Children.

GILL, H. C., M.R.C.S.E., Medical Superintendent of the York Lunatic Asylum, Bootham, York.

GREENSILL, E. S., M.R.C.S.E., House Surgeon to the Royal United Hospital, Bath.

HAMILTON, F. G., M.R.C.S.E., a House Surgeon to the Queen's Hospital, Birmingham.

HOURIGAN, Dr. W. P., Medical Attendant to the Royal Irish Constabulary, Tullaroan, co. Kilkenny.

MACKENZIE, L., L.R.C.P. L., M.R.C.S.E., Resident Medical Officer to the London Hospital.

MAOER, R. J., L.R.C.S. Ed., Medical Officer to the Workhouse and Fever Hospital of the Kilkenny Union, and a Medical Officer, &c., for the Kilkenny Dispensary District.

MURPHY, J., M.B., Junior House Surgeon to the Sunderland Infirmary.

NORMAN, C., L.K.Q.C.P.I., L.R.C.S.I., an Assistant Medical Officer to the East Dispensary, Liverpool.

O'FARRELL, N. S., M.B., L.R.C.S.I., Medical Officer, &c., for the Woodstown Dispensary District of the Waterford Union.

OGSTON, A., M.D., an Examiner for Graduation in Medicine at the University of Aberdeen.

SMITH-SHAND, J. W. F., M.D., L.R.C.S. Ed., an Examiner for Graduation in Medicine at the University of Aberdeen.

## Marriages.

SALTER-HAYCOCK.—On the 7th inst., at St. Stephen's, Paddington, James Salter, M.B., F.R.S., to Fanny, youngest daughter of the late Edward Haycock, Esq., of The Priory, Shrewsbury.

MORISON-HOGG.—On the 7th inst., at St. George's, Hanover Square, John Morison, M.D., of St. Helier's, Jersey, to Maud, eldest daughter of Robert Hogg, LL.D., of St. George's Road, S.W.

## Deaths.

BLACKSTONE.—On the 1st October, J. Blackstone, M.R.C.S.E., of Gloucester Road, Regent's Park, London, aged 78.

KIRKWOOD.—On the 7th October, at Ayr Villa, Malda Vale, London, after a long illness, John Templeton Kirkwood, M.D., M.R.C.S., in the 63rd year of his age.

THOMPSON.—On the 21st September, Robt. Thompson, M.R.C.S.E., of Theatre Street, Norwich, aged 63.

### ON THE SCIENTIFIC AND EMPIRICAL INVESTIGATION OF EPILEPSIES. (a)

By J. HUGHLINGS JACKSON, M.D., F.R.C.P.,  
Physician to the Hospital for the Epileptic and Paralysed, and to the London Hospital.

#### LECTURE I.

#### PART II.—SUMMARY.

I SHALL be obliged, in carrying out the Method above stated, to consider at length many subjects usually considered apart from epilepsy. I will here give a sketch of some of the more important of them. I do so chiefly because what has to come in the early chapters will involve anticipations of what has to be proved in later ones.

Before I go further I have certain obligations to acknowledge. I am under very heavy obligations to Herbert Spencer. I shall acknowledge these obligations in detail in later chapters. It will, however, be apparent in almost every part of the latter half of the present chapter that I am greatly indebted to him. Let me at once give a quotation from his "Psychology" with regard to Evolution of nervous centres, a subject on which I have much to say: "In the functions of the successively higher vertebrate centres, reaching their climax in the human being, we see well exemplified the law of development of functions in general."—"First Principles," p. ii., § 142.) "This progress from co-ordinations that are small and simple to those that are larger and compound, and to those that are still larger and doubly compound, is one of the best instances of that progressive integration of motions simultaneously becoming more heterogeneous and more definite which characterises Evolution under all its forms."—"Principles of Psychology," vol. i., p. 67.)

I must mention very prominently Laycock's doctrine of the Reflex Function of the Brain. The following is a

(a) This and subsequent chapters to be published in this journal are the introductory chapters of a forthcoming work on Epilepsy.

quotation from an article written by him thirty years ago. The first sentence of the quotation refers to a still earlier exposition of the doctrine in his treatise on the "Nervous Diseases of Women." This book was published in 1840, and contains a chapter (p. 105) headed "The Instinctive Actions in Relation to Consciousness: the Brain subject to the Laws of Reflex Action."

"Four years have elapsed since I published my opinion, supported by such arguments as I could then state, that the brain, although the organ of consciousness, is subject to the laws of reflex action, and that, in this respect, it does not differ from the other ganglia of the nervous system. I was led to this opinion by the general principle that the ganglia within the cranium, being a continuation of the spinal cord, must necessarily be regulated, as to their reaction on external agencies, by laws identical with those governing the spinal ganglia, and their analogues in the lower animals. And I was confirmed in this opinion by finding, after the investigation and collocation of known facts, that observations and arguments like those satisfactorily adduced in proof of the existence of the reflex function of the spinal ganglia, may be brought forward in proof that the cerebral ganglia have similar endowments. In the present paper I propose to give these proofs connectedly."—(*British and Foreign Medical Review*, vol. xix., January, 1845, p. 298.)

I have italicised some parts of this quotation which state clearly a principle I shall re-state from a different standpoint when speaking of the relations of Psychology to the Anatomy and Physiology of the Nervous System.

It is scarcely necessary to point out that, like all other writers on Epilepsy, I am in debt to Brown-Séquard.

To Dr. Ferrier I am very specially indebted. I shall have many opportunities of acknowledging my very great obligations to him. His well-known researches, and those of Hitzig to which he refers, are of inestimable value for clinical medicine, as well as for physiology.

To Professor Bain I owe much. From him I derived the notion that the anatomical substrata of Words are motor (articulatory) processes. (This, I must mention, is a much more limited view than he takes.) This hypothesis has been of very great importance to me, not only specially because it gives the best anatomico-physiological

explanation of the phenomena of Aphasia when all varieties of this affection are taken into consideration, but because it helped me very much in endeavouring to show that the "organ of mind" contains processes representing movements, and that, therefore, there was nothing unreasonable in supposing that excessive discharge of convulsions should produce that clotted mass of movements which we call spasm. (a)

Not less are my obligations to Mr. Lewes. I shall have to refer to his writings in many parts of this book.

I now proceed to brief anticipatory statements of some of the topics to be discussed at length in later chapters.

The method of studying cases as departures from health obliges me to compare and contrast the effects of "destroying lesions" with those of "discharging lesions." I have incidentally illustrated this by the contrast and the comparison of hemiplegia and hemispasm for another purpose. I will now give another example. When I speak of epileptiform aphasia I must speak of aphasia caused by a permanent gross lesion. For, after, as well as during, certain epileptiform seizures, we find temporary defects of speech like those more permanent ones which so often result from embolism or thrombosis, or from clot. Sometimes there is hemiplegia with it—epileptic hemiplegia of Dr. Todd. It is unreasonable to study a suddenly occurring and transitory symptom without comparing it with what we have learned of the same symptom when permanent, which latter we can study with any degree of minuteness, and at our leisure.

Another matter closely connected with the subject just spoken of is that it is absolutely necessary to consider convulsion and other paroxysmal symptoms as "experiments (b) made by disease" which reveal the localisation of processes for different groupings of movements and impressions in different parts of the cerebral hemispheres. This is, so far as I know, quite unfamiliar, and, therefore, has an air of unreality. It requires a vast amount of time to observe cases of convulsion minutely enough for this purpose. Nothing in our clinical work demands so much patience. The results of the experiments of Fritsch, Hitzig, and Ferrier are infinitely more precise than those of the "experiments of disease," but the latter are nevertheless, I assert again, absolutely necessary, as they are the only experiments on the brain which can be observed for the localisation of movements in the case of Man. For this purpose, since "destroying lesions" of much of the cerebral hemisphere produce no obvious or striking symptoms, we are obliged to study the effects of "discharging lesions" in these parts.

Epilepsy, like Aphasia, has been studied with a Psychological habit of mind, and, as I think this way of studying such a disease is unfruitful, I have to point out in detail the vast difference there is betwixt Psychology and the Anatomy and Physiology of the Nervous System. The confusion of the two, as I believe, is really one of the great hindrances to the acceptance of the view that the convulsions (parts of the "organ of mind") represent movements. The notion seems to be that the "organ of mind" being for "ideation," cannot contain processes representing movements.

Admitting, as the whole educated world now does, that all mental states have parallel physical states, I think our direct concern as physiologists and physicians is with the latter only. Hence, I should not use such expressions as that hemiplegia is "owing to loss of volition," or that a person did not speak because he had lost the "memory of words." These are really little better than Verbal propositions. I willingly plead guilty to having

(a) I ought to mention that Dr. Bastian, a physician whose opinion on any such subject deserves the greatest respect, has vigorously and very ably combated Bain's opinion, and, at the same time, my explanation of the phenomena of Aphasia founded on it.—(*Med. Chir. Rev.*, January, 1869.)

(b) See "On Localisation of Movements in the Brain," *Lancet*, January 13, 1873, *et. seq.* I shall shortly republish this paper in a separate form, and also a valuable paper by Dr. Gowers, "Cases of Convulsion from Organic Brain Disease"—(*Brit. Med. Jour.*, September 26, 1874.)

formerly used similar phrases open to the same criticism. I should also in an investigation like this, when possible, avoid such expressions as "centres of ideation," "emotional centres," &c., not because I dispute their correctness, but because our concern, as physicians, is with the anatomical substrata of ideas and emotions. Besides, the expressions objected to refer only to the material basis of mind. To give a material explanation of mental states, admitting its correctness so far as it goes, is not to give an anatomical explanation. Again, to say that the substrata of mind are made up of arrangements of cells and fibres or centres of cells and fibres, is to make a statement which is not disputed by educated people now-a-days, but it is only a statement in morphology; or rather, such expressions as "centres of ideation" are mixtures of Morphological and Psychological terms. They contain nothing anatomical or physiological. The anatomical substrata of ideas (of the more important, evidently) are sensori-motor processes. The whole of the central nervous system, cerebral hemisphere, spinal cord, &c., is made up of processes of differing degrees of complexity representing impressions and movements. There are, so far as I can judge, no other "materials" of which the "organ of mind" can be made up. As the quotation from Spence implies, the very highest of all nervous centres are but complex rearrangements of lower centres, and these of still lower centres unto the lowest, which last directly represent impression and movements.

Perhaps one criticism on the above will be that I am confounding "mental" states with "physical states." A reader may perhaps suppose that I imagine processes for impressions and movements to become in the highest centres so fine that they "fine away" into mental states. I do not. To show what I really think, let me quote the words of Herbert Spencer:—

"Though accumulated observations and experiments have led us by a very indirect series of inferences to the belief that mind and nervous action are the subjective and objective phases of the same thing, we remain utterly incapable of seeing and even of imagining, how the two are related."—(Spencer, "Prin. of Psy.," vol. i, p. 140.) Elsewhere Mr. Spencer writes:—

"See, then, our predicament. We can think of Matter only in terms of Mind. We can think of Mind only in terms of Matter. When we have pushed our explorations of the first to the uttermost limit, we are referred to the second for a final answer; and when we have got the final answer of the second, we are referred back to the first for an interpretation of it. We find the value of  $x$  in terms of  $y$ ; then we find the value of  $y$  in terms of  $x$ ; and so on we may continue for ever without coming nearer to a solution."—("Prin. of Psy.," § 272.)

To show my feeling on the matter, I will remark that I consider the confusion I have spoken of is really fostered by such classifications as those of aphasia which put together "ataxy of articulation" (physiological phraseology) and "loss of memory for words" (psychological phraseology) and imply nothing of the nature of the anatomical substrata of words.

How from or during the energising of sensori-motor processes or of the highest of them, there arise mental states, is not our concern, not our direct concern at any rate, in such investigations as the present. Yet it is of no importance, for this investigation, what view of the connection of mind and matter we take. If any reader supposes mind to be a function of matter (thought, let us say a secretion of brain), I should simply say to him that one does not concern oneself with that "function" in an anatomical and physiological inquiry, but with another function—viz., the energising of cells and fibres representing peripheral impressions and adjusted movements.

I make these last remarks because I think some people have the notion that to take a materialistic view is to take a "practical" view. But, as above stated, a merely material view is not an anatomical one. In the sake of argument that it is perfectly correct, it goes, it has to go a stage further.

shall try to show later that under this supposed "practical" guise work has been done on the old-fashioned system. We judge people not by the names they use, but by their method. The old-fashioned method spoke of an immaterial mind. The very same method in a new dress still speaks of a brain as if it were a "solid mind" governing and acting on the body, and not as if it were simply the most developed part of the nervous system "regulated by laws identical with those governing the spinal ganglia" (*Laycock* quoted).

The first half of the compound word "sensori-motor" is not free from objection. The word "sensation" is often confusedly applied both to a physical state and to the mental state which occurs along with it (see *Mill's Logic*, vol. ii., p. 43); for example, it is used for colour (mental state) and for the molecular disturbances in the "optic nervous system" which occur therein whilst that mental state exists. It is used for pain, and for the associated disturbances in afferent nerves and centres. I think this confused use of the word leads to many misunderstandings. It makes it fallaciously easy to understand how it is that we have mental states from (or during) the energising of Afferent nerves and centres, whilst no thought is given to the possibility that mental states arise during energising of Efferent nerves and their centres. To give an example, it makes it seem easy to understand that energising of nervous processes representing retinal impressions should give us ideas of objects, whilst it leads to difficulty in accepting the opinion that energising of processes representing articulatory movements should give us ideas of words. The real fact is, that in neither case can we tell why during energising of cells and fibres we have ideas. The difficulty is just the same in the two cases, for mental states arise from or during molecular movements in nerve cells and fibres, and they arise, I submit, during molecular movements in nerve cells and fibres representing movements as well as during molecular movements in those representing impressions. "Sensations" in the sense of "mental states," arise, I submit, during energising of motor as well as of "sensory" nerve processes—with the "out-going" as well as with the "in-going" current. I should not dwell on this were it not that the distinction insisted on is of very direct importance. For example, I have to show that vertigo is essentially a motor symptom, and that the "sensation" of vertigo is no proof that vertigo is fundamentally an affair of "sensory" (afferent) nerves or centres.

Although I have, for convenience, spoken separately of afferent and efferent processes, and, if I may so speak of afferent and efferent centres, both are concerned together on the anatomical and physiological side of "ideation." The former are evidently concerned in acquiring ideas of the dynamical or secondary qualities of objects, the latter in acquiring ideas of the statical or primary. For example, in actually seeing objects, there is a strong discharge from periphery (retina) to centre, and from centre to periphery (ocular muscles). (a) There is not sensory action only, nor motory action only; there is sensori-motor action. There is a similar process in having the ideas again. The faint and central discharges which occur in thinking of objects (recollecting, being conscious of, having an idea of, &c.) will be of nervous processes which are representatives of both (b) impressions and movements. For, in thinking of objects,

(a) "The qualities of things admitted on all hands to be qualities of the external or object world—called the Primary Qualities—Resistance and Extension—are modes of our muscular energies; the qualities that do not of themselves suggest externality or objectivity, the Secondary qualities as Heat, Colour, &c., are our passive sensibilities, and do not contain muscular energy."—(Note by Bain, p. 5, vol. i., of James Mill's "Analysis of the Human Mind.")

The ocular movements spoken of in the text are, strictly speaking, symbols of the tactual and locomotor movements that give us our ideas of the primary qualities.

(b) This statement embodies, I believe, Spencer's theory of the physical process which occurs during recollection. (See "Prin. Psych.," vol. i., p. 124, and p. 456.)

there is not only a Representation of surface (colour), but also of size and figure. In fact, the discharge will be of the very same series of nervous processes in Presentation and Representation; in the latter the discharge is slight, and is limited to the centre, whilst in the former it is strong, and reaches from periphery to centre, and from centre to periphery. We shall see that in accordance with these views there occurs from the epileptic, which is not only a strong but an excessive discharge of "centres for ideas," brutal development of the two elements—crude impressions (clouds of colour appearing to the patient, for example) and that clotted mass of movements we call spasm.

As will be inferred, I adopt Bain's views on the "out-going" current. The facts of cases of vertigo, many ocular symptoms, but most strikingly the production of "ideal" movements by faradising stumps have led me to accept his opinion. I have in a former paper (in the 3rd vol. of the "West Riding Asylum Reports," (a) p. 191) spoken of the proof which such cases give that central excitations of processes representing movement suffice in internal speech and other mental operations. Remarks like these are foreign to the subject of epilepsy as that disease is usually studied, but not foreign to my view of it. For, as above stated, I believe epileptic paroxysms result from discharges of parts of the organ of mind, from discharge of parts containing anatomical substrata of ideas, into which substrata the element movement necessarily enters.

In order to obtain a realistic view of the symptom, Loss of Consciousness, I have to speak in detail of the Evolution of the higher nervous centres out of the lower. All nervous centres represent or re-represent impressions and movements. The highest centres are those which form the anatomical substrata of consciousness, and they differ from the lower centres in compound degree only. They represent over again, but in more numerous combinations, in greater complexity, speciality, and multiplicity of associations, the very same impressions and movements which the lower, and through them the lowest, centres represent. They represent the whole Organism. They represent not only the impressions of the five senses, and the movements ordinarily so-called, but also organic or systemic sensations (Bain and Lewes) and movements of the heart, arteries, intestines, &c. "The seat of consciousness is that nervous centre to which, mediately or immediately, the most heterogeneous impressions are brought." (b) The statement is not of the most numerous impressions, but most heterogeneous. To the seat or seats of consciousness, impressions of all orders are brought, and from it issue motor impulses of all orders.

Let us see how the paroxysms of certain cases of epilepsy corroborate this view—that the highest of the highest nervous centres re-represent the whole of the body. The cases I mean are those in which the symptom loss of consciousness is the first event in the seizure (cases without a "warning"). Now, these are the cases in which the discharge begins in the very highest centres (in the substrata of consciousness). They are the cases which commonly go by the name of true or idiopathic epilepsy. To say of a paroxysm of epilepsy that it begins with loss of consciousness is a symptomatic expression; to say that the discharge begins in the very highest processes is the anatomico-physiological expression corresponding to it.

In those cases of epilepsy in which loss of consciousness is the first event in the paroxysm, the convulsion is universal, the two sides of the body are more nearly equally and more nearly contemporaneously convulsed; it is in

(a) I tried to show two things—(1) that energising of processes representing movements is a factor in the physical side of ideation (as, for example, in ideas of size and figure), and (2) that nascent excitation (excitation limited to the centre), or otherwise expressed, a "motor impulse," suffices in memory, &c. For in the cases spoken of, notably in faradising stumps, we have ideas from excitation of motor centres when the current developed is physically debarred from reaching the muscles.—("On Faradising Stumps." See the masterly work of Weir Mitchell on "Injuries of Nerves.")

(b) Spencer, "Psychology," vol. i., p. 105.

these cases that there is, at the very first, much pallor of the face. I think these cases agree with the conclusion that the sensori-motor processes which form the anatomical substrata of consciousness are evolved out of, re-represent, and so to speak, potentially contain, all other (lower) series of sensori-motor processes. (a) For a discharge beginning in these highest processes affects the whole body quickly, and affects the whole very nearly at the same time.

This realistic method of treating the symptom, "loss of consciousness," is a matter of the utmost importance. We can, on this method, study the "mental" as well as the "physical" symptoms of epilepsy anatomically and physiologically, and free from that psychological bias which makes the symptom loss, or trouble of consciousness, an isolated phenomenon, with no relations to other nervous symptoms.

Here, reverting to a former topic, I may again draw attention to the importance of studying epilepsy by the aid of far simpler cases of nervous disease. I could not at an earlier stage give this illustration. From the facts of cases of cerebral hæmorrhage, cerebral tumour, &c., I have long since drawn the conclusion that the convulsions of the cerebral hemisphere represent not only ordinary movements and impressions, but the whole of the "vital" processes. In a paper in the *Medical Mirror*, Oct., 1869, I write, except for a few verbal alterations, as follows: "We have now, then, to add to the constitution of the Units of the Cerebrum nerve fibres to the heart, vessels, and viscera, or rather probably to regions of the sympathetic system from which these parts are supplied. The inference we have now arrived at is that the units of the cerebral hemisphere (in the region of the corpus striatum, at least) represent potentially the whole processes of the body. If this be so we can understand how it happens that in cases of epilepsy (beginning by loss of consciousness, i.e., beginning in the highest nervous processes), besides obvious convulsion, we have premonitory shivering, pallor of face, and increased flow of saliva, and in some cases vomiting. Thus, too, we see how it is that emotional manifestations accompany intellectual phenomena. Emotional phenomena are wide and yet temporary bodily states, and we have seen that the heart, arteries, and viscera, as well as the large muscles of the body, are represented in the units of the cerebrum."

I must consider at some length another general principle—the principle of Compensation in nervous organs. This clears the superficial paradox stated in a former paragraph—viz., that destruction of parts in a certain region of the cerebrum produces no obvious, or striking symptoms, notwithstanding that strong discharge of those parts produces exceeding violence of movement (convulsion).

The movements represented in the destroyed part are represented, although in somewhat different order, in neighbouring parts (the compensation is never absolute). Taken with the principle of evolution, the principle of compensation accounts, I consider, for the fact that fits, declared to be like the epileptic fits of man (and which I believe result from discharges of parts of the cerebrum), can result in lower animals from discharge of the pons varolii and medulla oblongata—can result, that is, when the cerebrum is taken away. For I shall try to show that, as I have already in principle said, when speaking of loss of consciousness, the cerebral hemisphere re-represents the very same external parts which the pons varolii, and all other lower centres represent, but more specially, in greater complexity, &c. In man re-representation or evolution is carried many stages further than in the brute: Man has the large cerebral hemisphere; the brute the large pons and medulla.

There is also to be considered the principle of Dissolution. As in evolution the development is from the general to the special, so in the opposite process of dissolution the

undevelopment is from the special to the general. Using psychological terms, and taking particular cases, we may illustrate by saying that the Insane Patient is one who is reduced to a more automatic condition of Mind, the Aphasie to a more automatic condition of Language, and the Hemiplegic Man to a more automatic condition of Voluntary Movement. If the reader bears in mind what was implicitly stated of Evolution when the symptom Loss of Consciousness was considered (that there is a continuous transition from the lowest centres concerned in the most general or most automatic physical actions, through intermediate centres up to the highest centres concerned in the most special or most voluntary actions, that is to the anatomical substrata of consciousness) he will see that the following statements on the conditions of the Insane, the Aphasie and the Hemiplegic man, are, although from a different standpoint, to the very same effect as the statements already made—that they are "reduced," &c. The insane man has lost the use of, or of some of, the most special of all nervous processes whatsoever; he has, indeed, defect of consciousness. The aphasic man has lost the most special processes of the language series; the hemiplegic man the most special processes for movement.

This principle will have to be expounded at length, because it enables us to understand the duplex condition in acute attacks of insanity occurring with Epilepsy (epileptic mania) and also in Insanity ordinarily so-called. I will speak briefly on it now. First let us recapitulate. The principle of evolution is that the higher centres are evolved out of the lower. The highest centres (the anatomical substrata of consciousness) are, as it were, the climax of the evolution, and re-represent all lower centres. In other words they represent the whole Organism (Subject). It is only another mode of stating the same thing to say that they are the processes by which the organism as a whole, is adjusted to its Environment (Object). There are after certain epileptic attacks Reductions to more general adjustments, corresponding to lower ranges of evolution—we may say there are Lowerings of Adjustment, owing to different depths of dissolution beginning in the highest centres.

This last way of stating the process of Dissolution is most convenient for our purpose. I will restate it with details. Considering the very highest of all nervous processes as those concerned in the most special adjustments of the organism as a whole to its environment (see quotation from Spencer in next foot-note), and considering that these processes are evolved out of lower series of processes which represent more general adjustments, and these again out of still lower series representing adjustments still more general, and so on to the lowest series of nervous processes in the body—we can, I think, by taking note of the experiments of disease, show stages of lowering of adjustment as consequences of different depths of Dissolution of the higher centres. Such lowering of adjustment is indeed but another aspect of Dissolution, and is equivalent to saying that the organism is reduced to a more automatic condition. On this way of putting it, it matters not whether consciousness is displayed or not during the play of the more general adjustments. The question is—"How is the Organism adjusted to its Environment?" Let us now see how these principles apply to epileptic mania and to other conditions following severe epileptic discharges.

As before said, an epileptic maniac is one who has been reduced to a more automatic condition of mind. He is so reduced by loss of use of (exhaustion of) the highest centres, consequent on a strong nervous discharge beginning in them. But we shall see that there are, after different degrees of epileptic discharges beginning in the highest centres, all degrees of dissolution, or otherwise put all degrees of lowering of adjustment (a) of the organism to

(a) It is most insignificant, whatever the explanation may be, that there are slight cases (*petit mal*) in which, with merely transient loss of consciousness, there is deep pallor of the face, and a slight wave of universal movement. In such cases there is often a warning by a feeling mostly very disagreeable but not ordinary pain at the epigastrium. This feeling is, I believe, a development of Systemic sensations.

(a) "For since all modes of consciousness can be nothing else than incidents of the correspondence between the organism and its environment, they must all be different sides of, or different phases of, the co-ordinated groups of changes whereby internal relations are adjusted to external relations."—(Spencer's "Psychology," No 25, p. 496.)

its environment. Starting from a condition which is subjectively only slight confusion of thought, we can trace all gradations to deepest coma, in which last there remains only action, and that imperfect, of some of the most automatic of all processes, respiration and circulation. There is indeed sometimes a loss of all adjustment, which is death.

The condition of things in Insanity differs only in degree from that in epileptic mania. The ordinary insane patient has *defect* of consciousness, analogous to the *loss* of consciousness of the epileptic maniac; the "symptoms" of insanity are due to quasi-healthy actions of more automatic processes, as are also those of the epileptic maniac.

Two things which should, I think, be considered separately, are often considered together under Heredity. I have, then, to speak in two places of heredity. I have to show under Pathology that there is hereditary transmission (1) of a tendency to diseases of Tissues; and in another place I have to urge that there is (2) transmission of imperfect Organs. The "facts" of these hereditary transmissions are not, I consider, evidence that there is inherited a tendency to particular *diseases* or *symptoms*, such as chorea, epilepsy, insanity, &c. Let me show one kind of confusion. (I here speak of the "genuine epilepsy" of authorities.) If in an epileptic patient's family hemiplegia had been common, it would be no evidence whatever that a tendency to epilepsy was inherited (as a *nervous* disease I mean, of course), for the very simple reason that hemiplegia itself is not, strictly speaking, a nervous symptom. In the vast majority of cases it is an *arterial* affair. Hemiplegia mostly occurs because an artery breaks (hæmorrhage), or because an artery is blocked up (softening from thrombosis). Yet it is common to find such "facts" brought forward as proof of inheritance of *nervous* diseases, or of a tendency to them.

The Neuroses in particular are mostly supposed to be hereditary directly, or by substitution. For the present I draw attention to the significant fact that *the pathology of these diseases, which are supposed to be pre-eminently hereditary, is, according to most physicians, unknown.* Under pathology I shall, I hope, show that in nearly all cases of "nervous" diseases or symptoms of which the pathology is known, morbid anatomy declares that the changes begin in non-nervous tissues. I confess that my impression is that this will be found to be the case with epilepsy and the allied neuroses. Indeed, I think there is already, to say the least, a strong case for the inference that one of them, chorea, is very often an arterial affair; the discharging nerve tissue in this disease I believe becomes unstable from hyperæmia, a result of plugging of arteries.

Heredity with regard to the transmission of imperfect Organs has to be considered in order to help to make clearer the nature of the symptoms of Epileptic Mania, and other forms of insanity. A man does not, according to my hypothesis, inherit insanity of any kind. The man whose insanity is said to have been transmitted is, I think a person who inherits an imperfect nervous system, not imperfect in its tissues, but in relative development of its higher and lower centres. First, the higher, and metaphorically speaking, *controlling centres* are in him imperfectly developed, that is to say, psychologically speaking, the latest faculties acquired by the race are in him ill-developed. Secondly, the lower centres and corresponding lower faculties are in comparison over-developed. (a)

Such a man is more liable than another man to become insane, but not because he more than another man has any

(a) I do not mean by "higher" faculties simply mind generally, or by "lower" the "passions and instincts." There are all gradations from instinctive actions, or even from the lowest and simplest reflex actions to the highest processes concerned in reasoning (see Spencer *passim*). Nor is the expression "emotional" limited, as it often is, to the common and superficial emotions. The highest faculties (those last acquired by the race) are the power of Abstract Reasoning (Intellectual) and the sentiment of Justice (Emotional)—(Spencer). In cases of commencing disease of the brain, loss of power of connected thought on difficult and complex matters, with peevishness and selfishness, are owing to defects in these two highest faculties. These defects, when in slight degrees, are popularly called "alterations" of the disposition.

tendency to *disease of the tissues of the brain* (connective, arterial, or nervous), but because either any actual disease of the tissues of his brain, or general severe ill-health, nay, even misery, &c., would very easily impair, or put entirely out of use, the highest (controlling) nerve processes. On the principle of dissolution the highest of his nervous processes are those which will fail first, from causes affecting the whole brain. He is more easily than another man rendered insane by epileptic fits, because he can bear little damage of any sort to the highest parts of his nervous system. He is sometimes a man who would be easily excited ("maddened," his friends may say) by drink. (See Griesinger, "Syd. Soc. Trans.")

I do not believe that there is an insane neurosis interchangeable with epilepsy, chorea, or neuralgia. Insanity and such diseases as epilepsy and chorea are not fairly comparable. The *active* symptoms of insanity are not directly due to the *disease* of the brain or of any other part of the nervous system, as the symptoms chorea, convulsion, and spasm, are. The "symptoms" of insanity are due to action of lower centres of the brain, which centres are healthy except for exaggerated action, consequent on loss or defect of the highest and controlling centres, the parts really *diseased*. The insane man is reduced to a more automatic condition of mind by loss of or defect in these highest and controlling centres, or, as we have otherwise expressed it, his adjustment is lowered. In the acute insanity of epileptic mania the "disease" is that the highest centres are temporarily and suddenly paralysed by a strong nervous discharge; the mania, like the insanity, is owing to uncontrolled action of lower and more automatic (a) centres, which centres are not diseased.

I do not mean to imply that I can prove all these points satisfactorily. In particular, at present I have no satisfactory answer to the objection which is sure to be brought, viz., that epilepsy artificially induced in guinea-pigs (Brown-Séquard) is hereditary.

It will be granted that it is very difficult to show that such different lines of thought as those mentioned above harmonise. Evidently in writing the earlier chapters of this book I must anticipate conclusions to be reached in later ones. I have endeavoured to render my method less difficult to the reader by a free use of foot-notes.

Such a way of handling a subject is, however, not favourable for clearness of exposition. It is far from easy to make plain the relations of things, some of which have been almost universally considered separately from epilepsy. I have therefore for several years delayed the execution of this work; but the recent brilliant researches

(a) As will be inferred, I accept Laycock's doctrine on the Reflex Function of the Brain (*vide supra*). I accept also a principle formulated by Dr. Anstie, some years ago, that increased action of lower centres is due to loss of control by the higher, or, as I suppose we may say now-a-days, to lack of inhibition (see his *Stimulants and Narcotics passim*). The great differences betwixt epileptic mania and insanity ordinarily so-called are, I think, due to differences in the suddenness with which the highest processes are put wholly or partially *hors de combat*.

The following extract from the *Medical Times and Gazette*, July 9, 1873, referring to Heredity, may help to make what I have said in the text clearer:—

"The facts of 'transmission of disease' are not denied, but a very different interpretation of them is suggested. There is now attending the out-patient room a boy who is manifestly the subject of congenital syphilis, and whose mind has failed several months. One sign of mental failure has been a magpie-like hiding of tools. It would be, Dr. Hughlings Jackson thinks, unmethodical to call this lad's mental condition 'Syphilitic Insanity'—obviously grotesque if, going into details, we should say that hiding his fellow-workmen's tools was a syphilitic symptom. The boy's father died insane in Colney Hatch. This boy has received as his father's share in his development not only a syphilitic taint, but a nervous system, the higher division of which is easily 'reduced.' It so happens that the reducing agent has been in all probability syphilitic disease. The inheritance was not of insanity, but of a brain ready to fall on comparatively slight provocation of any kind—one probably easily upset by drink or excitement (easily excited, rather). No doubt anything which involved even slight damage to the cerebrum would in such a brain have 'caused' insanity, from so-called 'alteration' of disposition up to insanity as the term is commonly used."

of Ferrier encourage me in the belief that a connected account of the work I have done on epilepsies may be acceptable. For he mentions that he undertook his experiments partly with the object of putting to "experimental proof" the views I have put forward on epilepsy. (a)

The value of Ferrier's researches as contributions to the anatomy and physiology of the nervous system could scarcely be overrated. But very naturally to me, a physician, their greatest value seems to be for the help they afford in the methodical investigation of that most inhuman of all diseases, epilepsy. It is a matter of great satisfaction to me to find that my views have passed well through the ordeal. Ferrier, speaking of his experiments, writes:—

"The pathology of epileptiform convulsions, chorea, and epileptic hemiplegia, receive much light from the foregoing experiments. I regard them as an experimental confirmation of the views expressed by Dr. Hughlings Jackson. They are, as it were, an artificial reproduction of the clinical experiments performed by disease, and the conclusions which Dr. Jackson has arrived at from his observations of disease are in all essential particulars confirmed by the above experiments." (*Op. cit.*, p. 85.)

In spite of the encouragement I have received from these researches, I feel that it requires more skill than I possess to make my subject clear to those who have long worked at epilepsy from a totally different point of view.

## A Course of Lectures

ON THE

### NATURE AND TREATMENT OF DEFORMITIES OF THE HUMAN BODY,

DELIVERED IN THE MEATH HOSPITAL, DUBLIN, BY  
LAMBERT H. ORMSBY,

Surgeon to the Hospital, and Demonstrator in the School of Surgery,  
Royal College of Surgeons in Ireland.

#### LECTURE VIII.

### DEFORMITIES AND DISTORTIONS OF THE NECK AND FACE.

*Introduction—Anterior Curvature in Cervical Region: Causes—Treatment—Wry Neck, or Torticollis: Causes—Treatment—Diseases of Cervical Vertebrae—Distortions arising from the Contraction of the Adjacent Tissues after severe Burns and Scalds: Nature and Treatment; different Operative Methods—Deformities arising from Glandular Enlargements—Deformities of the Head and Face: Causes and Treatment—Conclusion.*

DEFORMITIES in the neck and face are always of the greatest moment to the surgeon, as any deviation from the natural state is rendered so apparent to the eye of observation that every imaginable plan is adopted at times by the unhappy sufferer to cover and hide what is remarkable in their personal appearance.

I will divide, for convenience, such deformities under six heads—

- 1st. Anterior Curvature.
- 2nd. Wry Neck, or Torticollis
- 3rd. Disease of Cervical Vertebrae.
- 4th. Distortions arising from the Cicatrices of Severe Burns.
- 5th. Deformities arising from Tumours and Glandular Enlargements in the Neck.
- 6th. Deformities of the Head and Face.

#### 1. ANTERIOR CURVATURE.

*Anterior Curvature*, or, in other words, "round shoulders," is occasionally to be met with in those young people of both sexes who acquire such a position by weak and delicate constitutional tendencies, combined with a habit of keeping the head and body in one continued

attitude—for example, the over-studious, continually ing over books. In such cases the muscles in the posterior aspect of the neck are weak and flaccid, and appear to be incapable of supporting the head and keeping it in equilibrium, which by the debility becomes bent forwards, and thus the shoulders assumes a rounded and prominent appearance. I have a case under observation of a young gentleman of 12, weak, pallid, and unhealthy-looking, and considerably overgrown for his age; he has always been fond of reading, and has been most studious in his habits, and has thus acquired a most insightly stoop. In this case are to be found all the general causes of the distortion. When such a deformity exists it is quite apparent, and easily recognised, and is due to delicacy of constitution, with debility of muscles in the region, allowing of greater flexibility of vertebrae, and relaxation of the various cervical ligaments.

*Treatment.*—Prevention in all cases being better than cure is as true for this subject as it is for anything else, and when the slightest deviation or stooping tendency is observed, all reading and bending over books or desks must be entirely given up for a time. Good nourishing food must be given, tonics of all kinds administered, and all healthful out-door exercises enjoined—rowing, racket recommended, or the exceeding healthful novel game of Badminton, which necessitates the head being kept in an erect posture, and so placed to correct the deformity. Girls are recommended to use the "skipping-rope" for five or ten minutes daily—galvanism applied to the debilitated muscles; good shower-baths and shampooing occasionally; mechanical instruments are of course recommended—such as a silken band applied round the head tightly, to prevent displacement; to the back of this band on either side of the head two elastic straps are attached, which are again attached to a silken strap passing round the body beneath the arm-pits. This has a powerful effect in keeping the head in an erect position by the constant action of the elastic bands. Bigg recommends this appliance as being most useful—the old-fashioned "Back-board," so much used twenty years ago, when every young lady had to use them for some minutes daily; this has also a good effect in expanding the chest. The use of the elastic chest expander is also recommended for correcting this deformity.

#### 2. WRY NECK, OR TORTICOLLIS.

*Definition and Anatomical Characteristics.*—This consists in permanent contraction of a set of muscles of one side of the neck, which causes it to be drawn permanently to one side, and the head undergoes a series of changes as regards position: 1st. It is drawn downwards to the contracted side in close proximity to the shoulder; 2nd. The face is turned to the opposite side, the eyes and curves of the lips are drawn down; 3rd. We find well-marked rotation in an advanced case of wry neck. All these stages have taken place, and the person thus affected presents a very droll and awkward-looking appearance, particularly when the person thus affected endeavours to look at you: the features of the face are very much distorted; the causes of this distortion frequently depend on structural shortening or permanent contraction of the sterno-cleido-mastoid muscle of one side with corresponding relaxation of the muscles on the opposite side; the scalenus with trapezius muscles are also occasionally at fault, and contribute by their combined action to this distortion, although in many cases you will find the sternal attachment of the sterno-cleido-mastoid very much contracted, and so tense as easily to be felt. It has also been caused by disease of the spinal accessory nerve which supplies the muscles which are frequently affected.

*Treatment* may be divided into the mechanical, operative, and constitutional treatment. Like many other cases, the treatment varies considerably, according to the causes that produced the deformity in the first instance; if all the muscles in the region participate more or less to permanent contraction, or where the muscles are debilitated and flaccid, a mechanical line of treatment may be more

(a) "Experimental Researches on Cerebral Physiology and Pathology," by David Ferrier, M.A., M.D. Edin., M.R.C.P., "West Riding Lunatic Asylum Reports," edited by Crichton Browne, M.D., F.R.C.P. Vol. iii.

useful, and attended with better results than any other method, for one form may have been a long time coming on, and in like manner the treatment must be kept up for a considerable period. Fig. 21 is an instrument that is

FIG. 21.

*Mechanical Instrument used for Wry Neck (Torticollis.)*

simple, easily applied, and is most applicable for such a case, for in many such cases the head can be brought into position with the hands, but it at once resumes its abnormal position on being left to itself. In another case, where there is merely permanent contraction of the sternal attachment of the sterno-cleido-mastoid, tenotomy is certainly the operation that should be adopted, as being simple, rapid, and efficacious; but this operation, simple as it is, ought not to be attempted without having a correct knowledge of the anatomy of the region, considering the very important blood-vessels immediately below and behind the tendon.

*How to perform the Operation.*—Place the patient in the recumbent posture. Chloroform need not be generally administered. Direct the patient to endeavour to turn the head round, and look as much as possible from the non-affected side, which will cause the contracted portion of the muscle to stand out more in relief, and thus easily to be seen and felt. Insert a small tenotome immediately behind, and at the muscle's inferior insertion, into the sternum; turn the knife with its cutting-edge forward, and the tendon is severed with the greatest ease, which is easily ascertained by feeling no further resistance given to the onward progress of the knife; a dossil of lint, a strip of plaster then applied to the puncture made, and the operation is then completed. I performed the operation only the other day on a boy of 16, and he complained of very little pain during the steps of the operation, which afterwards turned out very satisfactorily, and completely effected the object I had in view by removing the deformity.

Wry neck may be due to many other causes besides what I have mentioned, such as inflammation of the glands of the neck after scarlatina or measles, or it may be due to contraction of tissues after a large abscess has existed in this situation; a severe burn healing may cause retraction and contraction to either side. It has been found in some very rare cases to be congenital. Large glandular and cystic tumours may so enlarge as to cause the head to turn to either side. An immense goitre may so cause one set of muscles to act more forcibly, owing to paralysis of the muscles on the opposite side, owing to pressure, &c., and in all cases the treatment must vary, according as the causes vary. After division of the muscle it is perhaps better to keep the head for two days or so in the same position, and at the end of that period to bring the head into normal position, which is generally easily effected if it was due to muscular contraction, and thus retained by two light metallic flexible splints, which are nicely padded and bent to any angle or shape required to fit the natural contour of the neck, and extending from the side of the head to the shoulder, and kept applied by a well-fitting bandage. You must be aware that in some cases after division you are very disappointed to find that the case has not been improved in the slightest degree by the opera-

tion; it perhaps has not been fully divided by the operation, or else it is due to constitutional causes, and all the muscles are more or less affected, and mere division of one is worse than useless.

When wry neck is due to rigid atrophy and structural shortening of the muscles of one side, galvanism, blistering, and gentle traction applied by means of an appliance fastened to a band passing round the head, to which an elastic band is attached, and thus connected by its other extremity to a strap or band attached to the shoulder; strychnine internally, or any other strong nervous medicine, if depending on disease of the spinal accessory nerve.

**DISEASE OF THE CERVICAL VERTEBRÆ.**

When considering disease and deformity generally of the vertebral column, the distortion in this region was more or less included. It, as I mentioned before, was liable to become affected by the various deviations that distort the other vertebral regions, and any deformity in this region claims more attention, as greater inconvenience is experienced by impairment of action and other inconvenience owing to the close proximity of the head, and also being endowed with greater flexibility and mobility than other portions of the vertebral column. Caries of the cervical vertebræ occur, as well as posterior, anterior, and lateral curvature, and must be treated on the same principles as curvature in other regions.

Caries of the bodies of the cervical vertebræ may all coalesce, and bony ankylosis and consolidation take place of those bones affected, and permanent stiff neck takes place, which is perhaps the best termination that can be hoped for, or paralysis of the superior extremities sometimes occurs.

**DISTORTIONS THE RESULT OF SEVERE BURNS AND OTHER INJURIES.**

After the receipt of a severe burn by fire, or the application of boiling water or corrosive fluids, if very great care is not taken during the healing and cicatrization of such injuries, a very unsightly contracted cicatrix will be the result, producing at times great deformity; if it has extended very much on the face the eyelids will be drawn down, the lips considerably everted, saliva flowing down the chin, which in turn is bound down by a tough cord-like cicatrix to the sternum. This, with various modifications, is what generally occurs. Some weeks after the receipt of a very severe burn or scald is the time frequently that patients apply for surgical treatment; but it would have been very much better if they had thought of treatment sooner, as very much more might be done by judiciously placing the head in a proper position during the healing process than after the contraction of granulation and cicatrization, &c. Many appliances are made to suit the circumstances of each case, and are frequently of the greatest use. However, if the case is allowed to heal in the usual way, without any regard to the position during healing, more or less deformity is sure to follow, and I am bitterly opposed to those who think that everything is gained when the ulcer heals, and who try and do everything that will favour such a result; and I say most strongly that position is everything, and by proper position much deformity may be spared to the patient.

*Treatment.*

Much can be done by operative means for these cases, and some have to be operated on again and again to remove completely the distressing appearance; a certain amount may be gained by the first operation, the second still more, and so on. Every case, of course, requires certain modifications in operation, the rule being to free all parts that appear to be contracted. Some surgeons divide these puckered bands in the cicatrix *subcutaneously*; others, again, divide them by a *semilunar incision*.

Mr. Skey recommends a number of small *transverse cuts* along the line of cicatrix. The plan I adopt, and one which I think the best, is to transfix the numerous bands connecting the chin to the sternum with a long

straight bistoury ; through the aperture made I pass some silk, or a tightly-rolled piece of lint or gutta percha, and I leave this in such a position inserted in the flesh until I see some pus. I then withdraw the foreign body, and cut the contracted band above or below, just leaving a little islet of sound flesh remaining. This acts by relieving the tension, and tends to rapid cicatrization of what might have taken a very lengthened period to heal. Some transplant pieces of skin after the manner of skin-grafting on the ulcer during the healing process. Figs. 22 and 23 represent a boy before and after operation, which came under the care of my friend and colleague Mr. Smyly, and shows very well the great deformity before operation and the great improvement after.

After operation great attention should be paid so as to place the head in a proper and favourable position, so as counteract deformity, as if this point is neglected the case will retrograde back to the old position, and the operation be rendered of no effect.

FIG. 22.

*Retraction the Result of a Severe Burn before Operation.*

*The same Case Twelve Months after Operation.*

#### DEFORMITIES ARISING FROM GLANDULAR ENLARGEMENT IN THE NECK.

We not unfrequently meet with tumours and chronic enlargement in the neck, which occasionally attain such a size that they are not only most unsightly in appearance, but they are most irksome by their weight and inconvenient position. These swellings vary considerably in size, shape and consistence.

Common enlargement of the lymphatic glands are a very frequent occurrence, terminating in induration, or perhaps in suppuration and abscess ; fibrous, fatty, malignant, and encysted tumours, as well as hydroceles in the neck, may all be met with in this situation ; also

hypertrophy of the thyroid gland, called goitre, or bronchocele, which frequently attains such an immense size, and presents a most distressing and deformed-looking appearance to the person thus affected. As the consideration of diagnosis, prognosis, and treatment is not in the limit of these lectures, I therefore refer you to the various works on surgery, and there you will find the reasons for and against operations fully discussed at great length, according to the importance of the subject.

(To be continued.)

#### REPORT ON SYPHILIS.

By C. R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.,  
Senior Physician to the Metropolitan Free Hospital.

##### TERTIARY LESIONS OF THE HARD PALATE.

THE following translation of another lecture by Dr. Alfred Fournier, delivered at the Lourcine Female Venereal Hospital, will, I think, prove of interest to English readers. It is from a report made by Dr. A. Pichard in *Le Mouvement Médical*, 22nd August.

The tertiary lesions of the mucous membrane which covers the hard palate are exactly like those we have already encountered in other parts of the mouth. They consist simply in this : ulcerated syphilitic affections and gummy tumours.

You have already, gentlemen, understood what is the special interest which is attached to such accidents on this region. The mucous membrane on which they are produced is closely adherent to the bony parts, so closely that it is confounded with the periosteum of the bone, so as to form a *fibro-mucous* membrane. Now, it follows from this that the lesions of this mucous membrane are easily exposed to have an influence on the subjacent osseous tissue, and to attack the bone itself. Moreover, it is useless to mention what are the conditions of the bone itself. Remember that this is the roof of the mouth, a very thin vault, lamellar, formed by the palatine apophysis of the maxillary and the horizontal part of the palatine bone. Hence, however slight may be the injury of this bone, it is exposed by this alone to be destroyed, and, once destroyed, a communication is at once established between the cavity of the mouth and that of the nose. Rationally, this is what is seen by a simple mechanical inspection of the parts ; and, clinically, this is what is produced. Indeed, however little the ulcerations of the hard palate may be grave or hollowed out, they attack the periosteum, and then the bone, and almost necessarily are complicated with the lesion of the skeleton which forms the naso-buccal septum.

If the attack made on the bone be only superficial, its most external portion is alone affected, and becomes exfoliated ; then repair takes place when the little piece has become eliminated, and the palate is not perforated.

But, in other cases, when the bone has been affected more gravely, things do not go on by any means in such a benignant way : the denuded bone becomes inflamed and necrosed over a greater or lesser extent ; a fistulous ulceration persists for some time at its surface, at the base of which a probe can feel portions of necrosed bone ; these portions then become detached ; a perforation takes place which establishes a communication between the mouth and the nasal fossæ.

Such is the origin, or, at least, one of the origins most commonly met with of these perforations of the palatine arch, which constitute a common accident in tertiary syphilis, and one of those which most thoroughly carries with it the stamp of the venereal specificity.

Let us, then, consider those lesions which are of real practical interest.

Their origin is variable.

1. At one time the osseous perforation is established, as we have seen, after a lesion of the mucous membrane

covering the bone, whether this mucous membrane be that of the mouth or the nostrils. In this case it is the tegumentary lesion which is initial, and the bone affection consecutive.

2. Sometimes the opposite takes place: the perforation takes place because the bone was first of all attacked; it became inflamed and necrosed of itself, because of its own lesion; and then the mucous membranes over its two aspects have been injured, as is the case with all teguments covering diseased bone. Theoretically it would seem that it ought to be rather easy to distinguish these two orders of lesions by their progress. Practically, the fact is quite different, and in many cases, even most generally, we cannot say whether the bone has first become diseased or the membrane. This is because the patients do not come to consult us until the lesion has been far advanced, when the mucous membrane and the bones are affected, and it is no longer hardly possible in these conditions to establish a diagnosis of priority between the lesions of the mucous membrane and bones.

A practical fact there is very necessary to establish, and that is the lateral appearance of those lesions which are about to end in perforation of the bony palate.

Whatever be their origin, these lesions arise and become confirmed in a most insidious manner. First of all, they cause no pain. Besides, they have truly no symptom which evinces their importance, even to the most vigilant patient. In what do they consist, not only in origin, but when the mucous membrane is covering a bone profoundly attacked, necrosed, and dead? In little flattened projections on the palate, ulcerated at their summit—projections comparable nearly to what a symptomatic abscess of dental caries is on the gums. The patient considers this a trifle, and frequently he even does not think of consulting any one for so small an affair. Hence, the benignant aspect of the lesion is marvellously constructed to deceive the patient. I would add that it is benignant enough in some cases to deceive the practitioner, who, if he be not forewarned of the special appearance of the lesion, does not always suspect from the story of the patient, or the aspect of the region, the real gravity of the accident which is going on.

Before a lesion of the palate, however innocent it may seem, be then, gentlemen, always mistrustful; even when there is no great local mischief apparent, a bone clearly denuded, do not pronounce about the lesion until complete examination of the condition of the parts. Begin by drawing forth the probe from your dressing-cases, and see what is at the bottom of the wound. This alone will put you out of the power of making a mistake, which is always possible, and will permit you to make a complete diagnosis.

Where do we meet with perforation of the osseous palate most commonly? All points of the bony palatine vault are not equally disposed to become the seat of these perforations by any means. These perforations have favourite spots, which anatomy alone, *a priori*, could make us foresee: 1st, the median central part of the palatine vault; 2nd, the posterior rather than the anterior parts.

The extent of these perforations is very variable. All superable degrees of mutilation of the hard palate are met with in practice—all, from the smallest perforation, hardly admitting a probe, up to the complete and absolute destruction of the palate.

These perforations are pretty frequently rounded, and sometimes very regularly so; frequently they are oval.

The functional disturbances which result from these perforations are exactly those which result from perforation of the velum, *i.e.*, disturbances in phonation and nasal reflux of food and drinks.

And, as in perforation of the velum, these functional disturbances are here remarkable by the instantaneous nature of their appearance. So long as perforation does not exist, and is only being prepared, these disturbances are absent. At the very moment when the perforation takes place these disturbances are manifested. Nothing

need astonish us in this, since they are due to a cause which is quite material and physical.

In the same way as when the velum is perforated, these disturbances are in proportion, as regards intensity and extent, to the perforation of the hard palate.

When once produced, these perforations, of course, remain constant. First of all, they are surrounded by an ulcerating border. This border becomes absorbed under the influence of suitable treatment, the ulcer becomes cicatrised, and the edges of the opening become covered with a fine cicatrix which adheres to the hard parts, that is to say, to the healthy bony parts.

*Treatment.*—To remedy the functional disturbances which result from perforation or destruction of the velum palati, it is necessary and sufficient that the loss of substance should be closed. As soon as the abnormal communication between the mouth and the nostrils has been filled up by any device whatever, the voice is at once regained, and deglutition becomes normal; as soon as the communication is re-established, at once the disturbance is renewed, and so forth.

It is curious in this respect to see sometimes patients who are aware of this phenomenon bestirring themselves to find out of their own accord means more or less strange to fill the perforation and bring back these functions to their physiological condition. Means the most primitive and rudest often suffice for them, at least, temporarily.

For example: A patient I saw some years ago, affected with perforation of the hard palate, through which a pen-holder could easily have been passed, was in the habit of closing the perforation with a pledget of lint rolled up, and could thus speak and swallow as before.

Here is another case, still more singular: some years ago I received the visit of a patient whom I recognised from his first words to be affected with perforation of the palate, because of his confused and nasal voice. Hardly seated, this gentleman commenced by drawing from his pocket a book of cigarette-papers. I looked on with surprise at what he was going to do. He took a leaf of paper, tore off a fragment, moistened it slightly with his lips, then he glued it on the palate where the perforation existed; and all this took place, gentlemen, in the twinkling of an eye, in less time, certainly, than I take in recounting it. At once his voice became clear and quite perfect. After five minutes' conversation his voice suddenly became altered again. "Ah!" he cried, "my paper has fallen off." Again the same manoeuvre followed; a new leaf of cigarette paper was glued over the perforation, and at once his voice was re-established. Any obturator, then, suffices to re-establish the functions. Well, such is the principle on which are based the different methods of treatment applicable to perforations or destructions of the hard palate.

These methods are of two kinds.

The first kind consists in surgical procedures, which aim at uniting the separated flaps of the velum (*staphyloraphy*), or to fill completely by autoplasmic means the loss of substance of the palate (*vanoplasty*). These two methods are applicable, of course, to different cases. It does not enter into my subject to formulate to you either the indications to which these respond, or the operative processes they require. I have only to mention them to you.

But what I ought to tell you is that the use of surgical procedures may in many cases be rendered useless, and that, thanks to the ingenious apparatus which dental art has devised of late years. Dental art, we must recognise, here is of the most signal service to the patients, by delivering them without operation from two equally insupportable infirmities. On the one hand, it does what surgery can do, and it is not without advantage to substitute it for surgical methods, which are not without danger, and do not always result in what was proposed by any means. On the other hand, it is applicable to all cases, even to those before which surgery remains quite powerless.

In what, then, do the remedies it disposes of consist?

In *obturators*, in true artificial palates, or segments of palates, which, when applied on the vault or at the point where the vault existed, and kept motionless by various

means, take its place and fulfil the functions of the palate. These obturators are constructed either of metal (gold and platinum), or, above all, vulcanised india-rubber. They are kept in place either by hooks or by springs, or other artificial procedures, the study of which belongs to dental art, and would be out of place here.

Let us, then, pass over the technical details. The essential for us, and the only fact to register, is the result furnished by these apparatus. Well, when these have been well constructed, adapted to the regions, and well tolerated by the patients, they almost always furnish satisfactory results, even marvellous in certain cases. With such apparatus the patients can masticate, swallow, and speak almost as well as normally. Sometimes even, and when they have exercised with the apparatus, the functions are absolutely and perfectly re-established. The illusion is then complete, and these artificial palates are substituted almost without disadvantage for normal palates. I have already seen many patients who, affected with perforation or destruction of the palatine arch, and being able neither to speak intelligibly, nor to swallow without reflux, have regained the integrity of those functions, thanks to artificial apparatus cleverly constructed.

To give you a striking example : One of the most celebrated dramatic artists of our time (I regret not to be able to name him) wears one of these artificial palates, which fills up an enormous loss of substance on the hard palate. Without the assistance of this apparatus he cannot speak—his voice becomes at once nasal and trembling and confused. With it he eats and drinks like anyone else, and he speaks especially not like anyone else, but better than anyone, the proof of which is the applause which you and I have often bestowed on him,

## INDIAN MEDICAL NOTES.—No. XXVII.

(FROM OUR SPECIAL CORRESPONDENT.)

MEERUT, September, 1874.

### "THE UNCERTAINTY OF LIFE."

ENCLOSED is a Register of Observations recently supplied. Tables will be sedulously avoided in the medico-serial notes concerning this great country, wherein and whereof it is my pleasure to write ; but so little is really known about Simla, the summer residence of the rulers of this land, that the kind indulgence of the reader interested in India need scarcely be solicited. Who has not some acquaintance here? Though we correspond, still many thousand miles separate husband and wife, children and parents, lovers, relations, friends, not a few of whom have shaken hands, and said, for the last time, that sad and cruel word "farewell!"

With a plethora of matter, I can think of nothing to-day excepting the universal fever prevalent at Meerut. Those affected last year are stricken again ; those who escaped then are down now ; out of a small body of men only three remain well—all total abstainers ; other total abstainers occupy sick-beds adjoining the topers—the fever is no respecter of persons, sometimes simple ague, sometimes typho-malarial striking down the steadiest, the finest, and the best of men. Nor is the disease trifling, for night and day are cases in extreme peril anxiously watched. It may happen that the recreation of scribbling thus may indefinitely be postponed. It may not be out of place to mention some of the names of those at Simla this year, for the information of their friends : Lord Napier and staff, Sir Douglas Forsyth, Generals Johnson, Gaze, Rothney, Colonels Arbutnot, R.A., Bleuitt, 65th, Dillon, Cox, Thuillier, Roberts, Cordner, Maisey, McKay, Madden, 51st, Massy, Rattray, Brooke, Russell, R.E., Hutchinson, and majors and captains innumerable, a few civilians, a few clergymen, Drs. Currie, C.B., Ogilvy, Alexander

Smith, Bryden, Inglia, Morice Sutherland, Tressider, Kidd, Kellett, Hogg, Garden, Calthorpe, Temple Wright, Bradshaw, Warren, and others. Some of these were patients, some were friends whose kindness and hospitality will ever be most gratefully remembered. At Simla the medical officer may, if desirous, go in for practice ; I had the chance of receiving several very handsome liberal fees, ranging from £5 to £20, but for reasons and circumstances too long to be detailed now, only accepted £30 for consultations from civilians.

Concerning Kussuvlee, Dugshaie, Subathor, Sanawar, perhaps a few words may be said another time, when the sickness at Meerut will afford leisure. This is the first of September : a full hospital, the whole station prostrated by fever, perhaps to be followed by cholera. The place is very green, the Mall deserted, only three or four ladies here, mostly sick ; any amount of birds, flies, frogs, creating discordant sound. "Did you do it?—did you do it?" shrieks one dismal bird with irritating monotony, by no means conducive to composition. A certain amount of ophthalmia, cases of aneurism, hepatic abscess, besides fever, occupy attention. One woman has three children : the eldest, a girl of ten, is always well, the others always sick. Another woman, born in the country, she and children are fairly well. The rest suffer from malarial cachexia, enlarged spleens, fever, ague. Hypodermic injections into the trunk of the body of the neutral sulphate of quinine are being used right and left, also recorded for future notes. The cold baths for enteric fever are greatly enjoyed by the sick, but the temperature is only reduced for the time—105° to 106° we think nothing of ; so far, in my opinion, cold baths at certain stages, strychnine at others, are invaluable remedies. The other day, when a catheter could not be passed, the aspirator at once relieved the distended bladder ; but until india-rubber tubing is dispensed with, this priceless instrument will never keep in good repair in Bengal.

Cursed be the clerk and parson ; cursed be the whole concern ; or rather, after the fashion of the Jackdaw of Rheims, accused be the bird. "Did you do it?—did you do it?" still he shrieks, so, enclosing the meteorological table in despair, and with gloomy forebodings, I lay down the pen to-day with just a word of apology for the style, bad grammar, jerking, irrelevant incoherence characteristic of these "Notes." Should the fever abate, and cholera be staved off, there are interesting cases innumerable to relate.

REGISTER OF OBSERVATIONS for Rainfall during 1870, '71, '72, '73, and of Maximum and Minimum Thermometers during 1871, '72, '73, taken at the Quarter-Master General's Office, Simla. Rain gauge observed daily 3.30 p.m. Thermometers at 10.30 a.m. Thermometers in shade with north aspect.

## BLOODLESS SURGERY.

THIS subject, which has for some time engaged much of  
 the attention of hospital surgeons, received a new impetus at  
 the first meeting of the Clinical Society this year, in con-

sequence of the presence of Professor Esmarch, who delivered, in excellent English, an address on his method of attaining the desired end. He employs, as our readers are aware, elastic webbing and bands, and although not the first to entertain the idea of operating in this manner, he has carried the plan so far, and had so large a share in perfecting it, that he is regarded by many as the inventor of it.

It is unnecessary here to enter into the vexed question of priority. Our intention to-day is to give an account of Professor Esmarch's method as expounded by him at his late visit to London, and of the remarks called forth on that occasion. He prefaced his address by observing that many surgeons with whom during his visit he had conversed were imperfectly acquainted with his method—a reproach which will not, we should hope, henceforth be applicable. He then said that others used it, but not rightly; whilst others did not consider the prevention of loss of blood of any importance. Although the object of the method was to get good results in surgery, the only mode of proof of its value was its influence on the mortality after operation, especially after the amputation of limbs. A comparison of his results with those obtained by the anti-septic method was favourable, but he admitted that this is obviously inconclusive, from the difference in the hospitals in which they were treated, and the necessity of detailed accounts of individual cases. He therefore compared the statistics of cases in his own practice prior to and after the introduction of his method, and obtained striking results. Out of 88 cases of amputation of the thigh before its introduction, 37 cases, or 42 per cent., died; whilst of 67 of amputation of the leg, 19 died, or 28 per cent. Since its employment, out of 13 cases of thigh amputations, only 1 had died, and only 1 of 12 leg amputations, reducing the mortality from 36 per cent. to 8 per cent. for amputation of the lower limb. Even making allowance for the difference in numbers, these results tell strongly in favour of the bloodless method. Its employment, however, was by no means limited to operations on the limbs, but may easily be applied to other parts. For example, in cases of excision of the shoulder-joint, a piece of elastic tubing may be passed under the armpit, and held over the shoulder by an assistant, or, if the operation is prolonged, it may be fixed by means of an ovariotomy clamp. If this prove insufficient, other means can be used. Professor Esmarch illustrated this by a case that he had under his care last summer. It was that of a man between fifty and sixty years of age, suffering from a tumour the size of an ostrich egg in the axilla, which had been growing two years. Its removal was absolutely necessary, on account of the intense pain which he suffered. The tumour was wedged in between the scapula and the chest wall, firmly adherent to and moving with the scapula, but not with the humerus. Microscopic examination of a small portion showed its structure to be myxo-sarcomatous. As these growths often arise in the sheaths of nerves, it was thought to originate from the sheath of one of the cords of the brachial plexus, and on account of the probability of recurrence, removal of the whole arm with the scapula was decided on. The arm was bandaged with elastic webbing as far as the shoulder, and the outer two-thirds of the clavicle then removed in

order to ligature the subclavian, the pulsation of which could not be felt from the surface. Both artery and vein were ligatured, and the cords of the brachial plexus cut across, and the arm was then removed with the scapula by anterior and posterior skin flaps. The edges of the flaps were united by sutures, and under carbolic oil dressing they united speedily. Professor Esmarch went on to show that superficial tumours—*e. g.*, erectile tumours of the scalp in children—may be readily removed, without hæmorrhage, by introducing needles and applying around the tumour elastic tubing. Operations on the male genitals may similarly be performed, after passing a piece of tubing tightly round the root of the penis and scrotum. As an illustration of a still more advanced use, Prof. Esmarch related the following case: An old man came under his care last winter with extensive epithelioma of the penis, which involved the under-surface of the penis and the scrotum, forming a cauliflower mass the size of the palm of the hand, which bled freely and discharged an ichorous fluid. The urine escaped from a fissure in the centre of the growth. The inguinal glands were much enlarged, and there was great emaciation. For the operation, an elastic tube was passed round the root of the penis, over the front of the thigh on each side, and crossed over the sacrum. The penis and anterior wall of the scrotum were now removed, and then the enlarged glands in the groin with the integuments covering them; the crura penis were afterwards carefully dissected away from the corpora cavernosa and removed; and, an incision in the median line having been made, the scrotal flaps were made to cover the exposed surface in the inguinal regions, and the urethra attached to the edges of the wound. Shortly after the operation, symptoms of pleurisy supervened, and death occurred from extensive cancerous deposit in the lungs. With regard to the results of the method, of three hundred cases in which the bloodless method has been used, no evil has followed in any one. Even in the longest operation—which lasted two hours and a quarter, and which was in a case of necrosis of both tibiae, with resection of one knee in addition—no harm was done by the prolonged absence of the blood. This objection was not therefore valid.

In the discussion which followed this address Mr. MacCormac said that, although no London surgeon had seen so many as 300 cases, he had found no bad results in any case from the employment of the method. In the only case in which marginal gangrene of flaps had been said to have occurred he believed other causes had been found to exist. The only operation in which a question might arise as to its applicability was excision of the knee-joint, when the oozing due to the sudden return of the blood to the weakened capillaries might be inconvenient by spoiling the splint and necessitating movement. The method has great advantages in the examination of injured parts and the search for necrosed bone.

Mr. Henry Lee regretted that Professor Esmarch had not distinguished between two classes of cases—*viz.*, those in which the blood was left in the part removed, and those in which it was previously driven out by compression. In the former class he did not see any advantage in the use of the elastic bandage over the clamp. Of the other class, he mentioned a case of tumour in the

palm of the hand, the removal of which would have been impossible without Esmarch's method.

Mr. Clover ascribed the superficial sloughing of the flaps in the case mentioned by Mr. MacCormac to caustic action of the carbolic acid spray on the surface when not neutralised by the alkaline blood. He considers the ordinary tourniquet with a narrow bandage better for encircling the limb, as it is not liable to snap like the elastic tubing when brittle from keeping.

Mr. Prescott Hewett said that, having assisted at the operation, he considered Mr. H. Lee's case alone a sufficient proof of the value of the method. He believed it would have been impossible otherwise, the tumour being attached to one of the metacarpal bones, and closely surrounded by the vessels; as it was, the operation was only a dissection, the parts looking like a wax model.

Professor Esmarch, in reply, said that he did not see how the clamp could be applied in such cases as for the scrotum, &c.; while, if it could, it would only be another application of the bloodless method, and the india-rubber tubing was simplest. He had never seen it break, and did not see how it could if well applied and of good material. He pointed out that a common tourniquet is passive, while the elastic rope is active in its pressure; and certainly the distinction is worth remembering.

Altogether, the Clinical Society may be congratulated on Professor Esmarch's visit.

#### ADULTERATION PROSECUTIONS.

SEVERAL prosecutions have taken place within the last week which are fraught with much interest to those who are anxious for the successful working of the Adulteration Act, as well as to the public who are being cheated and the traders who are cheating them. They are cogently illustrative of the utter roguery of a certain class of unscrupulous dealers and of the wriggling of manufacturers in the endeavour to escape the necessity of honestly stating the constituents of what they sell.

At Bradford a man named Knight was prosecuted for selling "Liebig's Liquid Extract of Beef," which was stated to be "the only beef extract that does not require cooking or warming, it being in the form of a liquor. It is composed chiefly of pure extract of beef, obtained from the best parts of the animal, wine, a small quantity of fine old brandy, and quinine." The town clerk stated that the so-called "Liquid Extract of Beef" contained a very minute portion of beef, no quinine, no Madeira wine, and no brandy, but something else to make it palatable. Directions were given on each bottle to the effect that "invalids may take a wineglassful three times a day. This quantity has been found to sustain life for months when the patient could not retain any other kind of food on the stomach." The borough analyst, however, swore that the article contained hardly any beef, and was mainly composed of Tarragona wine, sweetened with sugar and flavoured with allspice, containing 15 per cent. of pure alcohol. "There was," he said, "no quinine, no brandy, no Madeira, and it appeared to him to be merely a sly method of drinking." The defence was that the prisoner obtained the preparation from the "highly respectable" firm of Digby, Gandy, and Co., of Liverpool; but the

magistrates properly refused to accept such plea, and fined him £2 and £2 10s. costs. If they could have sent the members of the "highly respectable" firm or the equally respectable makers of the compound for three months to the treadmill the judgment would have been nearer to the level of justice.

In three other cases the defendants were charged with selling adulterated mustard without plainly declaring the admixture. In one case the addition to the mustard-flour was described on the label as "choice condiments," but was in reality turmeric *pur et simple*; in another the adulteration was 30 per cent. of starch; and in a third the sophistication was 20 per cent. of flour and turmeric, and on the label were the words, "This is an admixture in which no injurious ingredient has been used." The question arose as to whether this announcement was sufficient notice to the purchaser, and the magistrates ultimately dismissed the summons, under guidance of a judgment given in a previous case by Lord Chief Justice Coleridge and Justices Brett and Grove. The judgment quoted was that in the appeal of *Pope v. Tearle*. We reproduce it here:—

"Lord Coleridge: I think the respondent is here entitled to our judgment. There are two sections of the Act (35 and 36 Vict., cap. 74) which bear upon this case, and it appears to me that the facts bring him within neither of them. It appears to me that the true and reasonable construction of the Act interprets it thus: Whereas the phrase in the former section contemplated the case of the adulteration being by means of some noxious ingredient, the 3rd section went on to say, if an article of food or drink be mixed with a substance not noxious, but fraudulently added for the purpose of increasing the weight or bulk, and it be sold by a person knowing this who does not declare it, then such person shall be guilty under section 2. The respondent here is not within it; for though he sold an article so mixed, yet, by language and by label, he affected the purchaser with knowledge, and so did declare the admixture. He is not therefore within section 3. But supposing that he had not declared the admixture, and had sold, then he would have been brought within section 2. As it is, however, he is not within the latter section, for the simple reason that he has not here sold as unadulterated any article of food which was adulterated.

"Justice Brett: I am of the same opinion.

"Justice Grove: I read the Act in this way: Sections 1 and 2 contemplate the mixing of noxious ingredients in articles of food and drink. The 3rd section, in order to avoid any doubt as to what adulteration is, says that the admixture of foreign substances, whether noxious or innocuous, is all the same adulteration. Is there anything in the section to make it necessary for the seller to declare what is the substance and quantity of the materials mixed? I think not. The words '*and no other*' in the 3rd section may well mean no noxious substance—nothing, that is to say, except for the purpose of increasing the weight. Judgment must, therefore, be given for the respondent (the grocer)."

#### SOCIETY OF MEDICAL OFFICERS OF HEALTH.

At the meeting of the Society on Saturday evening last, Dr. Letheby, the President, delivered an address on "The Estimation of the Sanitary Condition of Communities, and the Comparative Salubrity of Towns." He said that this important problem is not nearly so simple, or so easy of solution as is generally supposed, and that the common and vulgar method of estimating it by the death-rate, as usually calculated, is entirely fallacious. In proof of this he alluded to the disturbing effects of migration,

the birth-rate, the proportion of the two sexes, and other circumstances in vitiating the results, and he quoted a number of authorities in proof of it. As regards migration, he said that when there is a notable migration of young adult lives from country to town, as is generally the case, the death-rate of the rural district in which the young lives have been produced is unduly augmented, while that of the town, which acquires such lives without the vital cost of rearing them, is proportionately reduced. This is the condition of things in every large town in the kingdom, and he took London as an example. Seven-and-twenty years ago the population of London, as determined by the census of 1851, was 2,362,236. In 1861 it amounted to 2,803,989 persons; and at the last census, in 1871, it was 3,254,260, so that in twenty years the total increase was 892,024 persons, or nearly 38 per cent. The natural increase in that time, as estimated by the excess of births over deaths, was only 595,111, or only about 25 per cent., the difference, therefore, namely, 296,923, or nearly 13 per cent., is referable to the additions made to the population by the entrance into it of fresh lives, and this is altogether independent of the large number of such lives which took the place of those who, from sickness or other cause, left the metropolis to live and die elsewhere. All these were young healthy lives, at perhaps an average age of 20, and the cost of producing them must have been considerable. In London the death-rate of infants is so large that not more, and probably much less than 60 out of every 100 born, live to be 20 years old. At this rate the 296,923 young adults who were added to the population of London during the last twenty years, would, if they had been produced here, have cost 494,872 births, and 197,949 deaths, not one of which has appeared upon the registers of the metropolis. It is hardly possible to compute the exact number of young persons who, in addition to the preceding, have come to London and taken the place of the sick and infirm who have left it; but an examination of the census will show that nearly half the population of London are aliens, and have migrated to it from the provinces. Probably the net immigration during the ten years from 1851 to 1861 amounted to 31,820 persons per annum, or rather more than double the annual number of young recruits (13,356), which, as before said, went to the increase of the population. Assuming that they were at an average age of 20, they would, if they had been produced in London, have cost annually 53,030 births, and 21,213 deaths. Some of these or their equivalents may have appeared upon the registers; but it is easy to perceive how the vigour as well as the numerical strength of London is maintained without the cost of infant life, and that which is a gain to London is necessarily a loss to other places. How much the statistics of mortality have been disturbed by such migrations cannot be precisely estimated; but no doubt they have been vitiated to such an extent as to render them useless as exponents of facts. Dr. Letheby showed from another set of facts, namely, the proportions of males and females at different ages in the population of London, that there was a large influx of young adult lives; for although the proportion of children in the population of London is relatively small, especially in the heart of the city, where it amounts to only 263 per 1000 of the population, as against 356 for all England, yet the number of young persons, at from 15 to 35 years of age, is strikingly large. In the City proper it amounts to 415 per 1000 of the inhabitants, and in the whole metropolis it is 360 per 1000; whereas in England and Wales it is but 335 per 1000. At 55 and upwards the number for the metropolis is only 89 per 1000, as against 105 for all England. The proportion of females also in the population of London is very large. In the heart of the city the number of women at from 15 to 55 years of age amounts to 337 per 1000 of the inhabitants, and in the rest of the metropolis it is 315 per 1000, although for England and Wales it is only 280 per 1000. All this is attributable to the migratory character of the population of London, for at

the census of 1861 there were more than half a million persons who could hardly be said to have a fixed home in London. There were, for example, 153,104 female domestics, besides about 96,400 milliners, dressmakers, shirt-makers, sempstresses, &c., of less than 35 years of age; and these, with rather more than 257,000 shopmen, porters, messengers, clerks, servants, labourers, mechanics, &c., make up a total of 506,676 persons under 35 years of age, who would doubtless leave London when from sickness or other cause their labour became unremunerative. This is clearly shown in the tables of mortality at different ages. Up to the age of 10, and after the age of 25, in the case of males, and 35 in that of females, of death-rate in London is much greater than it is in all England; but at the intervening ages, from 10 to 25, and 10 to 35 respectively, the death-rate in London is much below the average, showing that persons at those ages go away from London when sickness oppresses them; and this is further proved by the fact that, as the mortality falls in London, it rises in the neighbouring counties where the sick and infirm resort. The disease which most strikingly exemplifies this is phthisis, a disease which not only attacks persons in the prime of life, but also gives them ample opportunity for removal to the country. Dr. Letheby therefore concludes that the gain to London by such migrations is three-fold—in the first place, the population is constantly receiving a large number of young adult lives without the vital cost of producing them; in the second place, it gains by the substitution of such lives for the weak and ailing; and in the third place, it gains by the fusion of such lives of high value with the general mass of the population of comparatively low value: for at the age of 20 the death-rate is only about 7 per 1000, whereas that of the general population is more than 24 per 1000. A like condition of things prevails in all the cities and large towns of the kingdom, and it so seriously disturbs the death-rate, as usually calculated, as to make it no longer expressive of facts. In those cases where sick persons resort to public hospitals or to the favourite sea-side places of England, the disturbance is still greater. There is a good example of this in the western division of the city of London, where St. Bartholemew's Hospital is situated, for, according to the returns of the registrar-general, the average death-rate of that district is from 45 to 50 per 1000, whereas the true death-rate is from 27 to 29 per 1000. In like manner the death-rates of Whitechapel, of Islington, and of other districts of London are disturbed by the presence of large hospitals. Another circumstance which destroys the sanitary value of a death-rate is the birth-rate: this is illustrated by the fact that wherever the birth-rate is high, the death-rate is high also, and this is observed not only among the nations of Europe, but also among the registration counties and districts of England. France, with a birth-rate of only 26·26 per 1000 of the population, has a death-rate of only 23·63 per 1000; but Austria, with a birth-rate of 39·86 per 1000, has a death-rate of 30·34. Spain, Italy, and Prussia, exhibit the same general relation; and in England the registration divisions, the counties and the towns show a similar condition of things. Taking, for example, the ten registration divisions of England and Wales, it will be noticed that the birth-rates and the death-rates are closely comparable. Beginning with the south-western counties, where the birth-rate is only 32 per 1000 of the population, and the death-rate less than 20 per 1000, it will be noticed that, as we pass on in the order of increase, the birth-rates and death-rates advance together, so that when we come to the last of the series—the north-western counties, where the birth-rate is 39 per 1000, the death-rate is 26·3. The same thing is observable in the individual counties of England. Twenty of them have an average birth-rate of from 30 to 33 per 1000, and a death-rate from 18 to 21 per 1000, while the rest of them (21 in number) have a birth-rate which ranges from 33 to 42 per 1000, and a death-rate from 19 to 27. In the former group the mean birth-rate is 31·8

per 1000, and the death-rate 19·6; and in the latter they are 35·7 and 22 respectively. As a general fact, it may be said that, where the birth-rate is from 30 to 31 per 1000, the death-rate is about 19; where it is from 31 to 33, the death-rate is nearly 20; where it is from 33 to 35, the death-rate is nearly 21; where it is from 35 to 37, the death-rate is nearly 22; and where the birth-rate exceeds 37 per 1000, the death-rate averages 24·4. As individual examples, the Ridings of Yorkshire may be taken as good illustrations. In the North Riding the birth-rate is 33·9 per 1000, and the death-rate 20·5; in the East Riding the numbers are 34·5 and 22·7; and in the West Riding they are 33·1 and 21·9. It is not possible, without considerable labour, to compare the birth-rates and death-rates of the town and rural districts of England; but Dr. Stark has done this for Scotland, and the results are remarkably instructive, for in the principal towns of Scotland, where the population exceeds 25,000, the average birth-rate is 38·73 per 1000, and the death-rate 28·25. In the large towns, with a population of from 10,000 to 20,000 persons, the birth-rate is 38·07, and the death-rate 24·57; in the smaller towns the numbers are 36·44 and 21·24; and in the rural districts they are 31·49 and 16·93. So also if we take the large towns of England and Scotland and group them according as the birth-rate is over 38 per 1000 or below it, it will be found that in the former case the average birth-rate is 39·6 per 1000, and the death-rate 29·5; whereas, in the latter the numbers are only 34·4 and 25·7. These facts are indisputable, and, according to Dr. Letheby, they afford conclusive evidence of the reciprocity of these numbers. They show, indeed, that they are in some way mutually dependent, or perhaps related as cause and effect. Dr. Stark believes that a high birth-rate is an effort of nature to compensate for the excessive waste of life in large towns; and the registrar-general appears to hold to a like opinion, for he says that, "wherever from the combined effects of intemperance, dirt, bad ventilation, and drainage, the mortality is greatest, there also the ratio of births to the population is highest." But Dr. Letheby reverses the argument, and says, with Mr. Andrew Watt, of Montreal, that "whosoever the ratio of births to the population is highest, there also the mortality is greatest, and the conditions being equal, will be in proportion to the birth-rate." Dr. Letheby has already expressed this opinion in one of his annual reports of the sanitary condition of the City of London, and the registrar-general has replied to it in a memorandum of the "Significance of Rates of Mortality." But Dr. Letheby complains that the document is obscure, and does not touch the question at issue, but raises a new question as to the effect of an excess of births over deaths, saying that "the mortality of a population with an excess of births over deaths is lower than the mortality of a stationary population where the births and deaths are equal." Although this is no part of Dr. Letheby's proposition, yet he accepts it as proof of the relationship of births and deaths. It is curious, however, says Dr. Letheby, to note that the registration facts of the country do not support the registrar-general's proposition, but show that as the excess of births over deaths becomes larger and larger, so also does the mortality of the population. If the registration counties of England be arranged in the order of birth-rates it will be found not only that the death-rates advance with the birth-rates, but also that the excess of births over deaths becomes larger. Where, for example, the birth-rate ranges from 30 to 32 per 1000 of the population, and the death-rate averages 19·2, the excess of births is only 11·9; where the range is from 32 to 34 per 1000, and the average death-rate is 20·1, the excess is 12·8; and so on step by step until we reach an average birth-rate of 39·8 per 1000, with a death-rate of 24·7, when the excess is 15·1. The explanation of all this is to be found in the fact that the mortality of infants is excessively high (46·5 per 1000 in the first month of their existence, and 150 per 1000 in the first year), and that it contributes very largely to the total mortality. In all England and Wales, where

the average birth-rate is 35·2 per 1000 of the population, the deaths of children under 5 years of age amount to 40 per cent. of the total mortality. If this were not so, the natural rate of increase of the population would be prodigious. At present the annual excess of births over deaths in England and Wales is 12·8 per 1000 of the population; but suppose that it was 18 per 1000, as it is in two of the registration counties of England, the population would be doubled about every 40 years; so that the 22,712,266 of the census of 1871, would become rather more than 45 millions in 40 years, and nearly 91 millions in 80 years, which in a long time, in 120 years, or about two generations, would be nearly 182 millions, which is the estimated population of India. But this sort of thing could never last, for in about 240 years the population of England and Wales, unless it was exported year by year in enormous masses, would reach to rather more than 1,550 millions of persons, who would be as thickly placed over the whole country as the inhabitants of London are at the present moment. Happily this cannot happen, for, despite the views of the registrar-general, the birth-rate is the controlling element of the death-rate, and before the relative health of different communities can be compared the apparent rate of mortality must be corrected for the rate of increase by births as well as immigration.

Another circumstance which seriously interferes with the value of the death-rates as estimated in the usual way, is the relative proportion of males and females in the population, for as their death-rates are different (23·3 and 21·5 per 1000 respectively), the common death-rate must necessarily be influenced by it. In infancy and childhood the death-rate of males is nearly 10 per 1000 above that of females, so that in large cities where women and children abound, the death-rate must be under the normal proportion.

Other circumstances were referred to by Dr. Letheby, and illustrated by examples, as affecting the death-rates of the country. He showed that the practice of grouping places together under the name of some one town or place within the district was a source of error, and he referred to the fact that the census numbers of the population, taken in haste and at long intervals, were too uncertain for statistical purposes, and he quoted Mr. Sargant to show that the population of England and Wales was underrated by more than half a million—2·3 per cent.; that with respect to persons under twenty years of age, it was underrated by 5·5 per cent.; and that in the case of infants of less than a year old, the numbers were deficient to the extent of 12 per cent. with males, and 10·5 per cent. with females. In the second year of life the deficiencies were 11·5 and 11 per cent. respectively; and in the third year they were 2 and 1, making an aggregate deficiency of from 6 to 7 per cent. in the return of children under five years of age; and this deficiency was most irregular, being greater in some places than in others, and therefore irregularly affecting the death-rate. In addition to this, the common method of computing the population of a place from year to year between the census periods was eminently faulty, as the rate of increase was uncertain, there being no accurate registration of births, a faulty registration of deaths, and a total ignorance of the migratory movements of the population. Any attempt, therefore, to deduce laws from such imperfect dates must necessarily result in failure, and it is absurd to suppose that the mere proportion of deaths to an uncertain population is any proof or evidence of the favourable or unfavourable condition of the health of the people. In determining so important a question, reference must be made to the ages, habits, and employments of the inhabitants, casual immigrants must be distinguished from permanent residents, and the loss by emigration, especially of sick persons, must be inquired into, the proportion of the sexes, the number of births, the vicissitudes of climate and seasons, calamitous events, and other modifying circumstances must be carefully examined. Until this is done the death-rate, as usually

calculated, and ostentatiously paraded as an indication of salubrity, is not merely ridiculous, but threatens, as Mr. Rumsey says, to become a public nuisance. What more striking proof, indeed, can we have of the untrustworthiness of these so-called "death-rates" as evidences of sanitary progress than the remarkable fact that they remain unaltered, and, as it would seem, unaffected by such progress. Look at the enormously large amount of sanitary work which have been accomplished in London and in the large towns of England during the last twenty years; yet the death-rate, as calculated in the usual way, remains the same. In the City of London during the last three decades the death-rates were 25·20, 24·94, and 25·11 per 1000 of the population. In the whole metropolis they were 24·48, 23·86, and 24·14 per 1000. In the large towns and town districts of England they were 24·45, 23·52, and 25 per 1000, and in the whole of England they were 22·64, 22·11, and 22·69, differences which are insignificant when we consider how much has been done to improve the sanitary condition of the country.

Dr. Letheby then examines the method of determining the sanitary condition of a place by the death-rates at different ages, and he shows that, although this is a better method than the last, yet it is not sufficiently accurate for sanitary purposes, inasmuch as the errors of the census, the migrations of the people, and other circumstances invalidate the results. Taking the death-rate of children under a year old as an example of the difficulties of the case, he shows that the census number of such infants gives most inaccurate results; the census number, in fact, is the number of such infants living on a particular day, and born within twelve months of that day; whereas the deaths which have occurred in the year embrace not only the deaths of those born in the census year, but also of those born in the preceding year, and not a year old at the time of death. Suppose, therefore, that the real death-rate of male infants was 160 per 1000: of this number 50, or nearly one-third of the whole number, will have occurred in the first month of existence, 18 in the second, 13 in the third, and so on in a gradually decreasing ratio to the end of the year, when the number will be less than 7. It follows from this that every 1000 infants born at regular intervals during the year will lose by death 105 during the census, or calendar year, leaving 895 to be registered or enumerated at the time of the census; but the real number of deaths of infants under a year old has been 160—viz., 105 of those born in the census year, and 55 of those remaining over from the preceding year. The death-rate, according to this method of computation, will be 160 per 895, or nearly 179 per 1000; whereas the true death-rate is only 160 per 1000. A like error, though not of such magnitude, pervades the whole of the death-rates, and even the aggregate death-rate of the country. It is manifest, therefore, that the death-rates, as usually calculated, are not expressive of facts, and cannot be accepted as reliable exponents of the sanitary condition of a place.

Dr. Letheby concluded his address by referring to the circumstances which must be considered in estimating the salubrity of a place, saying that the sickness and mortality of young children, when properly estimated, are the signs of home influences; the like phenomena of adults are the indications of wholesome or unwholesome habits, occupations, &c.; and that the sanitary condition of a population can only be properly determined by reference to the statistics of disease as well as of mortality, and that all the modifying circumstances of age, sex, migration, climate, season, &c., must be carefully considered. He promised to pursue the subject in this direction.

---

PROFESSOR WILLIAM TURNER. M.B., F.R.S., of the University of Edinburgh, has been appointed Lecturer on Anatomy and Physiology on the Aris and Gale foundation of the Royal College of Surgeons of England.

## Notes on Current Topics.

### A New Tonic—"Boldo."

RESEARCHES have been made by Messrs. Dujardin, Baumetz, and C. L. Verne on this proposed addition to our list of medicines.

Boldo is a tree found in Chili, of a height of five or six feet, isolated on mountainous regions, with yellow blossom and a verdant foliage. Its bark, leaves, and blossom possess marked aromatic odour, resembling a mixture of turpentine and camphor. The leaves contain largely an essential oil. It contains an alkaloid which is already called "holdine." Its properties are chiefly as a stimulant to digestion and having a marked action on the liver. Its action was discovered rather accidentally—thus: Some sheep which were liver-diseased were confined in an enclosure which happened to have been recently repaired with boldo twigs. The animals eat the leaves and shoots, and were observed to recover speedily. Direct observations prove its action—thus, one gramm of the tincture excites appetite, increases the circulation, and produces symptoms of circulatory excitement, and acts on the urine, which gives out the peculiar odour of boldo.

### Health of Kensington.

FROM the report of Dr. Dudfield, medical officer of health, it appears that the mortality during the year 1873 was the lowest on record. In his report he gives the following figures, which show the death-rate in Kensington, the metropolis generally, and the great divisions into which it is mapped by the Registrar-General.

The death-rate in 1873 was: In Kensington, 18·3 per 1,000; London, 22·5; West Districts, 20·5; North, 21·2; Central, 25·0; East, 25·0; South, 22·0.

The deaths from the seven principal diseases of the zymotic class were 290, equal to 119 per 1,000—viz.: Small-pox, 0·4 per 1,000 deaths; measles, 15·6; scarlet fever, 4·1; diphtheria, 4·5; whooping-cough, 18·0; fever, 16·8; diarrhoea, 59·6. It appears that Kensington is about the healthiest suburb.

### Scarlatina in Ireland.

THE latest report of the Registrar-General is not more assuring than that to which we referred last week. The weekly return states that the deaths in the Dublin district were 27, and those in Belfast 28. The return for the quarter ending October 3rd is still more unsatisfactory. The Registrar-General reports that in Dublin scarlet fever proved fatal in 250 instances, in other words, 1 in every 7·6 of the total deaths resulted from this disease. For the last twelve months scarlet fever has been epidemic in Dublin, and during that period 747 deaths have been caused by it, i.e., 9·2 per cent. of the total deaths registered, and 24 in every 10,000 of the population. The deaths from this plague were distributed during the four quarters as follows: In the last quarter of 1873, 151; first quarter of the present year 170; second quarter 176; and third quarter 250; showing that the epidemic has been steadily increasing instead of diminishing.

### Poisoning from Eating Tunny.

THIS fish, which is eaten much in France and southern Europe, has not been accredited usually with any bad qualities. In the Parisian markets it is rather prized. It tastes something like veal, and is firm and white. The *Semaphore Journal* records a case of four people who, having eaten a *friture* of tunny, were seized with urgent symptoms of poisoning—vomiting, headache, purging, and febrile symptoms. Such accidents were attributed rather to something on which the tunny had fed than to any degeneration in the fish itself.

The sufferers all recovered, though they had been severely affected.

### Scarlet Fever in London.

SCARLET fever is now so prevalent in London that most of the vestries are issuing printed directions for preventing the spread of the disease. The Local Government Board has prepared the Homerton Small-pox Asylum for the reception of patients suffering from scarlet fever. The building has been disinfected, and is now ready for use.

### New Medical Students.

THE following return of students entered at the metropolitan medical schools since October, 1873, includes, as will be seen, last summer's entries, and the register is not yet complete, so that a few more will doubtless be added to the roll: St. Bartholomew's 109, Guy's 86, University College 81, St. Thomas's 79, St. George's 44, Middlesex 44, London 36, St. Mary's 33, King's College 26, Westminster 23, Charing Cross 22. Returns are not yet made for the provincial schools, but we hear that they are about the average. At Birmingham 26 new students have already entered.

### Patrick M. Mackenzie, M.D.

ON the 19th inst. died, in London, Dr. Patrick M. Mackenzie, youngest son of the late Kincaid Mackenzie, Esq., Lord Provost of Edinburgh in 1817-19. Dr. Mackenzie was born in 1821, and educated at the academy and university of his native city. He graduated as M.D. in 1844, and went to Tobago in 1847, and has since practised there.

### Scarlet Fever in Liverpool.

SCARLET fever has broken out at Liverpool. On the 14th two men were fined for having let houses which had contained fever patients without having had them disinfected. A good example this.

### Soorjocoomar Goodeve Chuckerbutty, M.D.

ON Sept. 29 died Dr. Soorjocoomar Goodeve Chuckerbutty, Physician to the Calcutta Hospital, Professor of Materia Medica and Clinical Medicine in the Calcutta Medical College, and Surgeon-Major in the Bengal Army. Dr. Chuckerbutty obtained two years' leave of absence from India, and soon afterwards came to London. While there his health apparently improved, and he was present at the meeting of the Association in Norwich. He was only forty-eight years old. Dr. Chuckerbutty was the youngest of four natives of India who came to study me-

dicine at University College in 1845. He took the degree of Doctor of Medicine at the University of London in 1849, and became a member of the Royal College of Surgeons of England, and soon afterwards returned to Calcutta.

### Naval Medical Service.

WILL the authorities who refuse to listen to medical journals take a hint from another source? The *Broad Arrow* says: "It is well known that for several years past there has been such a dearth of medical officers in the navy, that many seniors have been compelled to accept very subordinate positions; but as this was generally an alternative of going on half-pay, they were too glad in most instances to get employment at the sacrifice of dignity; and, so long as the appointment was a tolerably comfortable one, there has been but little complaint. Matters, however, seem to be coming to a crisis, as we notice that a second-class staff-surgeon and a medical officer of fourteen years' standing is now serving in one of the boys' training brigs—a lieutenant's command, and an appointment hitherto invariably held by a junior. Can we wonder that medical men are chary of entering a service where so little consideration is now-a-days shown either to their age or rank, and where, after long years of foreign service in a junior grade, they find themselves in a position even more subordinate than that in which they commenced life."

### Small-pox in Manchester.

DR. LEIGH, officer of health to the Corporation, has called attention to an outbreak of small-pox in the city. Dr. Leigh considers that the disease has been imported by one of the regiments which recently left Birmingham.

### Cremation.

IN our last we gave currency to a report that the body of Lady Dilke had been taken from England to Germany for cremation. It appears that there were good grounds for the report, for in the *Times* last week its Berlin correspondent gives particulars of the affair, at which he was present. He says: "The body of Lady Dilke, who died five weeks ago, in London, was burnt on the 10th inst., at Dresden. The ceremony was performed in the furnace recently invented for burial purposes by Herr Siemens, and the relatives of the deceased lady permitting strangers to be present, a large number of scientific men attended the experiment. When the company had complied with Herr Siemens' request to offer up a mental prayer, the coffin was placed in the chamber of the furnace; six minutes later the coffin burst; five minutes more and the flesh began to melt away; ten minutes more and the skeleton was laid bare; another ten minutes and the bones began to crumble. Seventy-five minutes after the introduction of the coffin into the furnace all that remained of Lady Dilke and the coffin were 6lb. of dust, placed in an urn. The brother-in-law of the deceased was present."

### Sanitary Panics.

WE observe that the sanitary inspector of St. Luke's has recently called the attention of the vestry to the fact

that he frequently finds articles of clothing and wearing apparel being made up in rooms where persons are suffering from fever and other contagious diseases. The sanitary inspector, in his report to the vestry, speaks of two cases in which ladies' corsets and dress "improvers" were being recently manufactured for a wholesale city house in tenements, or rather rooms, where persons were lying ill with scarlet fever. The sanitary inspector took the precaution of having the articles disinfected in the oven set up by the vestry for the purpose, but he says the operation was carried out very much against the inclination of the parties who were making up the corsets and dress "improvers."

Now, without at all desiring to discredit the statement of the inspector that disease may be thus propagated, or to discourage him and others in the exercise of every reasonable precaution, we feel apprehensive that the sanitary hobby is being ridden to death, and that there may be danger of making prudence ridiculous by over-precaution, if we may use such a phrase. It is quite open to debate whether a dress improver manufactured in an atmosphere of scarlatina, carried thence in the open air to a warehouse, stored there, perhaps, for months, brought again to a distance by a purchaser, and worn occasionally, as dress-improvers are wont to be used, could in any probability carry with it through all these stages the living scarlatinal germ. Whatever opinion may exist on such a point, there can be no doubt that the avoidance of such danger, if any there be, is, under present circumstances, practically impossible. No system of inspection nor any penal legislation could prevent the starving stitcher from taking in work when there was any to be got, and the merchant could hardly be expected to investigate the state of health of the workman's family before receiving back the finished article. The only thing which might be done would be to insist on disinfection if cases requiring it were detected. If the perils from such causes with which we are constantly threatened were as real and as alarming as we are told, we rather think that we should not be here to write of them, nor our readers to peruse them; universal depopulation would be inevitable.

### Cambridge University.

THE following appointments in the Medical Department of this University were officially declared on Thursday last:—

W. P. Hiern, M.A., St. John's, and R. Apjohn, B.A., Dublin, examiners for the first; Dr. Bradbury and J. N. C. Davies-Colley, M.C., M.A., of Trinity College, for the second; and Dr. T. Clifford Allbutt and Dr. C. J. Hensley, for the third M.B. examinations in the ensuing year.

J. Wood, F.R.S., F.R.C.S., and Christopher Heath, F.R.C.S., examiners for the degree of Master in Surgery during the ensuing year.

J. W. Ogle (M.D. Oxon.), Assessor to the Regius Professor of Physic during the ensuing year.

### Fallacious Evidence of the Senses.

WE were seriously assured the other day by a gentleman near the late explosion at Regent's Park that the earth rose up near him like an enormous wave of the sea. The

*Pacific Medical Journal* refers to the possibility of multitudes of observers being deceived simultaneously in regard to the apparent motion of trees and similar objects during the agitation caused by an earthquake. During the great earthquake of October, 1869, trees were seen, according to the testimony of observers, to rock so as to touch the ground with their lateral limbs, which were in reality entirely too high to render it possible that they should do so. Persons looking at tall chimneys observed the same phenomena. The explanation lies in the motion of the observer, which, concurring with that of the object, leads to a false impression on the visual organs.

There is an illustration familiar to every one of error of perception occurring in direct opposition to known truth. When one is seated in a train-car on a railroad, the train being stationary, the motion of a second train on a parallel track appears to be transferred to that in which the observer is seated. The moving train appears to be stationary and the stationary train to move; and this in spite of a perfect knowledge of the reverse possessed by the observer.

The rapid motion of a luminous body always deceives the eye by presenting the appearance of a line. Let any number of persons observe for the first time a stick lighted at the end twirled rapidly in a circle; they would all affirm with entire confidence that a circle of fire really existed.

#### Accident to a Medical Man.

On Wednesday morning last intelligence reached Cavan of the death of Dr. Cassidy, of Dowra. Deceased was riding a spirited horse, and the animal, becoming restive, threw him suddenly to the ground, causing instantaneous death. Dr. Cassidy was an ex-student of the Catholic University, and was one of the Irish Ambulance Corps during the late French war.

#### New Books for the Month, in Medicine, Surgery, and Science.

##### *Medical and Surgical.*

GALE (H. Stanley), *Clinical Atlas of Skin Diseases*. Coloured plates. Part I. 8vo. 3s. 6d.

Guy and Ferrier, *Principles of Forensic Medicine*. 4th ed. 12s. 6d.

Hull (Edmund C. P.), *The European in India; or, The Anglo-Indian's Vade Mecum*. 2nd ed. 6s.

Mair (R. S.), *Medical Guide for Anglo-Indians; being a Compendium of Advice to Europeans in India relating to the Preservation and Regulation of their Health*. 3s. 6d.

Moore (W. J.), *A Manual of Family Medicine for India*. 8s. 6d.

Muter (John), *An Introduction to Pharmaceutical and Medical Chemistry (Theoretical and Practical)*. 15s.

Thompson (J. A.), *Free Phosphorus in Medicine, with Special Reference to Neuralgia*. 7s. 6d.

##### *Science.*

Beckett (Sir Edmund), *Astronomy without Mathematics*. 5th ed. 4s.

Bullock, *Smaller Class-book of Modern Science*. 1s. 6d.

Clowes (Frank), *An Elementary Treatise on Practical Chemistry and Qualitative Inorganic Analysis, adapted for use in the Laboratories of Schools*. 7s. 6d.

Forbes (George), *The Transit of Venus. (Nature Series)*. 3s. 6d.

Marey (E. J.), *Animal Mechanism: A Treatise on Terrestrial and Aërial Locomotion, with 117 Illustrations*. 5s.

Rutley (Frank), *Mineralogy. (Murby's "Science and Art Department" Series of Text Books.)* 1s. 6d.

Tyndall (John), *Addresses Delivered before the British Association assembled at Belfast. With Additions*. 8vo. 3s.

Watts (Rev. Professor), *Atomism. Dr. Tyndall's Atomic Theory of the Universe examined and refuted*. 2nd ed. 4d.

#### Medical Society of the College of Physicians, Ireland.

THE general meeting of the Society was held in the College of Physicians on Wednesday last, the business in hand being the election of Council.

The names of the outgoing Council and six new candidates were submitted, as follows:—

Those marked \* were elected.

1. Atthill, Lombe, M.D., F.C.P.

\* 2. Benson, J. Hawtrey, M.D., F.C.P.

\* 3. Fitzpatrick, Thomas, M.D., Hy. F.C.P.

\* 4. Foot, A. W., M.D., F.C.P.

5. Gordon, Samuel, M.B., F.C.P.

\* 6. Grimshaw, T. W., M.D., F.C.P.

\* 7. Hayden, Thomas, F.C.P.

8. Johnston, George, M.D., F.C.P.

9. Kennedy, Henry, M.B., V.P.C.P.

\* 10. Little, James, M.D., F.C.P.

11. M'Clintock, Alfred H., M.D., L.C.P.

\* 12. Moore, J. W., M.D., F.C.P.

Cryan, Robert, F.C.P.

\* Finny, J. M., M.D., F.C.P.

MacSwiney, S.M., M.D., L.C.P.

\* Nixon, C. J., L.C.P.

\* Purser, John M., M.D., L.C.P.

\* Yeo, G. F., M.D., L.C.P.

#### Injection of Chloral into the Veins and Cellular Tissue.

M. COLIN has given in the results of a variety of experiments by the injection of chloral solution on goats, cats, rats, and rabbits. He summarises thus:—

1st. The injection into the veins and into the cellular tissues are equivalent.

2nd. Feeble solutions must be employed and the doses be carefully regulated.

3rd. Injection into the veins must be done very slowly and carefully.

4th. All veins near articulations must be avoided.

#### A Homœopathic Definition of a Drug.

It is not often that we can get out of the homœopathic writer anything in the way of an exact definition or any axiomatic statement of the views of his own craft, and we ought to be grateful when we are afforded any information which we can accept without doubt. The author of a recent American book on "The Science of Homœopathy" discusses with great apparent profundity the peculiar tenets of his speciality, which he honours with the name of science, and he wraps the hypotheses of that intangible art in such a cloud of incomprehensibilities that really the book reads as if the author was writing of something very

deep, and was profoundly versed in abstract science. He defines, for instance, a drug in the following phrase :—

"I hold that a drug, as a material substratum characterised by definite, individualising properties, is the product of the co-operation of two factors, the active, male, or inseminating life principle of the Cosmos and the telluric or passive female germ."

Whether or not the idea which the author desires to express is correct we cannot attempt to say ; but we only wish that we could give homœopathy credit for being "a material substratum characterised by definite properties."

### The Fish of Paradise.

A CHINESE fish, which is remarkable for its splendid tints, has been given this fanciful name ; its scales have all the colours of the rainbow, with vertical bands of yellow, red, and blue, and marked from head to tail with rays of changing colours ; the caudal fin is very large, and opens like a fan, resembling a peacock's tail ; the habits are peculiar. At the time of depositing the eggs the male makes a floating raft, furnished with air-balls, and made of a greasy substance which is secreted by the buccal membrane, and the eggs are deposited under cover of this raft during the incubation, which lasts three days. It never ceases replacing any injured or absorbed air-cells, and places these new cells ingeniously under the eggs, so forcing them upwards, and thus the upper part of the cell becomes dried, and it is through this the young escape. The male takes the greatest care of the young, and about 500 eggs are produced.

AN Odessa paper announces that the rinderpest is raging in Sebastopol and the neighbourhood, and that cattle are falling down dead in the streets.

THE Newcastle-on-Tyne Infirmary is to receive £25,000, and the Newcastle Dispensary £10,000, by the will of the late Mr. Hutchinson of that town. What will they do with it ?

DURING the past month 2,305 deaths were registered in the eight principal towns of Scotland, over thirty-two per cent. of which were caused by the zymotic class of diseases. Scarletina continues the most fatal of the epidemics, and is increasing.

THE subject of competition for the Hastings Gold Medal, value twenty guineas, offered annually by the British Medical Association, is announced for 1875 as "The Treatment of Aneurism," and the award will be made at the annual meeting of the Association in that year.

ANOTHER prosecution for defrauding an Irish Poor-law union by adulteration of milk occurred last week at Galway. From the evidence of Dr. Cameron, the county analyst, it appeared that the milk was watered to the extent of 60 per cent., and the magistrates, taking a strong view of the offence, unanimously convicted the defendants, and fined them £20 each, the highest penalty, together with 9 guineas costs.

### Election of Visitors of Examinations.

WE understand that within the last week the Branch Medical Councils for Ireland and Scotland have forwarded to the Executive Committee of the Medical Council the names of those gentlemen who have been recommended by the various medical authorities for the selection of the Executive Committee, to perform the duty of visiting the twelve licensing bodies whose examinations are to be inspected this year.

We announced last week that the Secretary of the Irish Branch Council had addressed to the governing bodies of the Irish medical authorities a letter requesting them to furnish the Branch Council with the names of those who were willing to act in that capacity. In accordance with that request, the names of the following gentlemen have been forwarded to the Irish Branch Council, and by them transmitted to the Executive Committee. From the College of Surgeons—Mr. Morgan, Dr. Mapother, Mr. Stokes, Dr. Corley, Dr. Croly, and Dr. Burton. From the College of Physicians—Drs. Lyons, Little, Foot, Hayden, Beatty, and McSwiney. From the University of Dublin—Dr. McDowel, Mr. Bennett, and Dr. Purser. From the Apothecaries' Hall—Drs. Charles Moore, O'Neil, Montgomery, and Collins. We hear that the Queen's University Senate, maintaining its attitude of hostility to the Medical Council and its recommendations, peremptorily refused to recommend anyone.

We think the governing bodies of some of the licensing bodies have gone beyond their authority in recommending any individuals when they were requested simply "to ascertain what members of 'their' body would be willing to undertake such duty and to furnish 'the Branch Council' with their names and qualifications ;" but we believe that, in so doing, they have taken a wiser course than that indicated by the Branch Council, and have, on the whole, made an excellent selection. The choice of visitors in this open and straightforward way will confer additional credit upon the verdicts which they may pronounce, and will confirm the good impression which the honesty of their judgments last year has created.

SEVERAL rather severe losses of cattle have lately been sustained by occupiers of low, marshy, undrained lands in different parts of Ireland, from vegetable poisoning. One outbreak of the kind has recently been successfully investigated in county Galway. It was distinctly proved that the cause of death was the poisonous effects of *Colchicum autumnale*, a plant peculiar to the lands above described. Twenty-three animals belonging to six or seven small tenants have succumbed.

WE are gratified to learn from the *Philadelphia Medical Times* that Dr. Buchanan, the sham diploma swindler of the so-called Philadelphia University, was arrested on September 16th, whilst on his way to the Eclectic College, on the charge of having caused the death of a Mrs. Isaac W. Vandegrift by an improper surgical operation. We must be thankful for any chance which rids society of such a harpy, and we venture to hope for him a long relief from

his infamous trade, and a favourable opportunity of mastering the mysteries of oakum-picking.

THE 102nd Session of the Medical Society of London commenced on last Monday, when the President, Victor de Meric, Esq., F.R.C.S., delivered an inaugural address, and also read a paper on "Ricord and his School." Dr. Theodore Williams related "Notes of a Case of Ulcer of the Stomach successfully treated by Nutritive Injections." For the Fothergillian Gold Medal, value twenty guineas, offered annually by the Society, the subject selected for competition in March, 1875, is "The Diseases of the Testicle and the Spermatic Cord;" for March, 1876, "On Cataract and its Treatment."

DR. MITCHINSON, coroner, presided last week at Welton, near Lincoln, at an inquest on the body of a labourer, found in a neighbouring field under suspicious circumstances. There was no evidence of violence, or other satisfactory cause of death, but in summing up the coroner suggested that heart disease might be the cause, or that deceased might have been seized with a certain spasm. Hypotheses are all very well in their way, but we think Dr. Mitchinson would have more faithfully performed his office had he ordered a post-mortem, and thus have obtained from medical evidence a satisfactory solution to the problem.

WHEN the Recorder of Dublin sat on Saturday to dispose of the business of the Licensing Sessions, Mrs. Edmundson, one of a deputation of ladies, handed in a memorial from the women in Dublin, pointing out the growing evils of intemperance in the metropolis, and praying the Recorder not to grant extensions of licences, but to do all he could to limit the number of public-houses. The Recorder replied that his private views agreed with those of the deputation, but he had to act on fixed principles. He granted no new licences, but allowed reasonable improvements to be effected in licensed houses. During this time the number of licences had been reduced from 1,200 to 800 in the city.

#### ARTHUR JACOB, M.D.

(From the *British Medical Journal*.)

By the death of Dr. Arthur Jacob, which took place on September 21st, at the residence of his son, at Barrow-in-Furness, at the patriarchal age of 85, the medical profession has lost one of its most remarkable men, and the Irish School of Surgery of the past generation one of its most brilliant lights and most respected members. From the year 1819, when, at the early age of 28, Dr. Jacob raised himself, by his discovery of the *membrana Jacobi*, to the highest rank among the anatomists of his day, until a few years since, when he retired from his public offices and professional duties with all the honour which his brethren could confer upon him, he never ceased to occupy a prominent position among the Irish representatives of medical science; and his connection with the Royal College of Surgeons in Ireland as a Councillor and as its Professor of Anatomy and Physiology is sufficiently recent to have left in the minds of his compatriots fresh memories of his great energy, unquestioned talent, and unsullied integrity.

Dr. Jacob, was the son, grandson, and brother of successive members of a family of surgeons who occupied the highest social and professional position in the Queen's County. His father was for many years surgeon to the chief infirmary in that district, and the youth of Arthur Jacob may be said to have been spent in the atmosphere of his profession. Leaving home in 1807, he became the pupil of Abraham Collis at Steevens' Hospital; and, after an apprenticeship of seven years, he graduated as M.D. in Edinburgh in 1814. After continued study in London and Paris, in the former metropolis under Sir Astley Cooper and Sir Benjamin Brodie, he returned to Dublin, and, having the surgical diploma of his own College, was chosen by Macartney, who was then Professor of Anatomy in the University, to be his demonstrator. In this position he acquired the character as an anatomical investigator, which he carried with him until the last years of his life. The fruits of much of his anatomical labour at this time found a place in the museum which Macartney sold to the University of Cambridge, and the remains of which are still there. Ceasing to be connected with the University, Dr. Jacob entered into conjunction with Graves, Marsh, Cusack, and Hart, and founded the Park Street School, which, though only continued for a few years, left behind it a name of which all its pupils are, to this day, justly proud. From this school, in 1826, Dr. Jacob was chosen Professor of Anatomy and Physiology in the Royal College of Surgeons in Ireland, where his fame followed him, and attracted to the school crowds of eager students and admiring listeners. From that day until 1869 he assumed and sustained the position of the leading mind, both in the educational working of its school and in its administration. With a constancy which was unshaken, a determination which knew no obstacle, and an integrity of purpose which justified all his acts, he devoted himself to the interests of the College, and left upon its policy for a quarter of a century the impress of his vigorous mind.

In the inception and consummation of the Poor-law and medical charities and the lunacy systems of Ireland, and in the successive attempts at medical reform which were brought before Parliament during that period, Dr. Jacob was a leading actor, always as the champion of the interests of his medical brethren and the protector of the integrity of his College; and, while the energy of his proceedings and the incisiveness of his speech necessarily clashed with the feelings of those who were opposed to him in opinion, there remains at this day but one sentiment—that of admiration for his talents and respect for his fidelity to his College. This latter and most engrossing characteristic of Dr. Jacob manifested itself peculiarly in the manner of his retirement from his Professorship and from his public life. Although he had continued to discharge his professional duties up to a few weeks before his final resignation with almost unabated vigour, and might reasonably have hoped to retain the emoluments of the chair for many years if he could be satisfied to occupy so important a position in consciousness than incapacity to do it justice was coming upon him, yet he no sooner felt the inevitable effects of age upon his mental and physical powers, than he at once retired from an office the duties of which he felt he could no longer fulfil with honour to himself or advantage to the school. Shrinking from the demonstration of friendly regret which he felt would be forced upon him if he were to make a regular public exit, he departed from Ireland, leaving behind him the scene of his well-loved labours and the sympathetic expressions of his colleagues and friends. The College, however, which had thrice elected him their President, refused to be thus prevented from expressing its regard for the man and gratitude for his services. A warmly phrased vote of thanks, an order for the execution

of his portrait, and a vote of one hundred guineas for the purchase of a testimonial gift, recorded the unanimous feeling of the Council; and the universal sorrow of the profession at his death gives witness that these kind feelings have not lost their force during the years which have since elapsed.

Of Arthur Jacob the worst which can be said is that those objects which were nearest his heart he loved "not wisely but too well." On more than one occasion the strength of his feeling and the vigour with which he went forward to his object gave him the appearance of intolerance in opinion and excessive zeal in action, and his unhesitating candour made for him antagonists whom a more cautious and disingenuous diplomatist would have conciliated.

## Medical News.

**Royal College of Surgeons of England.**—At the quarterly meeting of the Council, on the 15th inst., the Council considered a communication from the late Dr. Anstie, dean of a School for the Education of Ladies for the Medical Profession, requesting to know, amongst other matters, whether a list of gentlemen proposed for teachers would meet with their approval. The Council decided—That whilst they take no objection to the list of names submitted to them in the letter of the late Dr. Anstie as teachers in the proposed school, they are not prepared to imply a readiness to recognise a school which is incomplete, and respecting which they have so little information. It was resolved, on the motion of Mr. Simon—That it be an instruction to the Committee on Bye-laws to prepare for consideration of the Council a formula for a new bye-law under section 18 to define the privileges of the fellows and members respectively to hold meetings within the College, and to arrange the necessary provisions for holding such meetings. Other motions by Mr. Erichsen, Mr. Henry Lee, Mr. Gay, and Sir James Paget were deferred to a future meeting.

**The Drainage of Brighton.**—In reply to a recent article in the *Lancet* on this subject, Dr. Kebbell, medical officer of health for the Hove district, says, in reference to the ventilation of sewers: "I am very much mistaken if you will not find it the almost universal opinion of all who have paid any attention to the subject that the gases which escape from the open ventilators, when they are sufficiently numerous, and the sewers free from accumulations—which is the case with the Brighton intercepting sewer—though, doubtless unpleasant, are not injurious to health. Certainly, I have never either seen or heard of any cases of typhoid, or other fevers, which could be traced to this cause. The gases thus evolved are of recent origin, are freely mixed with atmospheric air while within the sewer, and are still further diluted and dispersed as they escape from the ventilators." He further thinks that the smell near the western outfall proceeds from the "lingering remains of filth of past years," very likely mixed up with decaying seaweed, which time alone will remedy, which was wrongly attributed by the people in the neighbourhood to the sewer ventilators. Still, with all due deference to Dr. Kebbell's explanations, we are disposed to believe that the new drainage scheme in this town is very defective, as we have it upon the authority of a correspondent who is in a position to know the real state of affairs that several cases of typhoid fever have recently occurred which can be attributed to no other cause than this.

**Scholarships at St. Mary's Hospital.**—St. Mary's Hospital offers several entrance prizes to students who select that institution for their education. These prizes are given by competitive examination at the beginning of the session. This October they have been awarded as follows: The scholarship in natural science to Mr. W. Pearce; the exhibition in natural science to Mr. F. A. Cox; the extra scholarship in natural science to Mr. C. M. Handfield Jones; the scholarship in classics and mathematics to Mr. H. N. Seager; the exhibition in classics and mathematics to Mr. C. M. Handfield Jones. The examiners were Dr. Cobbold, F.R.S., C. W. Heaton Esq., and the Rev. Dr. West, Head Master of Epsom College.

**University of Edinburgh.**—At a meeting of the University Court, on October 12th, an order of Her Majesty in Council was laid before the court, permitting Dr. J. Hughes Bennett to retire, on a retiring allowance, from the Professorship of Institutes of Medicine. Dr. William Robertson's resignation of the office of Examiner in Medicine was submitted. Dr. William M'Intosh, of Murthly, was appointed Examiner in Medicine, under the existing regulations, from the date of Dr. Robertson's resignation till the end of the present year. Dr. William Stirling has been appointed assistant to Dr. Rutherford, the newly elected Professor of Physiology. Examiners in the Public Health Department have been appointed. A Committee has been formed in London for the purpose of presenting a bust of Dr. Hughes Bennett to the University.

## NOTICES TO CORRESPONDENTS.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Dr. E. BELLIS is thanked for his note.

ON Friday evening the Quekett Microscopical Club will hold its first sessional meeting, at 8 p.m. Mr. R. P. Williams will read a paper "On Cutting Sections of the Eyes of Insects, and on a New Instrument for that purpose."

CLINICAL SOCIETY OF LONDON.—Opening meeting on Friday evening, at 8½ p.m. Mr. Carter, "On a Case of Vertigo, simulating Brain Disease, from Fatigue of Internal Rectus Muscle of Eye."—Dr. Southey, "On a Case of Scirrhus Cancer of Pylorus, with Encephaloid Infiltration of Left Lung and Supra-renal Capsules."

Dr. J. C. B.—Rather long. We will try to find room in our next.

Dr. A. G. B.—Received and handed to the gentleman referred to.

Dr. KIRBY.—The work was noticed in our issue of September 9th.

Dr. M., Torquay.—Thanks. A note has been made of the change.

Mr. P. S.—Had not been received at the time of our going to press.

TRAVELLING CONSULTANTS.—The followers of Aristotle are said to have been called peripatetics because they used to teach their science walking about. That science has received a new illustration during the past week or two, in London, in the august person of Prof. Lilley, who, with his wife, is "starring" the metropolis with several gaudily-painted caravans, one being his *domos*, another his surgery, another his consulting-room, in which the public is invited to enter for consultation with Dr. and Madam Lilley, of world-wide celebrity in the immediate cure of rheumatism, gout, &c. Prof. Lilley doesn't take permanent consulting-rooms, as he remits their cost to his patients by asking smaller fees.

COMMUNICATIONS, Enclosures, &c., have been received from Dr. Pavy, London. Mr. W. Adams, London. Dr. Lytleton Winslow, London. Dr. Déclat, Paris. Dr. Alexander Burness, London. Dr. Hansel Griffiths, Dublin. Mr. Blyth, London. Mr. Poole, London. Dr. Edgar, St. Louis. Mr. Squire, London. Dr. Hughlings Jackson, London. Mr. Lunn, Edgbaston. Dr. Ormsby, Dublin. Surgeon-Major F. R. Hog, Simla, India. Surgeon-General Gordon, C.B. Dr. Meymott Tidy, London. Dr. J. Drysdale, Liverpool. Dr. Berry, Wigan. Dr. E. C. Thompson, Omagh. Dr. E. Bellis, Much Woolton. Dr. Muter, Kennington. Mr. King, London. Dr. Crichton Browne, West Riding Asylum. Dr. Bradbury, Cambridge. Mr. W. J. Cox, Chipping Sodbury. Dr. O'Flynn, Drumshambo. Dr. Johnson, Kilkenny. Dr. Woodhouse, Westport. Dr. Mayberry, Kenmare. Dr. McNamara, Torquay. Dr. Barry, Lismore. Dr. Blennerhasset, Coolany. Dr. Cornelius, Mountrath. Dr. Crawford, Tandragee. Dr. Taaffe, Dublin. Dr. Wills, Bootle. Dr. Barker, Dublin. Dr. Beckett, Moneymore. Dr. O'Connell, Kilmallock. Dr. Bourns, Killala. Dr. Copeland, Florence Court. Dr. Bodkin, Arran Island. Dr. Kirby, London. Dr. Mason, Dublin. Dr. Forsyth, Culmore, Derry. Dr. Hyslop, Church Stretton, &c., &c.

## BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Osteology for Students, in 2 vols., Atlas and Text. Second Edition. By Arthur Trehern Norton, F.R.C.S. London: Baillière, Tindall, and Cox.

The Protoplasmic Theory of Life. By John Drysdale, M.D. London: Baillière, Tindall, and Cox.

On Functional Derangements of the Liver. By Charles Murchison, M.D., F.R.S. London: Smith, Elder, and Co.

Autobiography of A. B. Granville, M.D., F.R.S., in 2 vols. By his Daughter. London: King and Co.

Arædian Walks and Drives round London. By W. A. Johnson, M.D. London: Ward, Lock, and Tyler.

Compendium der Neueren Medizinischen Wissenschaften. Von Dr. Bernard Kraus. Vienna.

Handbook of Therapeutics. Fourth Edition. By Sydney Ringer, M.D. London: H. K. Lewis.

The Practitioner. El Anfiteatro Anatomico Espanol. Indian Medical Gazette. Boston Medical Journal. Philadelphia Medical Reporter. Allgemeine Wiener Medizinische Zeitung. Echo de la Presse Médicale.

## VACANCIES.

St. George's, Hanover Square, Dispensary. Resident Medical Officer. Salary, £150 per annum, with residence. Candidates must send copies of testimonials with their applications to the Secretary, Mr. Leash, 73 Park Street, London, W. (See Advt.)

Royal Free Hospital, London. Junior House Surgeon, for a term of six months. Board and residence provided. (See Advt.)

City of London Hospital for Diseases of the Chest. Resident Medical Officer. Applications to be addressed to the Secretary. (See Advt.)

Manchester Royal Lunatic Asylum. Assistant Medical Officer. Salary commencing at £120, with board and residence. Apply to the Resident Medical Superintendent, Cheadle.

North Staffs Infirmary, Harts-hill. Junior Resident Medical Officer, wife to act as superintendent of nurses. Commencing salary at £250. Board, &c., provided. Applications to the Secretary.

Bridgnorth Infirmary. House Surgeon. Salary, £100. Testimonials to be forwarded to the Hon. Sec.

Jersey General Dispensary. Resident Visiting and Dispensing Medical Officer. Salary, £120 per annum. Apply to the Rev. F. Le Feuvre, Jersey.

Carmarthen Infirmary. Resident Medical Officer. Salary, £100 per annum, with board and lodgings. Address Mr. Howells, King Street, Carmarthen.

Kent Lunatic Asylum. Medical Superintendent. Salary, £600 per annum, with unfurnished house, &c. Address the Clerk, 43 St. Margaret Street, Canterbury.

Kent Hospital. House Surgeon. Salary, £50, with board and lodgings. Applications to the Secretary at the Hospital, Canterbury.

Birmingham Free Hospital for Sick Children. Surgeon on the Staff. Honorary.

Central London Ophthalmic Hospital. Assistant Surgeon. Honorary. Belgrave Hospital for Children, S.W. Physician. Honorary.

## APPOINTMENTS.

ARMSTRONG, G. W. F., M.D., C.M., Medical Officer, &c., for the Castle-town Dispensary District of the Castletown Union, co. Cork.

FRASER, A. D., M.B., C.M., Medical Officer of Health for the Castle Ward Rural Sanitary District, Northumberland.

GARD, W. J., M.R.C.S.E., Junior Surgeon to the Royal Albert Hospital, Devonport.

HAMPTON, G. A., M.R.C.S.E., Resident Medical Officer to the Lambeth Infirmary, Prince's Road.

KERR, E. W., M.B., C.M., Medical Officer for the Kinlough Dispensary District of the Ballyshannon Union, co. Donegal.

KERR, N. S., M.D., C.M., Medical Officer for the Christchurch District of the Parish of St. Marylebone.

M'KENNICK, J. G., M.D., C.M., F.R.C.P. Ed., F.R.S. Ed., Professor of Physiology at the Edinburgh Royal Veterinary College.

POUNCEY, W. E., M.B., C.M., an Assistant Medical Officer at the Union Infirmary, New Bridge Street, Manchester.

RITCHIE, A., M.D., Parochial Medical Officer and Sanitary Medical Officer for Cathcart, Renfrewshire.

SCOTT, H. M., L.R.C.S.I., L.K.Q.C.P.I., Admiralty Surgeon for Achill, co. Mayo.

SMITH, H. B. L., M.B., C.M., M.R.C.S.E., House Surgeon to the Dorset County Hospital, Dorchester.

SMYTH, F. H., M.D., Extraordinary Physician to the Cork Fever Hospital.

STEVENS, F. G., M.R.C.S.E., Physician's Assistant at the General Hospital, Bristol.

SWAIN, E., M.R.C.S.E., L.R.C.P. Ed., Medical Superintendent of the Three Counties Asylum at Arlesey.

TURNER, R., M.D., Resident Medical Officer to the Infirmary and Dispensary, Newport, Monmouthshire.

WADDILL, J. C., M.D., an Honorary Medical Officer to the County Dispensary, Norwich.

WELSH, J., M.D., L.R.C.S.I., Medical Officer for the Ballyshannon Dispensary District of the Ballyshannon Union, co. Donegal.

WILLS, THOMAS, M., F.R.C.S.I., L.K.Q.C.P., &c., Honorary Surgeon to the Bootle Borough Hospital.

## Marriages.

BADCOCK-GRIFFITHS.—On the 6th inst., at the parish church, Upper Standon, Beds, John Henry Badcock, M.R.C.S.E., to Rebecca Elizabeth, only daughter of Thomas Griffiths, of Stanwell Moor, Staines.

BARNES-SNELL.—On the 15th inst., at St. Mary's, Stoke Newington, Edgar G. Barnes, M.D. Lond., of Eye, Suffolk, to Emma Elizabeth, third daughter of the late James P. Snell, of Holloway.

HOPKINS-BOWIE.—On the 15th inst., at St. George's, Campden Hill, W., Thomas Fay Hopcroft, M.R.C.S.E., to Elizabeth Thurburn, daughter of the late William Bowie, Esq., of Edinburgh.

REYNOLDS-NOTT.—On the 14th inst., at St. Mark's, Kennington, John Reynolds, L.R.C.P., M.R.C.S., to Caroline Harriet, daughter of William Francis Nott, M.R.C.S., of Kennington Park, Surrey.

## Deaths.

BLAKE.—On the 13th October, at Lorne Villa, Downend, near Bristol (late of Taunton), James Dore Blake, M.D., aged 69.

SMALE.—On the 7th October, G. E. Smale, M.R.C.S.E., of Wellington Road, St. John's Wood, aged 45.

VESEY.—On the 8th October, J. Stewart Vesey, M.D., of Belle Vue, Magherafelt, aged 59.

WILSON.—On the 8th October, Frederick Wm. Wilson, M.R.C.S.E., of Forest Hall, Long-Benton, Northumberland, aged 80.

## Advertisements.

**MEDICAL.—WANTED, an ASSISTANT to the APOTHECARY PROFESSION of two or three years' standing, who understands the Compounding and Dispensing of Physician's Prescriptions.—Apply to ALEX. BRIN, Arinagh.**

**IRISH PRACTICE.—A Medical Gentleman can be secured in an easily worked Practice, realising at present £300 a year, but which can be immediately doubled. Good house, office, &c., at low rent. Satisfactory reasons for present incumbent leaving. Terms moderate.—Apply MEDICUS, 23 Ely Place, Dublin.**

**ST. GEORGE'S, HANOVER SQUARE, DISPENSARY, 59 MOUNT STREET, GROSVENOR SQUARE.—The office of RESIDENT MEDICAL OFFICER is vacant. Salary, £150 per annum, with residence. Candidates are requested to send in their applications, accompanied with testimonials, to the Secretary, Mr. G. H. LEASH, Jun., 73 Park Street, W., on or before SATURDAY, OCTOBER 21st, who will give all information required as to the position and duties. Every candidate must be a Member of the Royal College of Surgeons and a Licentiate of the Apothecaries' Company.**

**ROYAL FREE HOSPITAL, GRAY'S INN ROAD.—There is a vacancy for a JUNIOR HOUSE-SURGEON to this Hospital. Candidates, who must be Graduates in Medicine of one of the Universities, or Members or Licentiates of one of the Colleges of Surgeons of the United Kingdom, and registered under the Medical Act, are requested to send in their testimonials to the Secretary on or before WEDNESDAY, 28th OCTOBER. The appointment will be made for six months only, but the holder will be eligible for re-election. Board and residence are provided in the Hospital. JAMES S. BLYTH, Secretary.**

**CITY OF LONDON HOSPITAL for DISEASES of the CHEST, VICTORIA PARK.—The appointment of RESIDENT MEDICAL OFFICER is now vacant. Applications, accompanied with testimonials, to be addressed to the Secretary, at the office, 24 Finsbury Circus, on or before MONDAY, the 26th inst. WILLIAM JONES, Secretary.**

**CITY OF DUBLIN HOSPITAL, UPPER BAGGOT STREET.**

## Physicians:

HAWTREY BENSON, M.B. Univ. Dub., F.K. & Q.C.P.I., L.R.C.S.I.  
J. MAGEE FINNY, M.B. Dub., F.K.Q.C.P.I., Demonstrator Trinity College.

## Surgeons:

JOLLIFFE T. TUFNELL, F.R.C.S.I., Ex-Regius Professor of Military Surgery, and President Royal College of Surgeons.  
HENRY GRAY OROLY, F.R.C.S.I., L.K. & Q.C.P.I., Senior Demonstrator of Anatomy, Royal College of Surgeons.  
WILLIAM I. WHEELER, F.R.C.S.I., M.D. Univ. Dub., L.K. & Q.C.P.I., Demonstrator of Anatomy, Royal College of Surgeons.  
ARTHUR BARKER, L.R.C.S.I., Demonstrator Royal College of Surgeons.

## Ophthalmic and Aural Surgeon:

LOFTIE STONEY, M.D., F.R.C.S., Demonstrator of Anatomy.

## Consulting Physicians:

Professor ARJOHN, T.C.D., and CHARLES BENSON, M.D., Ex-Professor of Practice of Medicine, Royal College of Surgeons.

## Consulting Surgeon:

WILLIAM HARGRAVE, M.D., F.R.C.S.I., Ex-Professor of Surgery, Royal College of Surgeons.

## Consulting Ophthalmic Surgeon:

ARTHUR JACOB, M.D., Hon. T.C.D., F.R.C.S.I., Ex-Professor of Anatomy and Physiology, Royal College of Surgeons.

The WINTER SESSION commences in OCTOBER. The SUMMER SESSION commences in MAY.

Special Wards, under the care of Dr. LOFTIE STONEY, are appropriated for the reception of Ophthalmic and Aural cases, and a distinct course of Lectures on Diseases of the Eye and Ear (including Operations) is delivered, for which a Certificate is given.

There is a ward exclusively for Children, affording ample opportunities of studying the Diseases of early life.

Connected with the Hospital is an extensive daily Dispensary, at which the Pupils are allowed to perform the minor operations, and are rendered familiar with the details of Dispensary Management and the Art of Prescribing.

The "Purser Studentship," of £20 per annum (with apartment-), founded by William A. Purser, Esq., L.R.C.S.I., a former Pupil of the Hospital, is open to all Students through the medium of Competitive Examination, for which a special Certificate is given, if merited, and numerous Medals and Prizes are awarded in Medicine, Surgery, and Ophthalmology.

The Drummond wing, for Fever and other Contagious Diseases, affords full opportunity for studying these branches of Medicine.

Instruction in Practical Pharmacy is given in the Compounding Department. Fee for Total Hospital Attendance, Twenty Guinea; Nine Months, Eight Guinea; Six Months, Six Guinea; Summer Three Months, Three Guinea.

For further particulars apply to Dr. WHEELER, Hon. Sec., 56 Pembroke Road, between Three and Four o'clock, or at the Hospital between Ten and Eleven o'clock a.m.

### CHOLERA: ITS *ÆTIOLOGY*, CONTAGIOUSNESS, AND TREATMENT.

By WM. BOYD MUSHET, M.B. Lond., M.R.C.P.,  
Late Physician to the North London Hospital for Consumption, formerly  
Resident Physician at St. Marylebone Infirmary.

#### *ÆTIOLOGY.*

OF the intimate cause and essential nature of cholera we are yet ignorant; nor does clinical or post-mortem observation appear to render its pathology more definite or satisfactory.

We observe a train of phenomena varying in character and intensity in particular cases; but the study of symptoms during life does not enlighten us as to the seat of the disease, or aid us in the establishment of rational principles of treatment. In fatal cases we discern no anatomical lesion, and beyond more or less marked pulmonary collapse and venous congestion, there is exhibited no appreciable alteration of the viscera. The flocculent ingredient giving rise to the characteristic rice-water, or "congee" evacuations, which has been supposed to contain some entity having an influence on the causation of cholera, was long since pointed out by M. Boëhm, of Berlin, to be merely the rapidly shed epithelium of the alimentary canal, and Dr. Hassall's minute microscopical examination of the blood, urine, epidermis, and clothes of patients failed to detect anything unusual. In like manner, the fungi and vibriones detected in the atmosphere, air passages, alimentary tube and discharges, have been also found in the larynx and contents of the intestines of healthy persons by Dr. Hassall, Mr. Rainey, and other investigators.

But many other diseases are characterised by like obscurity of origin, like negation of evidence on autopsy, though they have not demanded so much attention, owing to the infrequency of their occurrence, or to their being less deadly, or less rapidly fatal in progress. The stomach and intestines, liver, spleen, and other viscera

have been respectively considered to be most implicated or concerned in the evolution of the disease, the organ in question being conceived to undergo some vital or functional perversion in consequence of the action of a specific *materies morbi*. Many, as Mr. Grove, have ascribed this to spores or animalcules suspended in the atmosphere, or drinking-water, and Dr. Sansom has revived the opinion, as he holds that the cholera germ is *organised*; and that it *lives and grows and multiplies*. Mr. Grove maintained "that to some form of life (most probably vegetable) the principle of epidemic and infectious diseases is to be referred; that the predominant or governing influence is due to reproduction, and that it is during the exercise of the reproductive faculty of the poison germs that the phenomena of acute disease are manifested." Still more recently Dr. Déclat and other French physicians strongly support the "fungoid" theory; but, although this doctrine is attractive and plausible, it presents numerous fallacies, and is altogether undemonstrable, as I have already noticed. Others assign the disease to volcanic or electrical conditions, and deduce scientific inferences from the state of the atmosphere, which prove on analysis to be merely circumlocutory avowals of ignorance, though the meteorological observations of Mr. Glaisher—an epitome of which will be hereafter given—are of interest, as they hold out a hope, in the future, of throwing a light on the origin of the epidemic. Again, the disease has been deemed by some to be dependent upon malarious or miasmatic agency, to which the spleen is considered to be specially obnoxious. In support of this the spleen may undergo some functional change in cholera, as the blood presents considerable alterations (such as increase of its corpuscles and viscosity, and diminished and diffuent condition of its fibrin), over which fluid this organ is regarded to possess great and peculiar influence. According to Mr. Gray, the spleen regulates the *quantity* and *quality* of the blood; but after extirpation, which does not inconvenience the animal, the increase of blood is equally distributed over the whole system, so that the vessels contain more than under ordinary circumstances. Of course, the viscosity of the blood is mainly due to separation of its watery

constituents; but may not this viscosity be dependent (it is asked) on perverted action of the spleen failing to maintain hæmostatic equilibrium, and consequently favouring elimination of the thinner portions of the blood by the alimentary canal? If this theory be accepted, the analogy may be carried further, and cholera be regarded as a species of intermittent (Dr. Billing), the cold fit of which becomes developed, but it is not succeeded by the hot stage, in consequence of the concentrated or more subtle action of the malarious poison. The secondary fever, however, if collapse be recovered from, may be viewed as the analogue of the hot stage. Ague districts are said to be not particularly liable to visitations of cholera, though, if visited, the disease has been reported to rage with peculiar virulence; but such facts do not militate against the theory, as the diseases are presumed to be similar, not identical, in their mode of generation. But it is impossible to reconcile what has been observed relative to the origin and propagation of cholera with such a theory; there is complete absence of evidence in its favour; and lastly, the splenic derangement which is the effect of intermittents cannot be fairly, according to such a method of reasoning, considered, if it exist, as the cause of cholera.

Numerous authors maintain that the disease is *always* traceable to impurities in the water of the district; but this fails to explain its appearance or production under circumstances where the water has been avoided, or found free from noxious ingredients, and although there is great truth, there is probably not the whole truth in this view, as water only proves a source of cholera under certain conditions, which will be more fully alluded to. Even Dr. Snow, the great advocate of this theory, was unable to explain all circumstances connected with the visitation by the aid of the water theory alone; yet it must be admitted that in several instances, as during the memorable outbreak near Golden Square, in 1854, and in East London in 1866, the introduction of impure water into the system was almost mathematically demonstrated to be the chief, if not the sole agency in the development of the disease. Very many other examples might be quoted in proof of the connection between impure water and the prevalence of cholera, and there is also truth, if not the whole truth, in the remark of the late Dr. Dundas Thomson, "that where cholera was most fatal in the metropolis the water supply was most impure." Nevertheless, concerning the water supply in relation to cholera, I hold the summary derived from evidence furnished to the General Board of Health in 1854 to be equally true—viz., "that there is no sufficient proof that impure water acts specifically in generating cholera, or, in other words, that it is the specific cause of the disease." This conclusion should carry great weight, when it is borne in mind that Drs. Hassall, Dundas Thomson, and other competent men were specially engaged in the investigation, and that Dr. Hassall concludes "that microscopical examination of the different waters obtained from houses visited by cholera—though denoting impurity as a characteristic feature—throws no special or direct light upon the production of the epidemic." To revert to earlier writers, Dr. Roupell, in his Croonian Lectures for 1833, regards "the primary cause of cholera to be an affection of the nervous system, and that the immediate result of this is an irritability of the lymphatic portion of the vascular system, occasioning increased fluid discharges." He thought the discharges in cholera are similar to the contents of the lymphatic vessels, and that a local impression on the nervous centres of the abdomen which supply the viscera produce the symptoms of collapse without impairment of intellect, cold sweats, pulselessness, &c. Such a view was originally entertained by many Indian practitioners nearly half a century since, and Mr. Sedgwick likewise labours to prove that cholera is the result of functional disorder of the sympathetic nervous system, excited through the medium of the alimentary canal, chiefly of the stomach. Dr. Sansom also affirms that cholera is due to *irritation*, not *paralysis*, of the abdominal sympathetic.

Dr. Parkes, however, says, the leading idea he has formed of the nature of cholera is not only that it is primarily a disease of the blood, as has been generally surmised, but that the changes induced in the function of respiration directly consequent on the alteration of the blood are the proper and distinctive symptoms of the disease. The alterations of the pulmonary functions, therefore, enter into his definition of true cholera, and for the purpose of expressing this decisively he has ventured to employ the term "*algide cholera*" as a synonym for "*cholera gravior*" of Orton and others. He thinks the cause of cholera to be a septic agent, or *materies morbi*, rather than a result of atmospheric changes.

Dr. Snow thought the disease due to some sort of structure, most likely a cell, though not to be recognised microscopically, any more than that of variola. He also held that the poison must be swallowed, or introduced into the alimentary canal, most frequently from water. Notwithstanding these views, he thought if the blood were poisoned the disease would be ushered in by febrile or other general symptoms. The diminished volume and thickened state of the blood accounted in his mind satisfactorily for all the symptoms of cholera, and he thought the blood was not poisoned, except in cases of consecutive fever. He adduced the fact of temporary restoration of the patient by diluting the blood with a weak saline solution as an additional proof that the circulating fluid is not poisoned in collapse.

Not to enlarge too much on this part of the subject, I will merely quote Mr. Headland (*Lancet*) in evidence of the contrariety of views entertained by different members of the profession. This gentleman thinks cholera is a blood disease, probably an affection of the corpuscles, as animal heat, &c., is impaired, which function physiologists attribute to the corpuscles; and, again, collapse may occur (he says) before thickening of the blood occurs from exudation of the liquor sanguinis. He is a non-contagionist, but thinks there is no connection between cholera and diarrhoea.

The most reasonable presumption appears to me to be that cholera is dependent on a septic animal poison, which is similar to the view held by the late Mr. Herra-path, of Bristol. I do not conceive it essential that this poison be organised, or a specific cell, as odorous matters, such as musk, snuff, &c., though in a high state of volatility, are neither gaseous, fungoid, nor animalcular, and yet they are decidedly capable of exerting physiological effects. It is a commonly received opinion amongst Continental physicians that *ochleris* and want of cleanliness will produce the disease—circumstances most favourable to the production and evolution of decomposing animal matters. Again, experience demonstrates that cholera appears in greatest virulence in localities where there exist cesspools, gullies, drains, foul sewers, poisoned water supply, and putrefactive exhalations. It is highly probable that emanations from these sources enter the system through the alimentary (or pulmonary?) mucous membrane. The effect of such septic matters is to produce disturbance of the functions of the gastro-intestinal tract and other phenomena of cholera, varying in degree according to the intensity or peculiarity of the poison; for as each province or district has its own source of decomposing materials, we must admit, I think, a plurality of choleraic poisons; and observation tends to confirm such doctrine, as at the same period of the same epidemic the disease appears to be milder in certain localities and certain individuals, for which habit and constitution alone fail to account. Under this head I may call attention to the diarrhoea and intestinal derangements often witnessed amongst students exposed to the putrid atmosphere of the dissecting-room, and to the production of serious diarrhoea in irritable subjects after indulgence in high game and other partially decomposed food, of which healthy persons partake with impunity, and obviate the effects by the antiseptic properties of their gastric and intestinal juices.

The septic poison produces a modification in the functions of the alimentary tract, manifesting itself in diarrhoea.

and vomiting, the symptoms differing much according to the potency and speciality of the operating cause and the constitutional powers of the patient, as the poison will of course act more energetically on those subjected to exhaustion, privation, or excess. I believe, then, that the causes constantly exist, and are in operation, which may produce diarrhoeal symptoms, but why at particular intervals these symptoms should merge into cholera is at present a mere speculation, and may ever remain a mystery to man. The causes contributing to the production of cholera must have existed ever since mankind has been congregated in masses, although we have no authentic evidence of the appearance of the scourge until the present century. Mr. Curtis, surgeon in Sir Edward Hughes's squadron, in 1782, gives a graphic account of a disease which, according to Dr. Roupell, was undoubtedly cholera, and from the description there cannot be much doubt of the correctness of the opinion. It may be found in the Madras Reports. Most authors, however, date its appearance at Jessore in 1817, and at Sunderland, in England, in 1831; but, from the foregoing, such a chronology is incorrect; and many hold that the black death of the middle ages and various epidemics of plague may have been true cholera visitations.

**Meteorology.**—Mr. Glaisher, in his Report on the Meteorology of London (Report of the Committee for Scientific Inquiries in Relation to the Cholera Epidemic of 1854), states that during the prevalence of the disease there was undue height of the barometer, the temperature was above the average, and there was less range of temperature than usual; the atmosphere was calm, still, almost stagnant, thick and misty—thin in high places, dense in low. The rainfall was unusually small, there was deficiency of positive electricity, and the ozone was very deficient, almost undetectable in low districts. These conditions are favourable to the accumulation and concentration of poisonous matters in the atmosphere, and of course augment the potency of their action. They depend on physical causes as much beyond the control of man as the variation in weather, temperature, and season, and either constitute or intensify the "epidemic influence." In 1866 Mr. Glaisher noticed the meteorological characters were different from those of former cholera periods. Thus, between midsummer and the end of the quarter, the atmospheric pressure was remarkably low, and the temperature of the air also low, night and day, except in September, when the nights were warm. The daily range of temperature was small, and there was abundance of rain everywhere. The air was in almost constant motion, frequently blowing much heavier than usual. Nearly all the circumstances were directly opposite to those mentioned as being present on previous visitations. They probably aided in checking its wider extension. One of the most remarkable atmospheric phenomena was the prevalence of a peculiar blue mist, which was generally present, extending from Aberdeen to the Isle of Wight, of the same blue tint everywhere. This increased in intensity through the telescope and in density during the fall of rain. It did not decrease when the wind blew moderately, but did when a gale was blowing, increasing again on its subsidence. Mr. Glaisher does not know the nature of this mist, but it had not been noticed since the cholera period of 1854, which points to a possible connection. Dr. Leith Adams, however, disputes the relation between this blue mist and the epidemic, as he has observed it in almost every quarter of the globe when cholera was not known to exist within thousands of miles.

I assert that cholera must be regarded as diarrhoea maligna, or diarrhoea assuming a malignant type under certain almost unknown cosmical conditions, which can only be defined as "epidemic influence," "epidemic constitution," or, as M. Guérin prefers, "medical constitution;" though, with the exception of Mr. Glaisher's observations, we are utterly ignorant whether such factor be meteorological or telluric.

(To be continued.)

## REPORT ON SYPHILIS.

By C. R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.,  
Senior Physician to the Metropolitan Free Hospital.

DR. THIRY, OF BRUSSELS, ON SYPHILIS.

OPINIONS as to the treatment of syphilis vary very greatly indeed, to the great misfortune of medical science; nor is there, of course, any way of reconciling the various opinions emitted by men of experience; so that the best plan, perhaps, is to let each speak for himself, so that bystanders without any opinion definitely made up may be enabled to arrive at some conclusion.

Dr. Thiry, of Brussels (*Presse Méd. Belge*, Nos. 97 and 98, 1874), has published a clinical lecture delivered at the Hôpital Saint-Pierre, of Brussels, in the month of June, which contains some new ideas on treatment.

Every day, says M. Thiry, you see numerous cases of syphilis at my clinique; they are always grave, and often present difficulties of diagnosis which I must enable you to surmount, so that shortly, when you shall be left to your own judgment, you shall not experience difficulties, or commit those gross errors which I am in the habit of remarking every day. On a question so clear as syphilis there are so many opinions diametrically opposed and contradictory to one another that I cannot too much warn you against the fashionable errors of the day. It has often been repeated that syphilis is not to be seized in its aspects, that it is variable in its forms and alterations; but this is not the case; certainly its forms may change according to the gravity of the disease, the tissues it attacks, the more or less advanced period at which it has arrived, but at the bottom of these alterations which are apparently so distinct we find its characteristic, which is the syphiloma, or initial induration, which takes place, without fail, after chancres, which end in their special way, that is, without having by energetic treatment been reduced to the condition of a simple suppurating wound.

We shall not to-day dilate further on these considerations, which, besides, you know well, for I hasten to pass to the examination of the fact which is to make the subject of this clinical lecture, and in which we shall find all the elements which prove the truth of the principles I teach.

A woman, aged 26, of lymphatic temperament, a laundress by trade, mentions that she had a lover who impregnated her, and communicated syphilis to her. About 22 months ago this woman was delivered of a weakly infant, which died six weeks after birth. Since her labour, which was a normal one, the patient says she has not enjoyed good health. Twelve months subsequent to the event she felt pains in the abdomen, and these were so strong that she was forced to enter the Hôpital Saint-Jean. She was attacked with peritonitis, and by means of fitting treatment, she was cured. Some time after her leaving, abscesses formed around her organs of generation, and seven weeks ago she was attacked with headache of violent character, with frontal neuralgia and facial tic, for which she went again to be prescribed for at Saint-Jean. But during her residence in that establishment, there appeared an eruption on her body, and syphilis having been recognised, she was sent to the Hôpital Saint-Pierre. (We presume this is the Venereal Hospital of Brussels.)

As you will notice, the face of this patient is pale, decomposed, and denotes terrible pain—that is, the syphilitic facies; she is chloro-anæmic, has lost her menstruation for six months, her muscles are flaccid, her skin and mucous membranes are pallid. The patient hangs her head and avoids the light. On examination of her eyes, we find the ocular palpebral conjunctivæ hyperæmic, with evident peri-corneal circle; the transparency of the cornea is troubled by a serous exudation formed in the anterior chamber; the iris of the two sides is irregularly deformed, angular, and discoloured; vision is difficult and painful; in a word, there is very intense double iritis.

The sub-occipital glands and those in the groin are hard. The whole body of the patient is covered with a papular eruption of a red coppery hue; by pressure the papule is made to project, and we notice the induration and the pearly-white tint characteristic of syphiloma.

The symptoms which we have just past in review, and above all, the existence of the syphiloma, permit us to diagnose syphilis. On examining the genital organs of this woman, we perceive on the external aspect of the right labium, as on the internal part on the left of the commissure, the traces of a chancre, and we feel clearly the induration; there is a true syphiloma there. Whatever this patient may tell us in the history of her antecedents, we dare to affirm that the chancres date from the epoch when she says she had abscess in this region. These pretended abscesses were chancres, and the infection dates from that period, for if it were otherwise, and if the infection, as she says, had been concomitant with her pregnancy, or twenty-two months back, how could we explain the long period of time elapsing between the contamination of the chancre and the appearance of syphilis. That would be impossible, unless we were to make inadmissible hypotheses. Again, that which we see and touch is quite in opposition with the information furnished to us, which proves the little weight you ought to place on subjective phenomena. Patients, remember, deceive you voluntarily or involuntarily; at other times, when you seek to influence their replies, they confirm all you demand of them. The general symptoms are, first of all, intense headache, which we may refer to the violent inflammation of the eye, then the chloro-anæmia produced by the penetration of the syphilitic principle into the blood, and, lastly, the syphilitic rash.

This woman, before her entrance into hospital, has been treated by the iodide of potassium; it was evidently not for the purpose of combating the syphilis that this drug was administered, but very probably for the neuralgia of which the patient complained. Iodide of potassium does not possess any influence on a patient whilst under the influence of syphilis; it is only when the syphilis has disappeared that we can destroy by the iodide of potassium the poisonous effects of the mercury, if it have been administered abusively.

Do not forget this, that iodide of potassium can do nothing against true syphilis; and if it is generally regarded as efficacious in the tertiary accidents of syphilis, it is because these accidents, called tertiary, frequently are foreign to syphilis, and that they have been beforehand tried unavailingly by mercury.

All the facts, and they are numerous, which I have been able to observe, confirm me in this opinion. It would be strange indeed, if what I assert were not founded on truth, that mercury should cure the accidents called secondary, and should fail against tertiary accidents, which proceed from the same principle, whilst the iodide of potassium, by a not less strange singularity, should be powerless against the secondary accidents (1st period of syphilis) and should cure tertiary accidents (2nd and 3rd periods of the same syphilis). This pretension surpasses the limits of reason, and facts well diagnosed do not confirm it. (a)

Besides, mercury administered in an intelligent way scarcely ever produces the disastrous effects that persons are fond of attributing to it.

Incontestably, it is anti-syphilitic treatment to which we ought to have recourse, that alone can make the grave symptoms we have before our disappear. In vain would you prescribe iodide of potassium, or launch yourselves

in the dangerous path opened before you by certain reformers by administering chromic acid, preparations of iron, and tonics; you would certainly fail, and the disorders would become so great that the life of the patient might be rapidly endangered by this.

But if mercurial preparations alone are capable of curing this patient, you ought not to forget that she is the subject of certain lesions, and notably of iritis, which would end in annoying results if you did not assist your treatment by specifics, by auxiliaries capable of preserving the iris from the consequences which the inflammatory accidents you persevere in it may provoke. The iritis is certainly syphilitic; but this syphilitic condition is complicated with inflammatory phenomena; these last ought to be combated in a peculiar manner, and at the same time as you are treating the diathetic state.

We then order for this woman four pills a day, composed of two milligrammes of corrosive sublimate and one centigramme of gummy extract of opium. Each of these pills is to be swallowed with a glass of the decoction of sarsaparilla.

Every second day a friction for a quarter of an hour with Neapolitan ointment is to be made on the external aspect of the limbs, and after every two frictions a tepid starch bath is to be taken.

A reparatory animal diet, in small rations at a time, with two meals a day, is ordered for the patient.

To combat the iritis at once, we prescribe a collyrium, composed of five centigrammes of neutral sulphate of atropia and ten grammes of water. Three or four drops of this will be instilled into the eyes thrice daily, in order to dilate and relax the iris; besides, some frictions with mercury and belladonna will be made around the orbit.

This treatment, regularly followed out, has given the best results. In a few days the accidents connected with the iris were passed, and, a month afterwards this patient was completely transformed, and commenced to come out of the profound cachexia into which she had fallen, and regain strength and tone. One would say that mercury had brought new life to this organism, by opposing itself energetically to the invasion of the destructive syphilitic poison.

On the 10th of August the iritis was quite cured, and vision was excellent. The rash was gone, as well as the occipital and inguinal enlarged glands; we might have supposed her cured, if she had not complained of vague pains in the limbs, and maintained a certain amount of weakness and anæmia, due probably to the fact that her menstruation had not yet returned.

To cure this state, we suppress the pure mercurial treatment, which has been carried on till this date, and replace it by the following:—

- 4 grammes of iodide of potassium,
- 3 milligrammes of cyanide of mercury,
- 15 grammes of syrup of codeia,
- 100 grammes of distilled water.

A tablespoonful for a dose, morning and evening. We have always found this preparation do well after a long course of mercury, and especially when vague pains remain, which make us suppose there is nervous disease.

At the same time, to remedy the anæmia, and cause the reappearance of menstruation, we prescribe pills of lactate of iron and extract of aloes, the patient to take one at each meal, and to eat more abundantly of nourishing food.

Sitz-baths every morning, in which two handfuls of common kitchen salt are dissolved.

By this medication we expect to modify rapidly the constitution of our patient, to dissipate her pains, and regularise her functions.

The next lecture of Dr. Thiry is rather a startling one, and will, we doubt not, astonish many besides ourselves, for, in it, he actually denies that mucous tubercles are a part of syphilis. For our part, if there be any lesion pathognomonic of syphilis to our eyes, it is precisely the mucous tubercle, and this is the received opinion in the profession. But let us hear Dr. Thiry.

In a lecture reported in the *Presse Méd. Belge*, No. 38,

(a) It will be seen by readers of the *MEDICAL PRESS AND CIRCULAR* who have attended to the lectures of Dr. Alfred Fournier, lately published therein, how completely at variance Dr. Thiry's ideas of the value of the iodide of potassium in tertiary lesions are with those of Ricord and Fournier. I may add that I entirely endorse the views of Fournier on this point, and think Dr. Thiry completely in error in failing to recognise the incalculable value of the iodide in gummy tumours.—C. R. D.

he says that among the affections which are generally looked upon as syphilitic, and which yet have nothing in common with the chancre or with syphilis, we shall cite that villanous disease, so frequent, and to which the name of *mucous tubercles*, *mucous pustules*, *Nat* and *humid* have been given.

He adds : In what I am about to say on this subject, as it is against received opinions, and is even in opposition with the opinion of *savants* of the highest distinction, I would pray you to fill your mind thoroughly with the considerations into which I am about to enter, and, in order to convince you of their truth, to follow carefully the curious case which calls up this subject, and which we are about to consider together.

Mucous tubercles have nothing in common with syphilis, whatever practitioners may think, who, until now, have considered them as being, as may be said, a pathognomonic symptom of this diathesis.

Anatomically and pathologically, they present none of the essential characters of syphilis ; they are formed by round or oblique tumours, resulting from the hypertrophy of the follicles of the skin and subcutaneous cellular tissue ; they are not at all the consequence of a very active inflammation, for most generally their colouration is dark brown, the venous capillaries are more developed than the arterial capillaries ; they have no trace of syphiloma, and in place of being hard, are soft, easily depressible, without any pearly aspect.

Mucous tubercles are discrete, or united in more or less considerable groups ; eroded at their summits, the mucous tubercles secrete a serous liquid, which only becomes irritating when it accumulates in the interstices we meet in those parts where numerous mucous tubercles are seen to collect. The liquid thus accumulated decomposes and gives forth a fœtid odour of peculiar kind ; sometimes the erosion of which I have spoken may become ulcerated, and then form a parchment-like plate, or acquire a characteristic hardness ; then complications have arisen in the mucous tubercles, about which I shall have to speak immediately.

If you incise a rather voluminous mucous tubercle, you find all the elements which constitute the derm, and besides these, an interstitial plasma. The sebaceous follicles have larger proportions ; all these elements, besides being exaggerated, are gifted with a greater consistence, which, as I have told you, is not so hard as the syphiloma. You will notice that I insist greatly on this point.

Mucous tubercles are primarily developed, and constitute the sole alteration remarked : they never alter the constitution of the patient who is the subject of them ; on the contrary, if art do not interfere, they multiply, take large proportions, and may inoculate the neighbouring parts, or even propagate themselves over different parts of the body.

I have noticed a case where almost all the skin was covered with them, from the intervals between the toes up to the scalp. The patient was repulsive, and gave forth an odour of extreme fetidity. The individual we are about to examine is nearly in this same condition. Almost always, in similar cases, by merely looking at the evil aspect of the patient, syphilis is diagnosed authoritatively. Nevertheless, it is not the case, and the rapidity with which we make, by the simplest plans, such affections to disappear, would prove most clearly, if we had not to assist our opinion the analysis of anatomy and pathology, which does not reveal to us any of the elements necessary to constitute a syphilitic manifestation.

Mucous tubercles may appear consecutively, and at the same time as another disease ; in other words, the cause which presides over their development acts simultaneously with other causes ; each of them produces the effects which it brings with it, and these effects are associated and confounded. If we are not forward, we attribute them often to one sole cause, which is either the chancre

poison or the syphilitic poison, an absolutely false way of looking at it, as I have told you.

In our case, mucous tubercles are associated with urethritis, or blennorrhagia. The blennorrhagia is then looked on as the cause of mucous tubercles, and as these are gravely accused of syphilitic poison, persons cite these facts as a proof of the syphilitic nature of blennorrhagia.

At another time, mucous tubercles exist along with chancres ; sometimes even these chancres are engrafted upon mucous tubercles. This is the contagious virulent mucous tubercle, the secondary symptom *par excellence* of authors. Indeed, if you did not know the peculiar nature of the mucous tubercle, you might commit this error.

You would inoculate, for instance, the matter of an ulcerated mucous tubercle with chancre virus, and you will necessarily obtain a chancre, and as you would take the mucous tubercle, without thought of the existence of the chancre, for a manifestation of secondary character, you would evidently conclude, with certain very distinguished authors, that syphilitic accidents, called secondary, reproduce themselves by inoculation under the form of chancres. Besides, you would be the more convinced that you were right, that in many cases the chancres inoculated on the mucous tubercles become hard, and then certainly end in syphilis.

Lastly, nothing prevents mucous tubercles from being developed during the duration of syphilis ; because a patient is attacked with this latter diathesis, it is no reason that he should be sheltered from mucous tubercles. It thus happens that persons do not remark the distinction we are endeavouring to draw, and the mucous tubercles are more and more considered as a manifestation of syphilis, and as asserting its existence.

This opinion is, however, erroneous. You will have the proof of this on carefully observing the effects of the treatment you make use of. If you force these kind of patients to rigorous care and cleanliness, you will see the mucous tubercles disappear in a few days, whilst the urethritis, the chancres, and the syphilis will resist, sometimes for long, your therapeutic efforts.

Most generally, mucous tubercles are seated on the genital organs : in the male they are seen on the lips of the meatus urinarius, on the gland, the prepuce, or scrotum ; in the female they are in groups, and close together, along the labia majora, the mons Veneris, at the orifice of the vagina, and even on the cervix uteri.

In the two sexes they are seen most frequently at the margin of the anus, at the internal and upper part of the thighs, and the inguinal regions ; then on the navel, in the axillæ, at the commissures of the lips, the nasi, at the commissures of the eyelids, on the forehead, behind the ears, at the nape of the neck, at the summit of the head, on the tongue, tonsils, or between the toes or fingers.

In general, the mucous tubercles grow with facility wherever the skin is abundantly furnished with cutaneous follicles and sweat ducts, and where it is similar to the mucous membrane.

We shall consider the mucous tubercle as having a quite peculiar essence, that is, a morbid type, very villanous, it is true, but not at all grave, and rapidly cured. Irritating simple causes do not produce them any more than the chancre virus, or the syphilitic poison. The conditions which we have ascertained as most commonly presiding over their appearance are the following—great want of cleanliness, and the abuse of connection between two persons equally uncleanly.

You will very frequently observe, gentlemen, that mucous tubercles are contagious, and propagate themselves even on the patient himself who is affected.

In another clinical lecture, contained in No. 39 of *La Presse Médicale Belge*, M. Thiry completely pronounces against the so-called *dualistic* theory of syphilis, held at present by the great majority of scientific writers in Paris and elsewhere.

His evidence against dualism is given from the consideration of a case of phagedæna of the glans penis, accompanied by phymosis, which was followed by syphilitic rash. This fact M. Thiry supposes to be a testimony against the idea that the soft sore is quite foreign to syphilis.

But M. Ricord, and all writers of the French school, have remarked that phagedæna occasionally, although very rarely, attacks the hard or non-suppurating sore, and, of course, phymosis in such a case may be conjoined with the true chancre.

It is singular indeed that in the two instances we have cited from Dr. Thiry such striking deviations from the ordinarily received opinions should have to be chronicled from a man of experience.

But in venereal disease scepticism and doubt have been a chronic malady, and it is reserved, we fear, for a future generation to have some catholicity as to the pathology and treatment of syphilis. We avow ourselves, in the meantime, partisans of the dualistic theory.

### CASES IN PRACTICE.

Reported by JOHN W. MARTIN, M.D.,

Assistant-Surgeon Mayfield Factory Dispensary, Portlaw, &c.

*CASE.—Aortic Patency—Paralysis of the Muscles of the Right Side of the Face, and of the External Rectus of the Left Eye, with Strabismus and Double Vision—History of Chronic Rheumatism—Recovery.*

JOHN SHEA, æt. 53, by occupation a beamer in the factory. (Notes taken February 23rd, 1874.) He gave the following as the history of his case: He has been delicate for the past sixteen years, and dates the change in his health from a severe attack of rheumatic fever, which he had about that time, with subsequent paralysis of the right arm, the use of which he did not recover for the space of twelve months. Four years ago he first felt a sharp pain in the region of the heart and epigastrium, accompanied by flatulence, alkaline eructations, constipation, loss of appetite, and other dyspeptic symptoms of such a marked character that no attention was directed to the state of the heart itself, the treatment being confined to that usual in cases of dyspepsia. He was compelled to give up work, and has never since been able to resume it for any length of time, as he has rarely been free from pain.

In the commencement of January, 1874, whilst in the Union Hospital in a state of convalescence from a sharper attack than usual of the dyspeptic symptoms, he noticed one morning that he saw everything double, shortly afterwards he felt great pain in the right side of his head and the whole of that side of his face; the surface was swollen, and tender to the touch; the right ear became painful, and quite deaf; the pain was much increased by speaking. He suffered from complete loss of rest.

He had been so long complaining, the dyspeptic symptoms were of such an intractable character, and he had acquired such a reputation for making the most of whatever was the matter with him, that these symptoms were overlooked, or not believed in, and he was discharged from hospital. Returning to Portlaw, and presenting himself for treatment, my attention was directed more closely to his case by my father, who noticed the strabismus of the left eye.

The following were the symptoms I noted: Complexion sallow, and general appearance one of great delicacy and weakness; greater fulness about the right side of the face than the left; the muscles flabby, and marked by a want of tone; the mouth presenting the usual appearances in cases of facial paralysis, the right angle drooping, the left slightly drawn upwards; pain is felt in the articulation of the lower jaw on the affected side, rendering it difficult to open his mouth; the tongue protruded weakly, and to right side; his articulation hesitating, slow, and indis-

tinct, the more decidedly so when induced to speak more rapidly than usual; when speaking for any time feels the voice greatly fatigued. Owing to the difficulty experienced in opening his mouth, I was unable to obtain a satisfactory laryngoscopic examination. There is paralysis of the velum palati on the right, and the tip of the uvula is arched towards the same side; there is internal strabismus of the left eye (the right being unaffected), the external rectus being paralysed, as evidenced by the impossibility of rotating the eye outwards beyond a point midway between the median axis and outer canthus; there is some tenderness to pressure, with increased tension in the eyeball, and the ophthalmoscope reveals well-marked congestion of the retina as compared with the unaffected eye.

*State of the Heart.*—Rhythm and force normal; no increase in the area of dulness; first sound distinct, second sound lost; a short, sharp, rough murmur, heard best at the apex, immediately preceding the impulse and first sound, at a point one and a half inches below, and to the right of the left nipple; this murmur was heard softer in character at a point mid-sternum, opposite the articulation of the 4th rib.

The second sound was replaced by obstructive and regurgitant murmurs, the first heard most distinctly in the third intercostal space on the right margin of the sternum; the latter in the second intercostal on the same side. The obstructive or systolic murmur is propagated along the arch of the aorta, and into the right carotid artery. The murmurs at the base of the heart are not well heard to the left of the sternum. He had two severe attacks of hæmoptysis in June, 1873, but none since. Never had any cough or pulmonary symptoms. Tongue clean; his bowels costive; liver normal; walks well; finds no difficulty in standing with his feet placed together and his eyes closed.

*Treatment.*—Placed him on 1-16th of a gr. of hyd. bichloridi, twice daily, in mixture.

March 5th.—General appearance much improved; swelling in the right side of the face diminished; less pain in the articulation of the lower jaw; tone of muscles improved; tongue deviates only slightly to the right; left eye recovering the power of outward rotation.

March 13th.—Still improving, with the exception of persistent headache in the right parietal region, by which he is prevented from resting at night.

R Potass. iodidi, ʒi.;  
Hydrarg. bichloridi, gr. i. (in solution);  
Syrupi, ʒi.;  
Aqua ad ʒiij. M.

One tablespoonful to be taken three times a day.

March 16th.—Free from headache; paralysis of the eye quite gone; general appearance greatly improved.

March 21st.—The swelling in the right side of the face has almost disappeared; the muscles recovering power; general expression improved. Phonation and articulation stronger and more distinct; some changes observable in the condition of the heart from that noted in the first examination. The basic murmurs more pronounced; the regurgitant murmur formerly heard in the 3rd intercostal space on the right margin of the sternum now heard at the articulation of the 4th rib on the left side with the sternum. Instead of the single murmur, before described as heard at the apex, there now exists a well-marked double murmur; in its first part this murmur in part precedes, in part accompanies, the impulse and first sound; in its second half it follows the first sound and impulse, occupying the first half of the period of rest. This murmur is propagated in the direction of the lower edge of the sternum, gradually reaching its maximum intensity in the first intercostal space, near the articulation of the 5th rib. Mid-sternum, opposite the same point, a short sharp clicking murmur is heard accompanying the impulse and first sound, most probably due to pericardiac friction.

His general appearance greatly improved. Treatment continued.

March 31st.—Improvement permanent.

R. Potass. iodidi,  $\mathfrak{z}\text{i}$ .;  
Liq. cinchonæ,  $\mathfrak{z}\text{i}$ .;  
Tr. cinchona,  $\mathfrak{z}\text{ss}$ .;  
Syrupi,  $\mathfrak{z}\text{i}$ .;  
Aquæ ad  $\mathfrak{z}\text{xij}$ . M.

Two tablespoonfuls to be taken three times a day.

R. Oleum morrhua,  $\mathfrak{z}\text{viij}$ .

One tablespoonful to be taken at night in a little warm milk.

The subsequent history of the case was one of steady improvement, and restoration to a state of comparative good health.

In remarking upon the symptoms presented in the foregoing case, two hypotheses present themselves to account for them :—

The first, one of embolism, of some one or other of the smaller arteries at the base of the brain, in favour of which we have the existence of old-standing valvular disease of the heart. The second, that of rheumatic inflammatory changes in the sheaths of the affected nerves, at their intracranial origin. For my own part, I am inclined to regard the latter as the more satisfactory.

Embolism would, I think, have produced a more serious and decided train of symptoms. The limited and bilateral character of the paralysis, the portio dura of the 7th and the 9th, or hypoglossal, on the right side, and the 6th on the left, being the only nerves involved, decidedly impress me with the idea that the paralysis had its origin in some affection of the nerves themselves rather than in the central organ, the brain. This opinion appears to receive additional support from the immediate and favourable result of a mercurial course of treatment, which we know exerts a powerful controlling influence over most forms of local inflammatory congestions, and further, we know that these latter are not at all unusual where the rheumatic taint exists, as it did in this case.

## STUDENTS' COLUMN.

### LESSONS ON PRESCRIPTIONS AND THE ART OF PRESCRIBING. (a)

By W. HANDSEL GRIFFITHS, Ph.D., L.R.C.P.E.,

Licentiate of the Royal College of Surgeons of Edinburgh, Honorary Member of the Ontario College of Pharmacy, Librarian to the Royal College of Surgeons in Ireland.

#### LESSON VII.—(Continued).

##### PHARMACOPŒIAL GROUPS.

###### ACETA.

Acetum.  $\mathfrak{z}\text{i}$ .—ii.  
Acetum Scilla.  $\mathfrak{M}$  xv.—xl.

###### AQUÆ.

The dose of all the aquæ is  $\mathfrak{z}\text{i}$ .—ii., except *Aqua Laurocerasi*, the dose of which is  $\mathfrak{M}$  v.—xxx.

###### CONFECTIONES.

The dose of all is  $\mathfrak{z}\text{i}$ .—ii., except *Confectio Opii*, which is gr. v.—xx., and *Confectio Scammonii*, which is gr. x.—xxx.

###### DECOCTA.

The dose of all is  $\mathfrak{z}\text{i}$ .—ii. except—

P. Jalapæ Compositus.	
P. Rhei Compositus.	} gr. x.— $\mathfrak{z}$ i.
P. Tragacanthæ Compositus.	
P. Amygdalæ Compositus, $\mathfrak{z}$ i.—ii.	

## SPIRITUS.

The dose of all spirits is  $\mathcal{M}$  xx.— $\mathfrak{z}$ i., with the following exceptions:—

S. Camphoræ. $\mathcal{M}$ x.—xxx.	} $\mathcal{M}$ xxx.— $\mathfrak{z}$ ii.
S. Ætheris.	
S. Ætheris Nitrosi.	
S. Arnoracæ Compositus.	

## SUCCI.

The doses of these are as follows:—

S. Belladonnæ. $\mathcal{M}$ v.—xv.	} $\mathfrak{z}$ i.—ii.
S. Conii. $\mathcal{M}$ xxx.— $\mathfrak{z}$ i.	
S. Hyoscyami. $\mathfrak{z}$ ss.— $\mathfrak{z}$ i.	
S. Scoparii.	} $\mathfrak{z}$ i.—ii.
S. Taraxaci.	
S. Limonis. $\mathfrak{z}$ i.—iv.	
S. Mori. <i>ad lib.</i>	

## SYRUP.

Dose of all is about  $\mathfrak{z}$ i., except—

S. Ferri Iodidi.	} $\mathcal{M}$ xxx.— $\mathfrak{z}$ i.
S. Scillæ.	
S. Chloral. $\mathcal{M}$ xxx.— $\mathfrak{z}$ ii.	
S. Rhei.	} $\mathfrak{z}$ i.—iv.
S. Sennæ.	

## TINCTURA.

The tinctures may thus be grouped, according to their dosage:—

T. Aconiti; T. Belladonnæ; T. Cannabis Indicæ; T. Cantharidis; T. Capsici; T. Iodi; T. Nucis Vomica; T. Veratri Viridis; T. Zingiberis Fortior.	
---	--

*All*  $\mathcal{M}$  v.—xx.

T. Colchici Seminie; T. Digitalis; T. Ferri Acetatis; T. Ferri Perchloridi; T. Laricis; T. Lobelia; T. Lobelia Ætherea; T. Opii; T. Scillæ; T. Stramonii; T. Sumbul; T. Tolutana.	
---	--

*All*  $\mathcal{M}$  v.—xxx.

T. Assafoetida; T. Benzoini Composita; T. Camphoræ Composita; T. Castorei; T. Chloroformi Composita;	
--	--

T. Croci; T. Guaiaci Ammoniata; T. Hyoscyami; T. Myrrhæ; T. Opii Ammoniata; T. Sabinæ; T. Valerianæ Ammoniata; T. Zingiberis.

*All*  $\mathcal{M}$  v.— $\mathfrak{z}$ i.

T. Aloes; T. Arnica; T. Aurantii; T. Aurant Recent.; T. Buchu; T. Calumbæ; T. Cardamomi Composita; T. Cascarilla; T. Catechu; T. Chirata; T. Cinchonæ Composita; T. Cinchonæ Flavæ; T. Cinnamomi; T. Conii; T. Cubebæ; T. Ergotæ; T. Gallæ; T. Gentianæ Composita; T. Jalapæ; T. Kino; T. Krameria; T. Lavandulæ Composita; T. Limonis; T. Lupuli; T. Quassia; T. Quiniaz; T. Quiniaz Ammon.; T. Senega; T. Serpentaria; T. Valeriana.

*All*  $\mathcal{M}$  xxx.— $\mathfrak{z}$ ii.

T. Sennæ.  $\mathfrak{z}$ i.—iv.  
T. Rhei (*Purgative*).  $\mathfrak{z}$ iv.— $\mathfrak{z}$ i.

## TROCHISCI.

From one to six of any of the lozenges may be given, except lozenges of ipecacuanha, of which not more than three should be administered.

## VINA.

The following are the doses of the wines:—

V. Colchici.	} $\mathcal{M}$ x.—xxx.
V. Ipecacuanhæ ( <i>Expectorant</i> ).	
V. Opii.	
V. Aloes.	} $\mathfrak{z}$ i.—ii.
V. Rhei.	
V. Ferri.	} $\mathfrak{z}$ i.—iv.
V. Ferri Citratis.	
V. Ipecacuanhæ ( <i>Emetic</i> ). $\mathfrak{z}$ iii.— $\mathfrak{z}$ vi.	} $\mathfrak{z}$ iv.— $\mathfrak{z}$ i.
V. Antimonialis ( <i>Emetic</i> ).	
V. Quiniaz.	

In the foregoing summary I have included those substances which are contained in the recent "Additions" to the Pharmacopœia. I will not now speak of *accumulation* and *toleration* of drugs, as I have elsewhere treated in detail of these important subjects.

The following quotation from an able article in the *Medico-Chirurgical Review*, (a) will form a fit conclusion to the present lesson: "Doses are the most relative things in the world. It must be confessed that a certain maturity of mind and boldness of action are requisite to escape from the slavery of pathological entities and essences, and to allow the apparent exigencies of the case before us to be our sole guide. That constitutional bashfulness which is called 'caution,' which habitually delights in small ways, and which is half-afraid of the instruments it uses, should practise other arts than the art of medicine. A wise courage is the physician's watchword."

(To be continued.)

## Luxation of the Tendon of the Tensor Vaginæ Femoris.

DR. ARDENNET, of Foissac, reports the following case: He was recently consulted by a labourer, who stated that, while engaged in the field at labour which required great efforts on the part of the inferior extremities, he suddenly experienced an acute pain in the right knee. On examination, the most apparent symptom was the acuteness of the pain when the right leg was moved. The leg was flexed, and with some difficulty the author succeeded in extending it. A small tumour was then found located behind and above the external condyle of the femur, which was very tender on pressure, and connected with a cord which extended downward and from within outward. The author thereupon made the diagnosis of luxation of the tendon of the fascia lata, produced by extraordinary muscular effort, and after several attempts succeeded in replacing it in its normal position. This was accomplished by exerting pressure from without inward with the thumb of the right hand while the left sustained the limb. As soon as the tendon recovered its normal position, anterior to the external condyle, the patient experienced complete relief, and could walk without pain or difficulty, and on the following day returned to his customary duties.—*New York Medical Journal*, Sept., 1874; from *Journal de Thérap.*, 1874.

## Hospital Reports.

### CHARING CROSS HOSPITAL.

#### *A Supplementary Spleen.*

AN interesting case of farcy was admitted into the above-mentioned hospital last week, which terminated fatally, from exhaustion, in a few days. Only one abscess in the left axilla required opening. The post-mortem revealed the following: The body was well nourished generally; a few pustules on the upper part of the thorax; both lungs in the first stage of pneumonia; on the right side there were old pleuritic adhesions; the heart sound was empty; the lining of the aorta was covered with atheromatous patches; liver normal, also the spleen, and, strange to say, there was a supplementary spleen, the size of a walnut; the kidneys were congested, especially the right, which was larger than the left, and weighed considerably more; the lymphatic system generally was in a state of turgescence, but there was no appearance of pus in any of the joints or internal organs.

### RICHMOND HOSPITAL, DUBLIN.

*Scald of the Glottis followed by Œdema—Tracheotomy—Recovery.*

(Under the care of PROF. STOKES.)

Reported by MR. C. N. GWYNNE, Acting House-Surgeon.

ERNEST MCGUINNESS, æt. one year and eight months, was admitted on the 5th of August last, at 10.40 p.m., suffering from intense dyspnoea. The mother gave the following history:—

About 4.30 p.m., the same day, she had occasion to leave the child alone for a few moments, and on returning found it in the act of endeavouring to drink hot water out of a kettle that lay near the fire. She lost no time in bringing the child to the Richmond Hospital, which was close at hand, where it was seen by the resident pupil on duty. There being then nothing calculated to excite immediate alarm beyond slight evidence of recent scalding about the lips, the mother was desired to take the child home and to watch it closely, and if she noticed the mouth becoming swollen, or any difficulty of breathing to lose no time in bringing it back. Whether these injunctions were in part disregarded, or that the dyspnoea set in suddenly, which was the account given, it is hard to say; be it as it may, when the child was brought into hospital, at 10.30 p.m., it was suffering from the most intense dyspnoea, the lips and inside of the mouth looked white and scalded, the face wore a cyanotic hue, and the pulse was so weak as scarcely to be perceptible.

Being at once convinced that the case had passed the stage when calomel and antimony or other antiphlogistic treatment could be of any service, and that the only chance lay in prompt operative interference, I lost no time in despatching a messenger for Prof. Stokes, and in the meantime applied hot stupes assiduously to the child's throat, and, while watching closely the progress of the case, made every preparation to perform an operation at a moment's notice should it be necessary. After waiting anxiously for somewhat more than half-an-hour the messenger returned with the report that Prof. Stokes was not at home, so, observing that the case was becoming more and more urgent, and that no time was to be lost if an operation was to be of any use, I determined to open the trachea myself.

Placing the child on a table in a room in which a fire had been previously lighted, and being ably assisted by Mr. Murphy and two of the resident pupils, Mr. Cosgrave and Mr. McDonnell, I cautiously opened into the trachea, below the isthmus of the thyroid gland, which was plainly recognised and drawn up out of the way. There being no tube small enough, I introduced a portion of a No. 5 French gum-elastic catheter; but this becoming much

clogged with mucus, I subsequently removed it and introduced a No. 9 in its stead. There was no hæmorrhage of any consequence during the operation, and after it was over the child experienced immediate relief, and the pulse gradually regained strength.

Aug. 6th, 2 a.m.—Pulse 142; had the greatest difficulty in keeping the tube free; was obliged more than once to apply my mouth to it and extract the mucus. Subsequently I made use of a small-sized catheter, having a thread twisted round it, and this, kept immersed in a weak solution of salt and water, I passed in frequently, taking care barely to exceed the limits of the tube. This I found a most efficient method of liquifying and removing the gummy tenacious mucus that constantly adhered to the sides of the tube.

10.30 a.m.—Seen by Prof. Stokes, who pronounced the case to be doing well. The patient was able to swallow a few teaspoonfuls of milk.

8.30 p.m.—The tube continues to be kept clear, in spite of a slight cough, thanks to the untiring and almost unremitting attention of Mr. Cosgrave. Pulse 162.

Aug. 7th, 11 a.m.—Is beginning to breathe a little through the mouth. In the afternoon of this day Prof. Stokes removed the tube. As there was considerable inflammation around the wound he did not think it advisable to close it, but thought it better to allow it to close up by granulation from the bottom.

Aug. 9th.—Still suffering from a bad cough. Linseed-meal poultices applied to chest.

Aug. 13th.—Cough better. Bread-and-water poultice applied to wound, which still continues somewhat sore and inflamed. Some air still passes through the opening. From this time forward until the day of its leaving hospital, the child, which had become much reduced, gradually recovered strength, and the cough, which at one time caused considerable apprehension, daily abated in severity. On the 27th inst. the opening into the trachea ceased to transmit air.

Aug. 31st.—Allowed to be removed home to-day. The wound has almost entirely closed up, the appetite is good, and all trace of cough has disappeared. I may add, as a matter of the last importance in such cases, that during the whole time that the wound in the trachea remained patent, especial attention was directed to keeping up an even high temperature in the room where the patient was, and this, further favoured by the uncommon warmth of the weather at the time, conducted in no slight degree to the successful issue of the case.

### GENERAL HOSPITAL, DOUGLAS, ISLE OF MAN.

#### CASES IN HOSPITAL PRACTICE.

By THOMAS A. WOODS, M.R.Dub., &c.,

ONE of the great advantages of a hospital is the confidence we obtain by experience in remedies we find recommended, and a knowledge of new properties and actions of measures suggested by circumstances; and I think it is the duty of every man who holds a hospital appointment to give to his brother practitioners any case which, although not startling from its magnitude or novelty, may be instructive. The following may, to some of your readers, rank in this category.

I was called on the 17th of September last to see a young woman of well-developed *physique*. She had always previously been healthy, but during that day she had been seized with epileptiform convulsions. She was quite unconscious, frothing from the mouth, tongue partly protruding, and face and neck congested, rolling her head from side to side. She had œdema of the legs, irregular and rapid pulse, involuntary ejection of the urine, and general fulness of body. She was unmarried, and I had no history of her case. Suspecting pregnancy, I made an examination, and I found my suspicions correct, and that she must have nearly arrived at her full time. The practice a few years ago would no doubt have been to take away twelve or fourteen ounces of blood, so threatening seemed the danger of congestion in

the head. I, however, was content to order twenty grains of chloral hydrate every fourth hour, and I had all impediments to free action of the heart and lungs removed. During the night she had nine similar attacks, with partial consciousness in the intervals. However, in the morning she had lost all bad symptoms, and lay perfectly tranquil and composed. The next evening I was hastily summoned to my patient, whom I found standing on the floor of her room with the body of a fœtus hanging from the vagina, the head alone being retained. I had her immediately placed in bed, and I brought away the child, which was dead, and I experienced much difficulty afterwards in getting the placenta, through an irregular contraction of the uterus. This woman perfectly recovered, and is now as well as usual. I believe the convulsive attack preceding the labour was brought on by mental worry and fear—the nervous shock so dangerous and depressing in these unfortunate cases, and for this reason I think a sedative and soothing plan of treatment more likely than any other to lead to a successful issue under these unhappy circumstances.

Another case was that of a man suffering from organic stricture of the membranous portion of the urethra. He was brought into hospital last week enduring much agony, the passage of the urine being entirely prevented. He was 45 years of age, a car-driver by occupation, and constantly exposed to hardship and change of weather, which induced in him a mode of life the reverse of temperate. He could ascribe no cause for the sudden and total inability to pass water. It generally came away almost *guttatim*, but now it had ceased altogether. I could not introduce any sized catheter, even the finest. I tried what effect could be produced by the warm bath, sedatives, antispasmodics, &c., in facilitating the introduction of the instrument, but all failed. I then applied four leeches to the perinæum, and shortly afterwards, to the great relief of my patient, as well as to myself, I slipped in with ease a small sized catheter, which I had to no purpose endeavoured to introduce before. I think this success is worth recording; certainly, if the same proceeding is attended with the same pleasant feeling to others as it was to me, I shall not have written in vain. I will just add that a stoppage of the water in a few days afterwards caused me again to introduce the catheter, but no urine passed, although the instrument entered the bladder. I found on withdrawing it that the eye was choked up with aropy mucus, and the same consequence foiled a second attempt. However, making the man strongly try to urinate as I brought away the catheter, the water passed in a rather good stream, and for the present he has been relieved.

#### NORTH LONDON CONSUMPTION HOSPITAL.

(Under the care of Dr. C. R. DRYSDALE.)

##### *Somnambulism.*

EMMA HALL, aged 25, married nearly five years, no children nor miscarriages. For three months past she has been affected with somnambulism, especially if worried in the day. Twice or thrice in the week she gets out of bed, asleep and walks about the room, or gets into the passage, quite without consciousness. Her husband gets up and brings her back to bed without her knowing anything of it. Great headache comes on after it. Has been subject to hysterical fits during the last seven years. She used to walk in this manner in her sleep as a child, but this left off at twelve years of years. She affirms that her sister used to walk about in the same way. Three of father's family were insane, and were in asylums. None of mother's family have been insane. Sometimes she cries out in her sleep, and frightens everybody. Menstruation regular; no dysmenorrhœa.

Dr. TILT has been elected an honorary member of the Obstetrical Society of Philadelphia.

## The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 23, 1874.

#### EXAMINATION v. CURRICULUM.

THE extremity of opinion into which the abuses of the lecture and certificate system have driven many thinking men in our profession is that which might reasonably have been anticipated—i.e., that all pre-examination teaching should be voluntary, and that the examination itself should be the sole test of proficiency. Some of the licensing bodies, and notably those subsidized by the State both in London and Dublin, have proceeded, to a certain extent, upon this hypothesis, and are conferring qualifications upon a very deficient curriculum, declaring in defence that their examinations are sufficiently searching to make it absolutely impossible that an ignorant man could pass their portals. The question has therefore arisen in a practical form how far it is possible to construct a system of examination and to select examiners who will inevitably filter out the lazy, incompetent, or superficially educated candidates without imposing too high a standard of education on students whose talents are mediocre in quality, and without checking too severely the demand for admission to the profession. This is undoubtedly the coming question amongst medico-educational topics, and any light which experience throws upon it may be gladly received. Like the costly war of opinion and experiment between ironclads and big guns, we are entering on our contest between shrewd examiners and sharper grinders—the examiners endeavouring to barricade the gates of the profession, and being every day out-generaled by knowing and hard-working besiegers, who somehow or other do manage to get their men within our outworks, no matter what vigilance we meet them with.

In the English Pharmaceutical Society this game of chess is aptly illustrated. The Society has all the powers which Parliament could give it for the control of pharmaceutical education; it has a monopoly, and is, therefore, able to fix its own requirements, and it has a sufficient supply of candidates to make it quite independent of either monetary considerations or of any difficulty in satisfying the demand for educated chemists. Its Council seems to have done its best to frame a careful system of examination, and has confided it to competent hands, and it evidently uses its powers of exclusion against the incompetent without any mercy.

The first examinations under the new regulations took place, we observe, on the 9th inst., when two candidates presented themselves for the Major, and both failed; seven for the Minor, of whom five failed; and twenty-seven for the Modified, of whom thirteen failed.

Pharmaceutical examinations were held also at Edinburgh. Seventy-five candidates presented themselves for the Minor examination, of whom twenty-eight passed. Four who offered themselves for the "Modified" all passed.

Out of 115 examinés, 67, or nearly 60 per cent., were rejected, so that we may assume that neither the examiners nor the Society are afraid to do their duty.

Nevertheless, it appears that, in the absence of some compulsory curriculum, the Court of Examiners finds itself unable to keep out the ignorant without running the risk of excluding also a class of fairly educated men with moderate talents. Mr. Giles, of Clifton, who delivered the inaugural address, and distributed the prizes, bewails the prevalence of the "cramming" system, and asserts that it can only be met by the establishment of a compulsory curriculum. He says:—

The object of examinations is to exclude the unqualified; the scarcely disguised object of "cram" is to pass the unqualified through. Whether at our own school, or elsewhere, a term of one, two, or three months is totally inadequate for the preparation which pharmacy requires of its disciples, and utterly insufficient to afford that amount of qualification which public opinion demands. The cramming system does this, and is working so much mischief to *bona fide* education that it is the bounden duty of all honest men to unite in stamping it out. Its operations are wide-spread; wherever examinations prevail (and where do they not?) this noxious parasite springs up and poisons the air. In the universities, the professional colleges, the army, the navy, the civil service—everywhere the evil is rampant, and, it must be admitted, triumphant; and everywhere the wail of examiners, cheated with open eyes, goes up. To show that our examiners are not more easily imposed upon than others, I will read a short extract from an article upon "cramming" in a popular periodical:—

"The disgusted examiner gradually recognises that he is not conversing with George Griffin, jun., but with Dr. Varnish, M.A., &c., who speaks all languages, knows something of everything, and is growing rich apace by preparing young gentlemen for the civil and military service of their country. Mr. Griffin is there in the body, certainly, with pink ears and heated forehead, and his preceptor is as undoubtedly absent; but, nevertheless, the examiner cannot but feel that all his efforts are as thoroughly baffled as if the young man were a medium, and Dr. Varnish held him under some as yet unknown mesmeric influence. There is no getting at the lad's real brain, no finding out what he will be when, at no distant date, he shall have forgotten Varnish and all his works. As it is, that subtle instructor of youth has armed him at all points; he is a pattern pupil, and has absorbed exactly such information, and no more, as will help him through the ordeal before him. If caught tripping on one subject, he is comfortably bolstered up on all the rest, and as the defeated examiner grudgingly sends in his name at the top of the list, he is forced to acknowledge with a sigh that Varnish is a very clever fellow."

This graphic sketch conveys the painful impression that the newly-developed idea of universal examinations, which was doubtless expected to give encouragement to education, has had a contrary effect; that it has diverted attention from education to fix it upon examination—that it has overwhelmed the substance in its own shadow, and invested the shadow with the semblance of reality. The

pharmaceutical crammer is equal to the occasion; he tempts unwary youths with the flattering assurance that he will qualify them for the examinations in five weeks! and forthwith commences a digested course of unmeaning jargon, of which, I am told, the following is a specimen, "Three—one—five—, catch 'em alive; one—two—three, out goes she"! and this, by some inscrutable property of association, is said to enable the candidate for pharmaceutical honours to remember (till next examination day) the respective constitution of carbonate of magnesia and carbonate of zinc! but for all useful purposes, for all that makes knowledge convertible into power to be utilised in after-life, he is as ignorant as he was before.

We commend these observations—the enunciation of actual experiences—to the Senate of the London University and the Queen's University in Ireland, and we ask them to consider whether the examinations which they have carried out with so much care, and of which they are justly proud, do really effect any other purpose than to admit all the well-ground men and winnow out all the practical workers whose knowledge is in their eyes and on their fingers' end, and not on the outside of their brain. The speaker goes on to say:—

The obvious remedy is the establishment of a compulsory curriculum of education at recognised schools as a condition of examination. The principle is generally adopted elsewhere; it prevails at the old universities, at the medical schools, at the more recently established Veterinary College, and in the Continental schools of pharmacy: and there is no feature of our system which our Continental brethren view with so much disapproval (not to say contempt), or regard as such a fatal blot upon its efficiency, as the absence of a prescribed course of study. I cordially agree with them, and speaking here without official reserve, and without the fear of implicating the higher powers (I may also say, without much fear of offending them), I express my deliberate conviction that a compulsory curriculum must sooner or later be adopted, and the sooner the better.

As far as the Pharmaceutical Society is concerned, it thus stands confessed that examinations are an unreliable test of proficiency, and, if that conclusion be a sound one, the sooner our educational reformers set themselves to work at the other end of their task and endeavour to make sure that pre-examination teaching shall be—what it has never been—genuine and practical, the sooner the difficulties of medical education will receive a permanent solution.

#### A PURE WATER SUPPLY.

It will not be denied that a pure water supply is of paramount importance to our town populations. It would be difficult to exaggerate the importance of the question of a wholesome water for domestic uses, in very many ways, and we therefore desire to draw special attention to a recently published pamphlet, entitled "A Microscopical Examination of Certain Waters submitted to Jabez Hogg, and a Chemical Analysis by Dugald Campbell, with Introductory Notes by Samuel Collett Homersham, Member of the Institute of Civil Engineers." Mr. Homersham, a well-known and eminent authority on the subject of water engineering, tells us that the publication of the pamphlet arose in this way:—

"A water company supplying a considerable town in Yorkshire from the river flowing through it, the water being drawn at a point two miles below the town, during the last session applied to Parliament for powers to substitute for the river water, mixed upland stream, and flood water, impounded together in an elevated artificial lake.

"The application was opposed before a committee of the House of Lords, to whom the Bill was referred, by several parties, on various independent grounds, supported by

evidence to prove that, an adequate quantity, at a less charge, and of a better quality, could be obtained and supplied from the enormous natural store of subterranean water contained in the new red sandstone geological formation, which crops out at the surface of the ground thirteen miles to the east of the town.

"The results of a microscopical investigation relating to the respective characters of the stream and of the subterranean water, although carefully made for the purpose, were not brought to the notice of the committee; nevertheless, the powers sought by the Bill were rejected. The microscopical results have a scientific interest beyond the purpose they were intended to serve, illustrating as they do an important difference between the respective characters and wholesomeness of two classes of water at present not widely enough understood; for this reason I have recorded them in the following pages, accompanied by a few short introductory and explanatory notes."

It is remarkable enough to find that neither the Royal commission of 1866, nor that issued at a later date, took any trouble whatever to institute a microscopical investigation of the numerous samples of water collected for examination, although in their report we find it stated that "with living microscopic organisms chemistry is unable to deal, and other modes of examination are needed." The Commissioners failed, therefore, in their duty to the public, inasmuch as they unfortunately left us in the dark as to some of the most important characteristics of the unwholesomeness of waters submitted to their judgment. Now, essential as it is to know what are the chemical qualities of water, it is of equal importance that a concurrently well conducted microscopical examination should at all times be made before a correct judgment can be pronounced on the condition of the water, and its freedom from the worst form of pollution and danger to health.

Dr. Hassall, in 1857, in a report addressed to the President of the General Board of Health of the day, gave the results of an elaborate microscopical examination of the metropolitan waters, and showed that Thames water taken at Hampton, and, after filtration, when conducted to the metropolis through the pipes of the companies, contained a large quantity of minute organisms, vegetable and animal. No more recent microscopical examinations have been made by order of the Government, consequently many of the essential conclusions arrived at in the Report of the Royal Commissioners, founded as they were upon insufficient data, will only be regarded by those more fully informed on the subject as containing grave inaccuracies; while in many particulars the statements in it are directly opposed to the evidence given by Dr. Frankland, and to the deliberate conclusions arrived at by the late Professors Graham and Miller, and of Professor Hoffman, who were appointed as commissioners to report on the chemical quality of the London water supply.

Many of our large provincial towns, however, have, within the last few years, entirely abandoned river waters for domestic uses, and now take their supply wholly from deep subterranean sources; and it cannot be too widely made known "that uncontaminated deep spring or subterranean water, so abundantly, so readily, and so cheaply obtainable from the copious stores treasured up in capacious natural reservoirs formed by minute but numerous pores that pervade the thick strata of chalk, new red sandstone rock, upper and lower green sand, and other porous geological formations, and so abundantly and continually replenished by the rains that fall upon the large area of their exposed and absorbent surfaces, is found free from all living vegetable or animal productions, and from all putrescible organic matter.

"The normal temperature of such water is uniform, being the average of the climate at its source for the year, which in this country differs but little, being about 50° Fahr. It is at all times clear, colourless, bright, well aerated, holding per gallon seven to eight cubic inches of air in solution, and it is wholesome, pleasant, and fresh to the taste.

"On the other hand, river, stream, flood, and surface

waters impounded in lakes or ponds have a normal temperature near the freezing point in winter, and often as high as 70° Fahr. in summer.

"Careful filtration through the best filters does not separate or free such waters from decaying organic matter held in solution, from urine, from minute living animal organisms that feed and grow on their contents, and which rapidly increase and multiply therein, more especially when the water is comparatively warm, as in summer, the season when it is most abundantly drunk.

"Water so impounded frequently contains in chemical solution a few (only four or five) grains of mineral matter per gallon; this is known as soft water. Judging, then, only from chemical analysis, this class of waters, more especially when taken for examination in cold seasons of the year, might be considered to be fit for domestic use. On the other hand, these waters, more especially if taken in the warm seasons of summer and autumn, and subjected to microscopical examination, must be pronounced, owing to the quality and quantity of their organic contents, living and dead, to be, even after filtration, quite unsuited for drinking, and for many other uses.

"While river and flood waters impounded in lakes vary considerably in the hot and cold seasons of the year as regards the quantity and quality of their organic and other solid contents, it is found that uncontaminated subterranean waters, at all seasons, are quite free from organic pollution. The hot and cold seasons of the year, which so much affect surface waters, have no effect upon the water buried in the deep recesses of the earth."

(To be continued.)

## Notes on Current Topics.

### Hospital Saturday Fund.

THE contributions to this fund not having been so large on the day set apart as the committee had anticipated, a resolution was come to declaring the fund open for another fortnight. The working classes appear as a whole to have contributed but very scantily. To this paucity of pecuniary interest taken by them we are pleased to observe some praiseworthy exceptions—for instance, the *employés* at Messrs. Peek and Frean's sent £80, Messrs. Shoolbred's nearly that amount; £92 were collected from the *employé* of the London and South-Western Railway, and so on. But the greater portion of the fund appears to have been subscribed by the employers of labour, the wealthy, and by gratuitous performances at theatres, the latter item being headed by Mr. Chatterton, lessee of Drury Lane and other theatres, by £330. Altogether the amount collected up to the time of our going to press is about £3,500. As we have before pointed out, the committee have incurred very heavy expenses in printing, advertising, cabs, flags, uniforms, and other matters, much of which was both unnecessary and derogatory to the purpose. To defray these expenses, which would reduce the receipts very considerably, a meeting was held on Monday, at which it was resolved to invite the further contributions of the wealthy to this additional fund. Of course, the question naturally arises as to the propriety of calling the fund by some other name; it has lost its title to "The Saturday Fund," and it certainly cannot be termed a working man's fund.

THE jubilee of the Edinburgh Academy was celebrated on the 16th inst. by a banquet, at which the Archbishop of Canterbury presided.

### Alcoholism among the Easy Classes.

DR. LEUDET, of Rouen, mentions a series of researches made on 200 patients of his private practice in a short memoir on the above subject. One of his studies, a medical man, unfortunately a great drinker, was not contented with alcohol, but used to inhale 150 grammes of alcohol daily. He taught a servant to make him inhale it for hour hours at a time, and thus used five kilogrammes of chloroform in a year. He was attacked with gangrene of one of his toes.

Among the principal effects of chronic alcoholic poisoning among the easy classes, Dr. Leudet speaks of gout, disease of the stomach, and dyspepsia, and, according to him, affections of the liver (cirrhosis) are more frequent than among the working classes. Chronic diarrhoea, lasting for 15 or 20 years, and paralytic accidents, are mentioned, some of which may be cured by leaving off alcohol when they have not advanced too far.

Dr. Verneil, of Paris, confirms the assertions of Dr. Leudet, and notices that the administration of chloroform often shows that persons beyond suspicion have been secretly addicted to alcohol. It is always more or less dangerous to give such persons chloroform, on account of the tendency to congestion of the lungs.

### Charity Organisation.

WE find in the *St. Louis Medical Journal* a protest against the monstrous abuse of charity in that city, which it would be well if London hospital administrators would "inwardly digest." There are thousands and tens of thousands of people in our large cities, says our contemporary, who, if they can get medical attendance and medicines gratuitously when sick, and quarters in hospital if disabled by accident or disease, will never provide for a day a-head, but spend half their earnings at dram-shops. The more charity, the more left for whisky; and the more whisky, the more charity needed; until the city is given over to saloons and charity-institutions; one-half of the population engaged in making drunkards, and the other half working hard to take care of them.

Could any statistician tell us what fraction of each £1 given in London medical charity reaches a really deserving object? Perhaps if he would first write off, say 8s. for establishment charges, from which the poor man benefits little or nothing; then 40 per cent. of the remainder, say 5s., for aid given to well-to-do shopkeepers and the opulent middle-classes; then 50 per cent. of the remainder, or say 3s. 6d., for those who are paupers by their own wilful act, and deserve neither sympathy nor assistance,—possibly half-a-crown in each pound (and we are inclined to think much less) remains for the destitute sick, who would make prudent provision for their illness if they could, and are prevented from doing so either by their poverty or other reason beyond their own control.

### The Medical Council.

WE understand that Professor Humphry was last week elected to the vacancy on the Executive Committee caused by the elevation of Dr. Acland to the Presidency of the Council in July last. At the next meeting of the Execu-

tive Committee, which will probably take place in about ten days, it is expected that the visitors of examinations will be chosen from the various licensing bodies, who have in most cases sent in the names of gentlemen willing to fill the office.

### Triple Paralysis of Eyeball from Syphilis.

DR. A. FOURNIER (*Ann. de Derma. et de Syphil.*, v. 5), in 1873, observed a young girl affected with syphilitic palsy of the eyeball, which gave her a very curious aspect. She had suffered for four years from syphilis, and had not had any treatment. Disorders in her speech dated four months back, and appeared after violent nocturnal headaches, to cure which the patient took a few mercurial pills. On the right side there was seen paralysis of the third pair, manifested with its classical and usual characteristics (drooping of the upper lid, inability of looking upward, downward, or inward, considerable dilatation of the pupil). On the same side there was paralysis of the sixth pair, so that the movement of the globe outwards was absolutely abolished. On the left side there was simply paralysis of the sixth. The young woman was quite well in other respects.

The prescription was: Daily friction with four grammes of double mercurial ointment, gargle with chlorate of potash, three tablespoonfuls of syrup of the iodide of potassium, made with thirty grammes of the iodide in 500 of water, sulphur-baths; afterwards, the dose of the iodide was doubled, and that of the ointment made four-fold.

The ocular lesions were perfectly cured, but further on there was a new syphilitic manifestation—an ulcerated gummy tumour of the left leg, testifying to the intensity of the disease.

The author concludes his note with the following observation: "The interest of this case resides in the multiplicity of the paralytic disturbances presented by the patient. Three nerves were affected in her (the sixth pair on the left side, the sixth and third on the right), and these three nerves were affected by the syphilitic affection, as the evolution of the disease evidently demonstrated, and the result of the specific treatment. Now, this union of multiple paralysis is worthy of being remarked. It is observed more perfectly in syphilis than in any other disease; it has, therefore a diagnostic value.

### Determination of Sex in Utero.

THE *Chicago Medical Examiner* has an interesting paper from Drs. A. B. Strong and D. Steele, containing the results of careful examination of 100 pregnant females, with a view to test the truth of the recently proposed method of determining the sex before birth. They found that in the majority of cases the male heart was slower—that 132 per minute was the average dividing line—that above this 53 per cent. were females, and 27 per cent. males; while below it 63 per cent. were males and 20 per cent. females—that repeated observations were required for the purpose of accuracy—that the last month of gestation was the best time for observation, that the heart's action was increased in rapidity in proportion to the feebleness of the foetus, and that a diseased condition of the

placenta might be diagnosed in some cases. The report concludes as follows:—

"As regards the artificial divisions of the uterine tumour given above, we found the foetal pulsations most distinct in the left lower quarter in thirty cases, in the left upper quarter in five, and in the right upper quarter in three, the latter all cases of breech presentation. All the others were vertex, forty-one in the first position, and six in the third. If the foetal heart be heard most distinctly above the imaginary transverse line, the presentation is most likely that of a breech; if below the line, it is almost certainly a case of vertex presentation. Inspection and palpation, however, afford valuable information in the determination of the foetal position, and exclusive reliance should not be placed upon auscultation.

"In conclusion, it may be generally stated that we find an opinion as to the sex of the child, founded on the rate of the foetal pulse, to be of little more value than a guess, while the presentation, generally, and the exact position, possibly, may be accurately determined."

### The Action of Veratrum Viride upon the Circulation.

THE *Philadelphia Medical Times* contains a series of important experiments on this subject by Drs. Wood and Berens, from which they deduce the following conclusions:—

The action of this alkaloid upon the circulation is altogether subordinate to its influence upon the respiration.

In minute doses it stimulates the cardiac inhibitory nerves or nerve-centres, but when given in sufficiently large doses it finally paralyses the peripheral inhibitory cardiac nerves.

It exerts some action upon the heart-muscle or the contained ganglia; this action is probably a sedative one, but it is very feeble, and is only distinctly perceptible when the drug is precipitated at once upon the heart, or when the dose given is much above that required to arrest respiration. To kill the heart-muscle very large amounts are required.

Upon the vaso-motor system veratroidia acts as a depressant, but its influence is feeble, much less intense than its action upon the pneumogastriacs. When artificial respiration is maintained, it can be given in such doses as to paralyse the vaso-motor centres.

### Artificial Production of Actinism.

DR. H. VOGEL has lately made a singular and interesting discovery in actino-chemistry, namely, that the non-actinic rays may, under certain circumstances, be made actinic. He has found, says the *Photographic News*, that bodies which absorb the yellow ray of the spectrum make bromide of silver sensitive to the yellow rays. In like manner, bodies which absorb the red ray of the spectrum make bromide of silver sensitive to the red rays. For example, the addition of *corallin*—which absorbs the yellow ray—to a bromide of silver film renders it as sensitive to the yellow ray as to the blue ray. The discovery is one which will doubtless prove to have important practical bearings.

### Sal-Ammoniac as a Febrifuge and Sedative.

*L'Union Médicale* refers to a series of cases communicated to the Société de Thérapeutique by M. Martineau, which tend to show the value of sal-ammoniac in acute rheumatism, the results of which are noted in the *Philadelphia Reporter*. Some cases are said to have been cured

and in others the pulse and temperature decreased after the medicine. Dr. Lupeyrère, in *La France Médicale*, gives some further notes on the subject. He states that Delieux de Savignac found daily doses of half a gramme too feeble, and gave from four to ten grammes. He carried the quantity per diem to fifteen grammes in divided doses, for the relief of nervous headache. Dr. Burrillen, of Toulon, in the *Bulletin de Thérapeutique*, has related many cases cured by three doses of one gramme each, given at intervals of half an hour. Some English physicians have used the drug successfully in nervous affections. Delieux de Savignac has used it both externally and internally in gout, as well as acute rheumatism, and says it diminishes both pain and fever. It may be dissolved in any of the waters of the Pharmacopœia. Its trial is advised in doses of five, ten, and fifteen grains.

### Importance of Urinary Casts.

DR. CHARCOT (*Le Progrès Médical*, Sept. 19th) says that, as a general remark, it may be said that the clinical importance of urinary casts has been much exaggerated. They are not, as has been said, faithful messengers, announcing to the clinical observer the anatomical state of the kidney, or mirrors reflecting the different renal affections. Formed in the latter end of the uriniferous tubes, they can only give information as to the state of these parts; and cylinders formed in the twisted parts of the tubes cannot pass into the urine.

MR. JESSEP, of Sheffield, has offered to the Committee of the Hospital for Women a site on which he proposes to build a new hospital for the town, at a cost of £12,000.

DRS. LATHAM and BRADBURY are candidates for the Downing Professorship of Medicine, vacant by the decease of Dr. Webster.

DR. GRAILY HEWITT has been elected an Honorary Corresponding Member of the Philadelphia Obstetrical Society.

A BARONETCY is talked of for Dr. Arthur Farre, the physician-accoucheur present at the confinement of the Duchess of Edinburgh, and who has officiated on several occasions of the kind in the charmed circle of royalty. We should welcome such a recognition of his services; but there are others also to whom such honours ought to be extended. We have more than once spoken of this.

ACCORDING to the Registrar-General's return, there were 2,383 births and 1,344 deaths registered in the metropolis last week. The births exceeded by 51, and the deaths were 97 below the average numbers. The death-rate, which had in the three previous weeks been equal to 17, 18, and 19 per 1,000 of population, rose last week to 21.

THE proposed testimonial to Dr. Sedgwick Saunders, Medical Officer of Health to the City of London, for his unwearied exertions to found a free library for the citizens, will soon assume a tangible form. The committee who have undertaken the collection of contributions met

at the Mansion House on Tuesday week for the transaction of business, but a journeyed for a month, to await the result of an important movement for the same object commenced in the ward which Dr. Saunders represented for many years in the Common Council.

## Literature.

### WEST RIDING ASYLUM MEDICAL REPORTS. (a)

THERE can be no question that the West Riding Asylum is the centre of psychological medicine in this country, and has done more in recent years for neuro-physiology and pathology than perhaps any other institution of the kind in Europe. It has become a celebrated school for the training of those who are desirous of entering that special department of practice which is concerned with the treatment of diseases of the mind. It has been constituted a rallying point for the whole medical profession in the district in which it is placed, and it has contributed much valuable information to our knowledge of cerebral action, normal and abnormal. It has done all this, too, without failing in any jot or tittle of that law of humanity and order which now happily regulates the administration of our lunatic hospitals. Pre-eminent in its scientific work which it has accomplished, it has in no degree fallen behind in its general condition. We gather from the Reports of the Commissioners in Lunacy that as regards the domestic comforts of the inmates, the employments and amusements provided for them, the discipline of its staff, the cleanliness and comeliness of its wards, and the whole economy and efficiency of its management, the West Riding Asylum is fully on a level with the best asylums in this country; and we can therefore congratulate the medical officers of that establishment on the demonstration which they have afforded that a diligent pursuit of scientific medicine is not incompatible with a due attention to moral and financial government.

The volume of Medical Reports which now lies before us is the fourth of an annual series, which we are glad to learn is now securely established. Undismayed by the difficulties and discouragements which beset the commencement of this undertaking, Dr. Crichton Browne and his colleagues have persevered in their work, and have raised the yearly record of their professional researches into a position of well-merited distinction and prosperity. They have provided the only periodical of which this country can boast devoted to the physiology and pathology of the nervous system, and they have concentrated in that periodical an amount of ability and industry which gives to its pages an incalculable value. Year by year these Medical Reports have improved in quality and risen in estimation, and it may be safely asserted that the issue for the present year is a most important and interesting addition to medical literature. Of the twelve papers which it contains, none can be regarded in the light of padding. All are replete with original observations and with practical suggestions. The first of them, from the pen of Dr. Carpenter, is a critical examination of the physiological import of Dr. Ferrier's experimental investigations into the functions of the brain. It is really an extended version of the address which Dr. Carpenter delivered at the medical *conversazioni* at the West Riding Asylum last winter, and must be read with careful attention by all those who desire to keep abreast of modern physiology. In the main, Dr. Carpenter accepts Dr.

Ferrier's conclusions, and does not attach much weight to the cavilling objections which have been made to them. Some of Dr. Ferrier's positions he most ably and ingeniously illustrates. Upon one or two points, however, we believe we detect a divergence between the views of Dr. Carpenter and those of Dr. Ferrier.

The second paper is on "A Case of Recovery from Double Optic Neuritis," and is illustrated by two admirable chromolithographs by Burgess. The case shows in a striking manner the value of the ophthalmoscope to the physician and the remarkable power of accurate prediction which Dr. Hughlings Jackson has attained in nervous diseases. It demonstrates that sight may be good when there is extreme optic neuritis, and that the neuritis may disappear, the disc resuming what is practically a normal appearance. Incidentally, Dr. Hughlings Jackson takes occasion to point out that optic neuritis from syphilitic disease of the brain is not syphilitic optic neuritis.

The third paper—which is by Professor Ferrier, and is entitled, "Pathological Illustrations of the Brain Function"—has a peculiar interest, as it is a practical application of its author's recent discoveries to the explanation of the facts of disease. Five fatal cases of organic disease of the brain are reviewed in it, and their symptoms are shown to have been in perfect harmony with the results of experimental inquiry. While commenting upon these cases, Professor Ferrier makes a most telling rejoinder to Dupuy, Curvillat, and other critics, and corrects certain misapprehensions which have been formed as to his views.

Following Dr. Ferrier's essay is one by Dr. John Merson upon "The Urinology of General Paralysis." This is a most clear and careful production, and at once marks out Dr. Merson as a man of great capacity and high attainment. The principal conclusions arrived at are that in general paralysis the quantities of urea and uric acid in the urine are considerably increased, while the quantities of chlorides and phosphoric acid are notably diminished, and that under the influence of calabar bean and alcohol during the progress of that disease there is a large diminution of all the solid constituents, and especially of the urea.

The paper by Dr. Milner Fothergill on "Cerebral Anæmia," which follows Dr. Merson's, although the longest, is perhaps the least meritorious in the volume. There is an air of speculation about it that suggests the library rather than the bedside, and betrays a vigorous imagination as yet inadequately disciplined by the tedious routine of facts. It is, however, what would be called an eminently readable article, and is so discursive that it ranges from Middlesmarch to Virchow and from Darwin to Mrs. Dombey. It includes excellent observations upon local cerebral anæmia, and some shrewd hints as to treatment.

In the sixth paper Dr. W. T. Benham discusses the therapeutic value of the application of cold to the head, and gives good grounds for his belief that that value has been exaggerated. His experiments have been ingeniously devised and patiently executed. Those with Ludwig's Stromuhr are especially instructive.

Dr. Lauder Brunton's essay upon "Inhibition Peripheral and Central" is an inquiry into the operation of the will from the physiological side, and will not be less attractive to metaphysicians than to practical men. It is certain to be closely studied, and to be frequently referred to as the ablest exposition which has been attempted of an obscure topic.

Mr. Major's annual essay upon "Cerebral Histology" is looked forward to with interest by all those who are engaged in microscopic researches. Mr. Major is recognised as an intrepid

(a) "West Riding Asylum Medical Reports." Edited by J. Crichton Browne, M.D. Vol. IV., 1874. Smith, Elder, and Co., London.

original investigator in those remote polar regions explored by few, in which the conscious needle turns, but, as we fear, is never to be nailed. His work is eminently accurate and honest, and his inferences are fair and cautious. This year he describes his observations in senile atrophy, and enumerates changes in the cells, fibres, vessels, and neuroglia, pointing out that, although none of these changes is individually destructive of senile atrophy, yet the grouping of them is essentially characteristic of that condition. He has discovered that the cells in the focal brain are uniform in size, circular in form, and entirely destitute of branches.

After Mr. Major's paper comes one by Mr. Lawson on "The Hourly Distribution of Mortality in Relation to Recurrent Changes in the Activity of the Vital Functions." This essay has a statistical basis, and possesses both literary and scientific merit. It demonstrates the existence of a law regulating the hours of maximum and minimum mortality. Next comes a careful clinical study of acute dementia from the powerful pen of the editor, Dr. Crichton Browne, accompanied by a characteristic heliotype portrait; and following that again there is a paper upon ophthalmoscopic work performed by Mr. Charles Aldridge. The volume is brought to a close by some novel observations on the actions of nicotine, by Dr. W. T. Benham, who has discovered that that agent has the power of producing contraction of the pupil, whether applied topically or taken internally.

Altogether, this collection of essays, which we have merely enumerated, is a most noteworthy one. That it should proceed from a provincial medical institution is remarkable, and truly honourable to those who guide and govern that institution.

#### ARCADIAN WALKS AND DRIVES IN THE NORTH-WEST SUBURBS OF LONDON. (a)

THE author has for many years recommended muscular exertion to his patients, and knowing how irksome exercise for exercise sake becomes, has prepared a pocket guide to the pleasantest walks and drives within reasonable distance of the North and West Londoner, telling his readers how to walk, which way to go, and what to look for, in a pleasant chatty style.

#### ILLUSTRATION OF THE LITERATURE OF QUACKERY.

THE August number of the *Chicago Pharmacist* contains the following editorial comments on the address on this subject delivered by Henry Gibbons, M.D., before the California State Medical Society, and which we lately republished in this country. The comments of the *Pharmacist* are thoroughly American, but none the less interesting and instructive; moreover, they show the real value of Dr. Gibbons' address, and make us feel the more gratified at having made it known in this country:—

We call the attention of our readers to the address, so that they may view the topic through the spectacles of a medical editor, teacher, and practitioner. As far as Dr. Gibbons has "illustrated" the subject, just so far it is good and truthful; but we sincerely regret that so fearless and able a writer as the author of this essay should have omitted mentioning the part the medical profession and its press play in the drama of Quackery.

We claim that the medical profession of this country is to a great extent responsible for the existing evil, and to substantiate our charge we will enumerate—first, the prescribing of nostrums by the medical profession, the composition of

which they have not the remotest knowledge of; secondly, the giving of certificates of merit to the manufacturers of nostrums; thirdly, that the medical press of this country, with but few laudable exceptions, assist the use and sale of nostrums by inserting into the pages of the reading matter (styling it usually selected matter), month after month, cases of diseases which have been successfully treated by the use of this or that nostrum. These cases are written up by some "medical hireling" in the employ of these nostrum compounders, and the medical journals receive a money consideration for their insertion.

To prove the first charge we have made, it is only necessary to consult the prescription file of any dispensing pharmacy, where can be found prescriptions from regular graduated physicians for such nostrums as McMunn's Elixir of Opium, Bromo-Chloralum, Elixir Iodo-Bromide of Calcium Compound, Cincho-Quinine, &c.

Secondly, on examining the wrappers attached to these nostrums, the names of physicians will be found endorsing the merits and the composition, the latter of which they are certainly ignorant of.

Thirdly, the medical press of this country has become, with few honourable exceptions, the aider and abettor of this species of fraud, by inserting among the reading matter paid "puffs," which seem to the uninitiated medical practitioner as *bona fide* reported cases of disease successfully combated by means of this or that nostrum, when in reality it is written up by the man "Friday" of the nostrum houses, and by them sent to the different medical journals from month to month, paying a consideration for each insertion.

That this aiding of Quackery is not confined to the "little fish" of the profession, we will prove by referring to the present President of the American Medical Association, Wm. Bowling, M.D., of Nashville, Tenn., who is editor and proprietor of the *Nashville Journal of Medicine and Surgery*, late President of the Meeting of American Medical Editors, and Emeritus Professor of the Theory and Practice of Medicine in the Medical Department of the University of Nashville.

This gentleman, whom we have alluded to as holding these different prominent positions in the medical profession, inserted in the June number of his journal a "puff" for the well-known nostrum, Cincho-Quinine.

For this insertion he received, no doubt, the usual compensation from the manufacturers of this nostrum. Now, we ask, what prompts men in such positions to sell themselves for such base purposes? It is certainly unprofessional, and cannot be styled honourable for one who professes to be a leader of the science of medicine, and be guilty of such an offence against its progress.

Dr. Bowling and other editorial colleagues who are guilty of this transgression certainly cannot claim ignorance on this subject. How does this agree with Dr. Bowling's questions on professional ethics, published in his journal for July? Did the Doctor, in his annual address as President of the American Medical Editors' Association, touch upon the subject of advertising nostrums by the medical press?—the address is said to have been both "suggestive and timely"—or did it only refer to the more important medical topic, "Katy did, and Katy didn't?" Come, Doctor, step to the front; tell your readers you have been "naughty" for "filthy lucre's" sake, and you have thought the matter all over, and promise for the future to mend your evil ways. It shall not be said that Dr. Bowling "*knew the right, yet still the wrong pursued.*"

#### Mendacity of Quacks.

If Satan has ever succeeded in compressing a greater amount of concentrated mendacity into one set of human bodies above every other description, it is in the advertising quacks. The coolness and deliberation with which they announce the most glaring falsehoods are really appalling. A recent arrival in San Francisco, whose name might indicate that he had his origin in the Pontine marshes of Europe, announces himself as the "Late Examining Physician of the Massachusetts Infirmary, Boston." This fellow has the impudence to publish that his charge to physicians in their own cases is \$5 00! Another genius in Philadelphia, of the bogus diploma breed, who claims to have founded a new system of practice, and who calls himself a "Professor," advertises two elixirs of his own make, one of which is for "all male diseases" and the other for "all female diseases." In the list of preparations which this wretch advertises for sale as the result of his own labours and discoveries is *Ozme*!—*Pacific Medical and Surgical Journal*.

## Correspondence.

### BATHING QUARTERS ON THE STRAITS OF DOVER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I found in your impression of September 30 some very interesting remarks by my friend and former colleague Dr. Drysdale, who signs himself "Hygiene," upon my adopted sea-side home. As he appeals to me for some information as regards the hygienic state of Boulogne, and as I am in a position to forward him the same, I can only add before I begin my remarks that I am infinitely obliged to him for eliciting from me some facts and figures which will not only go far to establish our town as the "Queen of French watering-places" in the eyes of the profession, but also in those of the numerous visitors who annually visit our *ville de plaisance*.

To begin with, I beg to inform "Hygiene" that diarrhoea and adynamic diseases do not exist in the lower part of the town more than they ought to do, any more than they ought not to do in the haute ville.

Boulogne is decidedly a very healthy place to live in—I say to live in because I believe until one gets acclimatised, the atmosphere, with its frequent changes of temperature, is very trying, especially to persons suffering from diseases of the chest.

As regards a bathing resort, I will only state the number of baths taken in connection with our charming Etablissement des Bains from June 15 till September 30: The warm and douche baths numbered 7,000; swimming baths, 12,500; in the sea, 69,000—total, 98,500; and there are two other bathing établissements on the sands. These figures speak for themselves.

Our death-rate is a very low one, and considering the number of factories surrounding Boulogne, accidents are very rare indeed. Some of the factories employ 800 to 1,000 hands, and yet during the past twelve months there has scarcely been any serious accident brought to the Hôpital St. Louis.

And now about the vexed question of the drainage: I admit that there is not a pleasant odour at low-tide from the bed of the Liane along the quays; and also that there exist at the present time several outlets from all parts of the town at various parts of the harbour and river. Notwithstanding this, I do not believe we have more epidemics (typhoid fever, for instance) near the river than in the upper town.

On Thursday last I had an interview with M. de Poilly, the chief engineer of Boulogne, and he was kind enough to inform me of some prospective drainage arrangements, and show me the plans. That these will be carried out there is no doubt, as the money is voted, and all ready to begin operations. The authorities have not yet set to work, because they want to combine with the main drainage a thorough good system of water supply, and are anxious to make one loan only—viz., of 2,000,000 francs. Should the water supply question, however, fall through, the drainage one is certain.

And, now, what is the system? you naturally ask. To carry a large drain from below the abattoirs on the Liane all along the quays, to pass in front of the Pavilion Hotel, and be carried out to sea beyond the old fort on the way to Calais, or to pass alongside the East Jetty, and so carried out to sea. I much prefer the former plan, because of the bathing.

I trust, Sir, I have now satisfied "Hygiene" with my answers to his questions.

The "feature in Boulogne peculiarly agreeable to the medical mind," Jenner's statue, was erected on the quay during the mayoralty of Dr. Lirois. Was there *never* one in London? I thought so once, in Trafalgar Square, where there are Lions of another sort.

I am, Sir,

Yours faithfully,

SIDNEY CHATER,

### "THE STUDY OF LIFE:" A MEDICAL REVIEW.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having seen in a contemporary this day a notice of my pamphlet on "The Study of Life" (which, by the way, as a reprint of a single lecture delivered before a popular audience, I did not fancy would have excited the outburst of splenetic zeal displayed in four pages of a review in a scientific journal), I was struck by the following passage: "Even in purely medical matters we find the most extraordinary statements, as that the most fatal form of jaundice is produced by mental depression, and that the posterior staphyloma which causes myopia is an affection of the optic nerve and retina," which he looks on as "*startling*." I would simply refer the writer, in the first instance, to any modern authority, and he will find such "extraordinary" statements in abundance. I merely select the chapter on liver diseases, in Watson, though, as of course is well known, Budd described the post-mortem appearances, and the pathological changes which mental shock produces in this organ, in cases of death, and the immediate cause of rapid delirium, convulsions, and coma in such instances. But such a statement, though it "*startled*" the reviewer, would not have surprised even a student of Cullen, who wrote of the "*Pathemata Mentis*." But he perhaps objects to my ideas of its *fatality*; he certainly may have suffered from some myopic abnormality (and this, after all, is rather a charitable view of his ignorance) when he studied the diseases of the liver, or it may be he himself suffered from some temporary derangement of this organ, so that when writing he took a slightly jaundiced view of matters. In addition to any mild cholagogues which may suggest themselves to his mind, I venture to remind him of these quotations from Sir Thomas Watson: "Fits of anger, of fear, and of alarm, have been presently followed by jaundice." He instances the case of an unmarried female, who, on its being accidentally disclosed that she had borne children, became suddenly yellow; and also that of a medical student, who got intense jaundice in connexion with an examination. Adding this "*extraordinary statement*," there are scores of instances on record to the same effect, and this is observable of such cases, "that they are often fatal, with head symptoms;" and, more extraordinary still, he says "the prognosis of jaundice is generally favourable, *except when it depends upon structural disease of the liver, or great mental or bodily shock*." In both these cases the prognosis is bad or doubtful. "Over this secretion," says Dr. Aitken, "the mental state seems to exercise a very remarkable influence, so much so, that mental emotion, favouring congestion of the organ, favours the stoppage of the secretion;" and he gives as causes of "acute yellow atrophy of the liver," "mental distress" and "nervous depression," of which Niemeyer writes, "It is doubtful if it ever ends in recovery." Strange that the reviewer never appears, then, to have heard of any of these "*extraordinary statements*." The other "*startling statement*" which I made to a popular audience, whose keen appreciation of terms was not supposed to have reached the distorted proportions, which it evidently has assumed in the writer's mind, though it is clear from his review that he has some doubts as regards his own mental relationships, was simply, that "the 'abnormality' of the optic nerve existing in a short-sighted person is recognisable with the ophthalmoscope, and that it is an hereditary affection appearing (as posterior staphyloma) in several members of the same family." I simply refer him to the latest edition of Wells for a verification of this "*startling*" sentence. Soelberg Wells says: "Myopia is frequently congenital, and often hereditary, and its existence may also be sometimes traced back through several generations, increasing perhaps somewhat in degree in each successive generation. It may also occur in several members of the same family. The most frequent cause of myopia is an abnormal increase in the length of the eyeball in its antero-posterior axis. This extension occurs chiefly at the posterior portion of the globe, and may give rise to a more or less considerable ovoid bulging (posterior staphyloma), which is accompanied by thinning and atrophy of the choroid and sclerotic. But even if this should not be present, the ophthalmoscope often reveals a hyperæmic and congested condition of the optic nerve and retina." . . . "The optic disc (says Bader), like the adjoining distended tunics, is pushed backwards and displaced towards the inner wall of the orbit. Its position is altered. In the healthy eye the tunics are thickest round the optic

nerve ('round the optic disc'). The attachments of the nerve to the tunics are particularly strong. In the myopic eye the tunics, especially at the outer margin of the optic disc, and, in high degrees of myopia, all round the nerve, are abnormally thin." "The optic disc, as a rule, appears smaller than that of the emmetropic eye. The curvature of its surface on the side adjoining the 'crescent' is flat, or may be cupped. It is unusually convex on the opposite side. The shape of the disc is frequently oval, the long axis of the oval being vertical. The optic disc may in reality be round but appear oval." "The optic disc rarely has the natural colour throughout. Often it is too red (a hyperæmia which generally accompanies rapidly progressing myopia), or it has a greyish-pink colour." "The vessels of the retina, where they pass through the optic disc, are rarely quite like those of the emmetropic eye. They are too numerous in rapidly-increasing myopia." I could myself furnish the "startled" critic with notes of hundreds of cases of congenital myopia, attended with "abnormal states of the optic disc and retina." I added that "it would be curious to dwell on the influence which, in the life-time of an individual, lesions in the nervous apparatus of the senses might entail." I did not fancy that before long I would have afforded me so apt an illustration and source for reflection as the author of this review, whose amusing waste of time and paper on a short published discourse on a subject causing a good deal of interest at the present time can only, in my mind, arouse a feeling of pity for the doubtless enforced idleness that prompted so lengthy a dissertation. Other passages there are, not connected with "medical matters," which I might notice, but "*ex uno disce omnes*."

I remain, Sir,

Yours faithfully,

H. MACNAUGHTON JONES.

4 Camden Place, Cork, Oct. 5th, 1874.

## Obituary.

MR. JOSEPH SWAN, F.R.S.

THE death is announced of the Senior Fellow of the Royal College of Surgeons of England, Mr. Joseph Swan, F.R.S., who died at Filey, aged eighty-three. Mr. Swan became a member of the College in 1813, and for some years held the post of surgeon to the Lincoln Hospital. He was the successful competitor for the College Triennial Prize on the first two occasions of its presentation—namely, in 1822 and 1825. The subject of the first essay was "A Minute Dissection of the Nerves of the Medulla Spinalis from their Origin to their Terminations, and to their Conjunctions with the Cerebral and Visceral Nerves; authenticated by Preparations of the Dissected Parts;" and of the second—"A Minute Dissection of the Cerebral Nerves from their Origin to their Termination, and to their Conjunction with the Nerves of the Medulla Spinalis, and Viscera; authenticated by Preparations of the Dissected Parts." Subsequently appeared his well-known "Demonstrations of the Nerves of the Human Body, in 25 plates," published in 1830 in folio, and in 1834 in quarto; and his "Illustrations of the Comparative Anatomy of the Nervous System," 1835. In 1819 he was awarded the Jacksonian Prize for an essay on "Deafness and the Diseases and Injuries of the Organ of Hearing," and the same prize in 1819 for an essay on "The Treatment of Morbid Local Affections of the Nerves." His "Treatise on Diseases and Injuries of the Nerves" appeared in 1834; in 1853 a series of plates of the brain; and in 1864 "Delineations of the Brain in relation to Voluntary Motion," a series of lithographs drawn from his own dissections.

## A Novelty in Post-mortem Examinations.

At a meeting of the New York Pathological Society (*Medical Record*), Dr. Janeway proposed a new method of examining the abdominal organs without opening the cavity. This was by the introduction of the hand per rectum, and bringing away any parts within reach. In one reported case the liver and kidneys had been satisfactorily inspected by this means, without violating the injunction of the friends not to open the body.

## New Inventions.

### THE "PEN" VACCINATOR.

UNDER this name Messrs. Maw, Son, and Thompson manufacture an ingenious little instrument, which has been invented by Dr. R. Harvey Hilliard. Most of the little weapons specially made for vaccination rather overdo their work, and very few, if any of them, contain sufficient charges of lymph for a school or a good-sized vaccinating station. It is also well known that the common bleeding lancet, especially if used to make a little pocket or valve for the lymph, is very apt, with a lively and plunging child, to draw blood, which is objectionable for many reasons. The instrument shown in the figure consists of a sort of drawing-pen, like those sold in mathematical cases, made of a hard, clean, incorrodible metal, between the blades of which there is room for lymph enough to vaccinate at least a dozen children. When not in use it shuts up into its case, which, being close-fitting, constitutes a moist chamber. The other end is a reservoir for capillary tubes—either empty or charged with lymph—all ready for use. To use the pen for vaccinating, it is reversed, and being held in the hand like a pen or pencil, is used to make a scratch, which does not draw blood, but lodges the lymph at the same time. For greater certainty, a second scratch may be made as right angles, or nearly so, to the first, like a Roman X. It is also a capital instrument for arm to arm vaccination, as it charges itself by the "capillary" attraction between the blades of the pen, or it may be used simply to puncture the vesicles and charge Dr. Husband's tubes. It looks nice, is very portable and efficient, and does not frighten either baby or his mamma.

### Sponge retained in Stump after Operation.

*Le Mouvement Médical* mentions the case of a man who entered a hospital in Paris with a large granulating ulcer on the stump of his leg, consequent on amputation four months previously, in the reign of the Commune. On examination, a sponge was found imbedded in the granulations. It had been applied as a hæmostatic in the amputation and carelessly left in.

### Saccharated Calomel contains Corrosive Sublimates.

DR. POLK, of Philadelphia, in the *Medical Times*, calls attention to the fact that corrosive sublimate is developed when calomel is rubbed up with sugar. He administered ten grains a month after its preparation, with such poisonous effects as led him to test the compound, with the result as stated. He quotes from Valpius, who says: "When calomel is mixed in powder with white sugar, or calcined magnesia, or bi-carbonate of soda, corrosive sublimate is formed in twenty-four hours. Rather large quantities are formed in powders composed of calomel, white sugar, and bi-carbonate of soda." We believe it is the general opinion among practitioners that the increased activity of the saccharated calomel, which, by the way, is an old remedy, depends on the increase of surface caused by its diffusion. But the development of the chloride puts a serious face on the matter.

## THE RELATION OF THE IRISH LOCAL GOVERNMENT BOARD TO SANITARY SALARIES.

THE following letter has been received by the Irish Medical Association in response to their request that a deputation might wait on the Local Government Board :

Local Government Board, Dublin,  
13th October, 1874.

SIR,—The Local Government Board for Ireland acknowledge the receipt of your letter of the 10th instant, forwarding copy of a resolution passed at the last meeting of the Council of the Irish Medical Association, appointing a deputation to wait upon the Board for the purpose of representing to them the unsatisfactory manner in which it is proposed to remunerate the medical officers engaged in carrying out the provisions of the Sanitary Act ; and in reference thereto I am to inform you that the subject of the future salaries of the medical gentlemen who may be employed under the provisions of the Public Health (Ireland) Act is receiving the consideration of the Local Government Board, who are preparing to enter into correspondence with the Lords Commissioners of Her Majesty's Treasury on the subject.

The nature of that correspondence will be gathered from the circular, of which a copy is enclosed.

It will be borne in mind that by the Act of Parliament it was provided that the local sanitary authorities should in the first instance determine the salaries, but that the power of finally adjusting them resides in the Local Government Board, subject to approval by the Lords Commissioners of the Treasury.

The Local Government Board are prepared to perform their part of this duty with a full sense of their responsibility in the matter, and under the impression that, inasmuch as the Act of Parliament has imposed upon dispensary medical officers additional statutory duties, it is the business of the Local Government Board to see that proper remuneration is provided for these additional duties.

The Local Government Board are not aware, under these circumstances, what advantage could be derived from a personal interview with a deputation from the Irish Medical Association, but they will readily give their most attentive consideration to any suggestion which may be furnished to them by that body in a written form of communication.

By Order of the Board,

B. BANKS, Secretary.

To E. J. Quinan, Esq., M.D., Hon. Sec.  
Irish Medical Association.

## EXPOSING THE QUACKS.

THE San Francisco *News Letter* adopts a very short method with some of the unlicensed practitioners in that city, by publishing plainly a list of those *soi-disant* medical men who are trading either without any diploma or on a sham degree.

We are perfectly inundated, says the *News Letter*, with letters of inquiry and approval respecting the articles that have appeared in the *News Letter* in regard to our physicians. Those articles have brought to our knowledge an amount of charlatanism of which we had no previous conception. It is undoubtedly a most dangerous thing to send for a doctor in San Francisco unless you know who you are sending for. In view of the facts that have come to our knowledge, we feel assured that we shall be equally serving the profession and our citizens generally when we publicly ask certain men : "Have you a diploma ?" If

they have, we will give them an advertisement gratis. If they cannot answer the query, the conclusion is obvious, and the duty of their patients plain. We append a list of practising medical men, to whom we now put that question. We shall add to it from time to time.

Then follows a roll of eighteen practitioners, with the query, "Gentlemen, have you a diploma ?" in large letters, preceding the list. The *News Letter* goes on to say :—

Dr. C. T. Deane, Professor of Diseases of Women and Children, and Clinical Obstetrics, in the Medical Department of the University of California, has called upon us, and claimed to have a diploma from Giessen, in Germany. He did not claim to have any other. He never lived in Germany for any time, and *does not speak the language*. They sell diplomas in Giessen for coin. Those who think that diploma guarantees that Mr. Deane possesses skill, or even a medical education, may continue to think so.

We should be glad to know which of our journalistic leviathans would have the pluck to follow the example of their Pacific contemporary. Not one ! The temptations of well-paid advertisements and the dread of a summons and plaint are too much for their courage.

## "FIRST PLACE BY COMPETITION."

WE have seen a copy of the *Clonmel Chronicle*, in which a Dr. Sparrow—of the Queen's University and Edinburgh Double Diploma, who describes himself as "late Surgeon (first place by competition) Royal Navy"—publicly advertises that he will visit anyone for five shillings.

We can understand that a practitioner who thinks it right to take this road to practice is not likely to have appreciated, or been appreciated in, the society of gentlemen of the Royal Navy ; and we hope we shall not be wrong in predicting for him the first (and last) place in the questionable competitions with the grocers, haberdashers, and tinkers who contest with him the publicity of the *Clonmel Chronicle*.

THE State Board of Health of Massachusetts has issued circulars for the purpose of investigating certain facts in regard to the "supply of meats to large cities," and submits the following questions to a large number of British practitioners :—

1. Do you think that terror in animals produces any change in secretions or in flesh, whereby their milk or meat is rendered injurious as food ?
2. Do you know any facts bearing on this question ?
3. What do you think is the effect upon their flesh for the market, of depriving animals of food and drink for twenty-four hours, provided this be a day or two before they are killed ? or, secondly, immediately before they are killed ?
4. What diseases, and what stages of disease in animals do you think render their flesh injurious as food ?
5. Is meat rendered injurious as food by hanging in an atmosphere tainted by decomposing animal matter ?
6. What do you consider the best method of slaughtering animals for the market ?

Any facts, pamphlets, papers, or references to journals and books upon these subjects would be very gratefully received by Chas. F. Folsom, M.D., the Secretary of the Board

## THE DUBLIN INTRODUCTORIES.

THE opening of the School of the Royal College of Surgeons took place on Monday last by a lecture from Dr. Emerson Reynolds, Professor of Chemistry in the College. Dr. O'Leary, M.P., inaugurates the session to-day (Wednesday) at St. Vincent's Hospital by a discourse on the Public Health System of Ireland. Dr. Kelly will deliver the introductory at the Ledwich School, on Monday next, at 12 o'clock, and Dr. Thomson at the Richmond, on Nov. 5th. The lecture at the Meath Hospital will be given by Dr. Robt. Perse White; at the Mater Misericordias Hospital by Dr. John Hughes; and at the Catholic University, by Dr. Hayden. In the remaining schools and hospitals an introductory will be dispensed with.

## IRISH MILITIA MEDICAL OFFICERS.

It is confidently rumoured, says *Saunders's News Letter* (Dublin), that the services of the civilian medical officers attached to the different regiments of militia will shortly be dispensed with, they receiving a money allowance on the occasion according to their length of service with those corps, and that medical aid to the militia will in future be afforded by officers of the Army Medical Department doing duty with the troops quartered at or near the militia head-quarter station.

## THE SCARLATINA IN IRELAND.

THE Registrar General's returns of last week report an apparent decrease of mortality from scarlatina in Dublin, the deaths being 20 as compared with 27 last week. In Belfast there were 31 deaths from the same cause, and, of the total number of deaths in that town, 87, nearly one-half—40—resulted from zymotic. In Monaghan nine additional patients were removed last week for treatment in the Fever Hospital. In an adjoining county scarlatina has been very prevalent for some time. From Longford it is reported that the disease still continues to ravage the town and its neighbourhood, few families escaping the infection. Several mothers have been stricken with it after their children had recovered. Active measures are being taken by the sanitary authorities for the purpose of cleansing the town.

DEPUTY SURGEON-GENERAL CHARLES MURRAY DUFF, of the Madras Medical Department, died in Burmah on the 31st ult. He had served upwards of thirty-two years, and obtained the rank he held at the date of his decease in February of last year.

DR. THOMAS WILDRIDGE SHIELL, the resident medical superintendent of the Ennisorthy Lunatic Asylum, was found dead in his bed a few minutes after seven o'clock on Monday morning week. Dr. Shiell served for a considerable time in the army, and was for some years resident medical officer of the Maryborough District Lunatic Asylum.

THE next meeting of the Pharmaceutical Society of Great Britain will be held on Wednesday evening, Nov. 4, 1874, at eight o'clock. On this occasion a discussion on the "Chemical Nomenclature proper to an International Pharmacopœia" will be introduced by Mr. Thos. Greenish. The following paper will also be read: "Suggestive Notes on the Pharmacy of Amorphous Phosphorus"—Mr. Arthur W. Postans.

**Army Appointments.**—The *Army and Navy Gazette* states that Deputy-Inspector-General of Hospitals and Fleets William Loney, who has been stationed at Hong Kong since September 18th, 1872, has been appointed to Haslar Hospital, vice Nelson, whose period of service is about to expire. Dr. Loney, in addition to the lengthened term of office as above mentioned in an unhealthy colony, had previously served in the Red Sea, and has fairly earned the desirable appointment to which he has now been nominated. Deputy-Inspector of Hospitals and Fleets David Lloyd Morgan, C.B., M.D., has been ordered to hold himself in readiness to proceed to Hong Kong to relieve Dr. Loney.

## NOTICES TO CORRESPONDENTS.

DR. J. M. C.—We announced the fact some months since. Space is too valuable to repeat.

**CURIOSITIES IN LONDON POPULATION.**—One of the religious societies of the metropolis, describing London, says that the police boundaries cover 576 square miles and a population of 4,000,000 of inhabitants; that there are here gathered more Jews than there are in Palestine, more Scotch than there are in Edinburgh, more Irish than there are in Dublin, more Roman Catholics than there are in Rome, and that there is a great variety in the languages spoken. There is a birth in London every five minutes, and a death every eight minutes.

DR. WILLIAMS had better write to the publishers.

**ROYAL COLLEGE OF SURGEONS OF EDINBURGH.**—A list of the office-bearers recently elected will be found on reference to our advertising columns.

MR. D. M.—The gentleman named in your note has left this country for a short time.

DR. H. G.—The work has not yet been received for review.

OUR INDIAN CORRESPONDENT'S LETTERS shall appear in our next.

**SCARCENESS NUMBERS.**—The Publisher will be glad to purchase clean copies of January 14th and June 3rd, MEDICAL PRESS AND CIRCULAR of this year, or to supply any others in lieu thereof, on application to the London office, King William Street, Strand.

MR. G. DEPRUNET.—We are not aware that the the Tincture of Boldo mentioned in our last can be obtained in London. Try at some of the leading houses—Squire's, Savory Moore and Co.'s, Corby's, Bell's, &c. We will also try to ascertain, and let you know per post.

**DOCTORS AND WORKING MEN.**—In the Antipodes, as at home, the working classes are pushing their demands for high wages and little for it to the extreme. On Monday the *Times* published an extract from a private letter of a practitioner in Australia, which we reproduce; it is this: "I have to attend working men's clubs, and these clamorous advocates for eight hours a day and high wages don't scruple to condemn us doctors to fourteen hours a day, and pay 3s. a week to attend themselves and their families up to 18 years of age." But then, of course, doctors were made for work, and working men to skulk.

## THE LONDON SOCIETIES.

WEDNESDAY, Oct. 28th.—Hunterian, 8 p.m. Mr. Hutchinson, "On the Reasons for considering Rheumatism a Disease of the Nervous System."

MONDAY, Nov. 2nd.—The Medical. The first general meeting.

TUESDAY, Nov. 3rd.—Pathological, at 8 p.m.

## BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

A Practical Treatise on Eczema. By McCall Anderson, M.D.

London: J. and A. Churchill.

Pathological Anatomy of the Nervous Centres. By E. L. Fox, M.D.

London: Smith, Elder, and Co.

The Indian Medical Officer's Vade Mecum. By C. R. Francis, M.B.

Calcutta: Wynnan and Co.

Report of the Geographical Distribution of Fever. By Alfred Haviland, F.R.C.S.

Selected Remedies. By E. A. Kirby, M.D.

The Shipwrecked Mariner.

Persecution for Opinion in Medicine.

Note sur un Moyen Simple de distinguer la Mort Vraie de la Mort Apparente. Par le Docteur Ange Monteverdi.

El Anstero Anatomico Espanol. El Movimiento Medico. El Pabellon. La Tribune Medico. Journal de Therapeutique. The Clinic, Le Courier Medico. Guy's Hospital Gazette. Students' Journal. Irish Hospital Gazette, &c., &c.

## VACANCIES.

Middlesex Hospital. Resident Physician's Assistant and a Resident Obstetric Assistant. Applicants must address Mr. H. M. Evans, at the Hospital. (See Advt.)

St. George's, Hanover Square, Dispensary. Resident Medical Officer. Salary, £150 per annum, with residence. Candidates must send copies of testimonials with their applications to the Secretary, Mr. Leah, 73 Park Street, London, W. (See Advt.)

Royal Free Hospital, London. Junior House Surgeon, for a term of six months. Board and residence provided. (See Advt.)

Jersey General Dispensary. Resident Visiting and Dispensing Medical Officer. Salary, £150 per annum. Apply to the Rev. F. Le Feuvre, Jersey.

Carmarthen Infirmary. Resident Medical Officer. Salary, £100 per annum, with board and lodgings. Address Mr. Howells, King Street, Carmarthen.

Central London Ophthalmic Hospital. Assistant Surgeon. Honorary. Hastings Infirmary. Assistant Surgeon. Particulars of the Secretary.

York County Hospital. House Surgeon. Salary, £100 per annum, with board and lodging. Address the Secretary.

Towcester Union. Medical Officer. Salary, £80 per annum, exclusive of fees. Applications to the Clerk of the Guardians.

North Wales Lunatic Asylum. Medical Superintendent. Salary commencing at £250, with house. Full particulars of Mr. J. Robinson, Denbigh.

Santiago, Chili. Physician to the Insane Hospital. Salary, £600 per annum, with board, lodging, and travelling expenses. Appointment for four years.

## APPOINTMENTS.

BARTON, J. E., M.R.C.S.E., L.R.C.P.Ed., Assistant Medical Officer to the Surrey County Asylum at Brookwood.  
 BOTCH, J. W., M.B., L.R.C.S.I., Medical Officer, &c., for the Stillorgan Division of the Blackrock and Stillorgan Dispensary District of the Batdown Union, co. Dublin.  
 CARTWRIGHT, J. A. T., M.R.C.S.E., Medical Officer for the Leinwardine District of the Ludlow Union.  
 CLAYTON, N. G., L.R.C.P.Ed., a Sanitary Officer for the Galway Urban Sanitary District.  
 COLGAN, H., L.R.C.S.I., Superintendent Medical Officer of Health for the Kingstown Urban Sanitary District.  
 DAVIES, F., M.R.C.S.E., Medical Officer for No. 10 District (the Workhouse) of the Brentford Union.  
 DAVIES, R., jun., L.R.C.P.Ed., L.F.P. & S. Glas., House Surgeon to the Cardovanahire and Anglesey Infirmary, Bangor.  
 FENN, E. H., M.R.C.S.E., Senior House Surgeon to the Middlesex Hospital.  
 GREALY, F., L.R.C.P.Ed., a Sanitary Officer for the Galway Urban Sanitary District.  
 HADON, W. E., L.R.C.P.L., M.R.C.S.E., Resident Surgeon to the General Infirmary, Bedford.  
 HARRISON, J., M.D., Superintendent Medical Officer for the Roscommon Rural Sanitary District.  
 HAWTHORNE, J., L.R.C.S.Ed., Superintendent Medical Officer of Health for the Banbridge Rural Sanitary District.  
 HAY, F., M.D., M.B., C.M., Medical Officer for the Hainton District of the Louth Union, Lincolnshire.  
 HIND, A., L.R.C.S.Ed., Medical Officer for the Barton District of the Luton Union.  
 JAMES, A., M.B., C.M., House Surgeon to the Liverpool Infirmary for Children.  
 JOHNSON, B., M.D., Superintendent Medical Officer of Health for the Middleton Rural Sanitary District.  
 KEMP, J. R., M.R.C.S.E., Resident Medical Officer to the Atkinson-Morley Convalescent Hospital, Wimbledon.  
 KENNEDY, D. M., M.D., Hon. Medical Officer to the Liverpool North Dispensary.  
 KIDD, A., M.D., L.K.Q.C.P.I., Superintendent Medical Officer of Health for the Ballymena Rural Sanitary District.  
 LARKIN, C., L.R.C.P.L., M.R.C.S.E., House Surgeon and Secretary to the Tunbridge Wells Dispensary and Infirmary.  
 LANE, W., M.D., Superintendent Medical Officer of Health for the Newtownmavady Rural Sanitary District.  
 LEE, B. J., L.S.A.L., Medical Officer for the North Wingfield District of the Chesterfield Union.  
 MURRAY, F. R., L.R.C.S.Ed., L.K.Q.C.P.I., Junior House Surgeon to the Birkenhead Borough Hospital.  
 NEWLAND, J. F., L.K.Q.C.P.I., a Sanitary Officer for the Kingstown Urban Sanitary District.  
 NOLAN, J. J., L.R.C.S.I., Superintendent Medical Officer of Health for the Ballina Rural Sanitary District.  
 O'CONNOR, M. P., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer, &c., for the Galbally Dispensary District of the Mitchelstown Union, co. Cork.  
 O'FLAHERTY, J., L.R.C.S.I., a Sanitary Officer for the Kingstown Urban Sanitary District.  
 O'KELLY, M. T., L.R.C.S.I., Superintendent Medical Officer of Health for the Celbridge Rural Sanitary District.  
 OSBORNE, J. A., M.D., Superintendent Medical Officer of Health for the Milford Rural Sanitary District.  
 RAWSON, E. A., M.B., C.M., L.R.C.S.I., Superintendent Medical Officer of Health for the Carlrow Rural Sanitary District.  
 SCOTT, R., M.B., C.M., House Surgeon to the Dumfries Royal Infirmary.  
 SHAW, W., M.D., Superintendent Medical Officer of Health for the Lurgan Rural Sanitary District.  
 SWAN, T., M.D., L.R.C.S.I., Superintendent Medical Officer of Health for the Abbeyleix Rural Sanitary District.  
 THORP, G., M.B., Superintendent Medical Officer of Health for the Lis-towel Rural Sanitary District.  
 TURNER, H., M.R.C.S.E., Medical Officer for No. 8 District of the Norwich Union.  
 WILLS, T. M., F.R.C.S.I., L.K.Q.C.P.I., Hon. Surgeon to the Bootle Borough Hospital.

## Marriage.

SMITH—NOAD.—On the 22nd inst., at Wokingham, Berks, H. Alder Smith, F.R.C.S., of Christ's Hospital, London, to Frances, eldest daughter of G. W. Noad, M.D.

## Deaths.

DUFF.—On the 21st September, at Mandalay, India, C. M. Duff, M.D., Deputy Surgeon-General British Burmah Division.  
 DUFFIN.—On the 17th October, E. Willson Duffin, M.D., F.R.C.S.Ed., of Devonshire Street, Portland Place, aged 74.  
 GROOM.—On the 8th October, Henry George, L.S.A.L., of Kilton-Lindsey, Lincolnshire, aged 72.  
 HAVENS.—On the 18th October, at Donyland Hall, Co. Chester, Philip Havens, M.R.C.S.E., aged 69.  
 RUDGE.—On the 8th October, Henry Rudge, Surgeon, of Leominster, aged 76.  
 SHIELL.—On the 19th October, at Enniscorthy, Thomas Wildridge Shiel, A.B., M.B., T.C.D., L.R.C.S.I., Resident Medical Superintendent to the Wexford County Lunatic Asylum, eldest son of the late William James Shiel, M.D., of Clonmel.  
 TOBIN.—On the 20th October, at the Imperial Hotel, Torquay, of consumption, J. J. Tobin, M.D., of Waterford, aged 28.

## ROYAL COLLEGE OF SURGEONS, EDINBURGH.—

At the Annual Meeting of this College on the 21st inst., the following Office-bearers were elected for the ensuing year:—

PRESIDENT—James Simson, M.D.  
 TREASURER—John Gairdner, M.D.  
 SECRETARY—Robert Omond, M.D.  
 LIBRARIAN—Archd. Inglis, M.D.

## PRESIDENT'S COUNCIL—

James S. Combe, M.D. | William Walker.  
 Andrew Wood, M.D. | Henry D. Littlejohn, M.D.  
 James Dunsmure, M.D. | Patrick H. Watson, M.D.  
 Ex-Off.—John Gairdner, M.D.

## EXAMINERS—

Archibald Inglis, M.D. | David Wilson, M.D.  
 James Dunsmure, M.D. | John Smith, M.D.  
 Peter David Handyside, M.D. | Argyll Robertson, M.D.  
 James D. Gillespie, M.D. | Joseph Bell, M.D.  
 Henry D. Littlejohn, M.D. | Thomas Annandale.  
 Patrick Heron Watson, M.D. | William Stephenson, M.D.

## ASSESSORS—

William Brown. | John Gairdner, M.D.  
 James Spence. | William Walker.

CONSERVATOR OF MUSEUM—James B. Pettigrew, M.D.

CLERK—James Robertson.

OFFICER—John Dickie.

ASSISTANT TO CONSERVATOR—James Grandison.

**MEDICAL—WANTED,** an ASSISTANT to the APOTHECARY PROFESSION of two or three years' standing, who understands the Compounding and Dispensing of Physician's Prescriptions.—Apply to ALEX. BRICE, Armagh.

**IRISH PRACTICE.**—A Medical Gentleman can be secured in an easily worked Practice, realising at present £300 a year, but which can be immediately doubled. Good house, office, &c., at low rent. Satisfactory reasons for present incumbent leaving. Terms moderate.—Apply MEDICUS, 23 Ely Place, Dublin.

**ST. GEORGE'S, HANOVER SQUARE, DISPENSARY,** 59 MOUNT STREET, GROSVENOR SQUARE.—The office of RESIDENT MEDICAL OFFICER is vacant. Salary, £150 per annum, with residence. Candidates are requested to send in their applications, accompanied with testimonials, to the Secretary, Mr. G. H. LEAH, Jun., 73 Park Street, W., on or before SATURDAY, OCTOBER 31st, who will give all information required as to the position and duties. Every candidate must be a Member of the Royal College of Surgeons and a Licentiate of the Apothecaries' Company.

**THE MIDDLESEX HOSPITAL, W.—NOTICE IS** HEREBY GIVEN that there will be vacancies for a RESIDENT PHYSICIAN'S ASSISTANT, and for a RESIDENT OBSTETRIC ASSISTANT, on the 1st NOVEMBER next. Candidates possessing the necessary legal qualifications are requested to send in their applications to the undersigned by 12 o'clock on SATURDAY, the 31st inst. Oct. 17, 1874. By order, H. M. EVANS, Sec. Supt.

## ROYAL FREE HOSPITAL, GRAY'S INN ROAD.—

There is a vacancy for a JUNIOR HOUSE-SURGEON to this Hospital. Candidates, who must be Graduates in Medicine of one of the Universities, or Members or Licentiates of one of the Colleges of Surgeons of the United Kingdom, and registered under the Medical Act, are requested to send in their testimonials to the Secretary on or before WEDNESDAY, 28th OCTOBER. The appointment will be made for six months only, but the holder will be eligible for re-election. Board and residence are provided in the Hospital.

JAMES S. BLYTH, Secretary.

## MALVERN COLLEGE.

This COLLEGE contains TWO DEPARTMENTS—the CLASSICAL and the MODERN. There is also a Preparatory LOWER SCHOOL. There are Boarding Houses within the College Grounds, held by the Head Master and others of his Staff; a Gymnasium, &c.

Board and Tuition under 14, £80; over 14, £90. Non-shareholders pay an extra fee of £6. Special advantages for Sons of Clergymen and Home Boarders.

For further information apply to the Rev. ARTHUR FABER, M.A., Head Master, late Fellow and Tutor of New College, Oxford.

The Examination for Scholarships and Exhibitions on December 22nd and 23rd.

## BLOOMFIELD RETREAT,

Morehampton Road, Donnybrook.

**FOR PERSONS SUFFERING from DISORDERS of the MIND.** Under the Superintendence of a Committee of Members of the Society of Friends.

There are at present a few vacancies for first-class patients (Ladies or Gentlemen) in the above Institution.

For terms or other particulars, application to be made to the Superintendent at the Institution.

Medical Attendant: JAMES H. WHARTON, Esq., M.B., F.R.C.S.I., 28 Upper Merrion Street. Consulting Physician: WILLIAM STOKES, Esq., M.D., Regius Professor of Physic in the University of Dublin, 5 Merrion Square, North.

**CITY OF DUBLIN HOSPITAL, UPPER BAGGOT STREET.**

**Physicians:**  
HAWTREY BENSON, M.B. Univ. Dub., F.R.C.S.I., L.R.C.S.I.  
J. MAGEE FINNY, M.B. Dub., F.R.C.S.I., Demonstrator Trinity College.

**Surgeons:**  
JOLLIFFE T. TUFNELL, F.R.C.S.I., Ex-Regius Professor of Military Surgery, and President Royal College of Surgeons.  
HENRY GRAY CROLY, F.R.C.S.I., L.K. & Q.C.P.I., Senior Demonstrator of Anatomy, Royal College of Surgeons.  
WILLIAM I. WHEELER, F.R.C.S.I., M.D. Univ. Dub., L.K. & Q.C.P.I. Demonstrator of Anatomy, Royal College of Surgeons.  
ARTHUR BARKER, L.R.C.S.I., Demonstrator Royal College of Surgeons.

**Ophthalmic and Aural Surgeon:**  
LOFTIE STONEY, M.D., F.R.C.S., Demonstrator of Anatomy.

**Consulting Physicians:**  
Professor APJOHN, T.C.D., and CHARLES BENSON, M.D., Ex-Professor of Practice of Medicine, Royal College of Surgeons.

**Consulting Surgeon:**  
WILLIAM HARGRAVE, M.D., F.R.C.S.I., Ex-Professor of Surgery, Royal College of Surgeons.

**Consulting Ophthalmic Surgeon:**  
ARTHUR JACOB, M.D., Hon. T.C.D., F.R.C.S.I., Ex-Professor of Anatomy and Physiology, Royal College of Surgeons.

The WINTER SESSION commences in OCTOBER. The SUMMER SESSION commences in MAY.

Special Wards, under the care of Dr. LOFTIE STONEY, are appropriated for the reception of Ophthalmic and Aural cases, and a distinct course of Lectures on Diseases of the Eye and Ear (including Operations) is delivered, for which a Certificate is given.

There is a ward exclusively for Children, affording ample opportunities of studying the Diseases of early life.

Connected with the Hospital is an extensive daily Dispensary, at which the Pupils are allowed to perform the minor operations, and are rendered familiar with the details of Dispensary Management and the Art of Prescribing.

The "Purser Studentship," of £90 per annum (with apartment), founded by William A. Purser, Esq., L.R.C.S.I., a former Pupil of the Hospital, is open to all Students through the medium of Competitive Examination, for which a special Certificate is given, if merited, and numerous Medals and Prizes are awarded in Medicine, Surgery, and Ophthalmology.

The Drummond wing, for Fever and other Contagious Diseases, affords full opportunity for studying these branches of Medicine.

Instruction in Practical Pharmacy is given in the Compounding Department. Fee for Total Hospital Attendance, Twenty Guinea; Nine Months, Eight Guinea; Six Months, Six Guinea; Summer Three Months, Three Guinea.

For further particulars apply to Dr. WHEELER, Hon. Sec., 56 Pembroke Road, between Three and Four o'clock, or at the Hospital between Ten and Eleven o'clock a.m.

**SPECIAL NOTICE.—FURTHER REDUCTION OF ONE SHILLING PER GROSS, AND 2½ PER CENT. DISCOUNT FOR PROMPT CASH.**

**PLEASE NOTICE—SUPERIOR QUALITY.—SAMPLES FREE.**

**THE NORTH LONDON GLASS BOTTLE COMPANY**

(I. ISAACS and Co.)—WORKS, LONDON AND YORKSHIRE.

Warehouses, 25 and 24 Francis st., Tottenham-court road, London, W.O.

List of prices for NEW MEDICAL GLASS BOTTLES and PHIALS of superior manufacture:—

6 and 8 oz., any shape, plain or graduated	Clear blue	(10s. 6d. per gross.
3 and 4 oz., ditto	tinted	(9s. 6d. "
1 oz. white moulded phials ditto	Of a very	(5s. 0d. "
1 oz. ditto	superior	(6s. 0d. "
1½ oz. ditto	quality.	(7s. 6d. "

Prompt attention to Country Orders. Terms, cash on receipt of goods, and 1s. each for package. Goods delivered free within 7 miles. P.O.O. to be made payable to I. ISAACS and Co., at the Post-office, Tottenham court road.—BANKERS, London and Westminster Bank.

Established nearly 100 years.

**SPECIAL NOTICE.—Further reduction of 6d. per Gross on all sizes and 2½d. per cent. discount for prompt cash.**

**ISLINGTON GLASS BOTTLE COMPANY WORKS.**

LONDON and YORKSHIRE.—This Company supply only the very best MEDICAL GLASS BOTTLES and PHIALS at the lowest prices. London Warehouses, 19 Bread-street-hill, Upper Thames street, City, E.O., and 28 Copenhagen street, Islington. H. HARRIS and Co., Proprietors. Established upwards of 80 years.

6 and 8 oz., any shape, plain or graduated	Clear blue	(11s. 0d. per gross
3 and 4 oz., ditto	tinted	(10s. 0d. "
1 oz. white moulded phials ditto	Of a very	(5s. 0d. "
1 oz. ditto	superior	(6s. 0d. "
1½ oz. ditto	quality.	(7s. 6d. "

Immediate attention to country orders. No remittance required until the goods are received. Country Packages 1s. each. Goods delivered free within 7 miles. Post office orders payable to H. HARRIS and Co. at the Chief Office, London.—Cheques to be crossed Alliance Bank.

N.B.—Orders sent to either establishment will have prompt attention

Established 1848.

**PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.**

50 LINCOLN'S INN FIELDS, W.C.

**J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.,**  
&c. (KING'S COLL.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

**COMPETENT ASSISTANTS** provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

**PRACTICES AND PARTNERSHIPS NOW OPEN** for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

**Z 48.** In a pleasant town in the Midland District, a PRACTICE for TRANSFER upon easy terms, the vendor having accepted a Partnership elsewhere. The actual receipts have averaged about £850 a year, and there is great scope for extension, as the practice has not been actively pushed. The connection has been in the present hands about eight years, and is believed to be wholly transferable to a suitable gentleman. There are about 100 cases of midwifery in the year, chiefly at 1 ls. and upwards. The patients are middle-class. A small premium would be accepted from a doubly-qualified man of experience.

**Z 47.** LONDON SUBURB, N.W. In consequence of serious illness, the Incumbent of an OLD-ESTABLISHED PRACTICE desires to secure an immediate SUCCESSOR. Receipts, £600 a year; they were formerly much larger, and there is great scope for increase. The books have been well kept, and the fullest investigation is courted. No midwifery under £1 1s. Appointments have been declined. The residence is very conveniently situated, near one of the main arteries of traffic; it contains ten rooms and surgery. Rent, £50. An effective introduction can be given.

**Z 46.** EXCELLENT NUCLEUS in a northern town in a picturesque district. A doubly-qualified gentleman of Catholic opinions would be sure of success. £250 would purchase everything as it stands.

**Z 45.** LONDON, W. WELL-ESTABLISHED PRACTICE, yielding on an average between £300 and £400 a year, with great scope for increase. Appointments, £100. No horse, carriage, or assistant necessary. Midwifery, £1 1s. and upwards. Good corner house, containing ten rooms. Rent, £60. Introduction as desired. For a gentleman commencing practice, the opening is an unusually advantageous one.

**Z 43.** In consequence of severe illness the Incumbent of a PRACTICE which formerly yielded £800 a year desires to introduce a SUCCESSOR. No premium required unless at least £400 is booked in the first year. An effective introduction can be given.

**Z 42.** In a thriving agricultural district, a WELL-ESTABLISHED TRANSFERABLE PRACTICE, yielding in actual receipts £1,100 a year. Advancing age the sole cause for retirement. Books open to the fullest investigation, and the highest references given. Appointments, worked with little trouble, produce £62 a year. The residence has been for many years associated with the Practice; it contains ten rooms, with detached surgery and consulting-rooms, stabling, and large garden. Rent, £42.

**Z 40.** PRACTICE and APPOINTMENTS. Receipts upwards of £800 a year. Appointments over £500. About £10 a week is taken in cash. Patients middle-class. Ill-health the cause of retirement. Good house. Rent £36. Premium, £300 down and £100 secured.

### ON THE SCIENTIFIC AND EMPIRICAL INVESTIGATION OF EPILEPSIES.

By J. HUGHLINGS JACKSON, M.D., F.R.C.P.,

Physician to the Hospital for the Epileptic and Paralysed, and to the London Hospital.

#### CHAPTER II.

##### DEFINITION.

My definition of the word Epilepsy has already been given by implication, but I must give it formally before I go further.

Epileptic discharges are occasional, abrupt, and excessive discharges of parts of the cerebral hemisphere (paroxysmal discharges).

Let me show another side of the definition. In each Epilepsy there is an area of grey matter in some part of the cerebrum which is so abnormally nourished that it occasionally reaches very high tension and highly unstable equilibrium. It occasionally discharges, or it is discharged by some eccentric irritation or during some general bodily disturbance, as, for example, that attending fright.

After its discharge the portion of grey matter once more, by continuous nutrition, reaches high tension, and is again ready for discharge. It will be gathered that the "discharging lesion" is supposed to be a persistent and also a local lesion. For the definition I have given, it matters not as to the locality of the lesion, or, otherwise expressed, it matters not what particular symptoms result from the discharge; they may be sensory or motor—for example, they may be such as red vision (a) or convulsion.

(a) We have already in Chap. I., Part 2, page 349, spoken of the double use of the word "sensation," and have insisted that sensations in the sense of "states of mind" occur during excitation of motor nerves and centres. The word "red" is really a name for a mental state. The proper comparison is not betwixt the sensation of redness (mental state) in an epileptic discharge and convulsion (physical state). This would be to compare two things which are utterly different. The comparison, physiologically,

Difference in the phenomena depends on difference in the seat of the unstable grey matter. A list of epilepsies will be given further on. But it may now be mentioned that I believe epilepsies in which the phenomena are sensory, or in which strong development of sensation is the initial phenomenon, depend on discharges beginning in the posterior part of the brain; whilst epilepsies in which development of movement is the chief and earliest thing, depend on discharges beginning in the anterior part of the brain. (b)

Let us consider the subject from another point. We have, so far as is practicable, to study epilepsies as departures from healthy states. We must, then, give a brief sketch of healthy nervous discharges before we speak in more detail of epileptic discharges.

Where there is grey matter there discharge occurs during healthy functional exercise. This is a truism. If I move my arm there is of necessity an expenditure of force. This is not in muscles only, nor in nerves only. It must be in some nervous centre or centres. In the movement of any part, however limited, many muscles serve. Duchenne says that no man can move a muscle singly, except perhaps in the face. Evidently it follows from this fact that there is in every movement a discharge of a part where movements are co-ordinated. This is saying that the discharge is of a nervous centre that is of grey matter.

would be betwixt abnormal excitations of optic centres and nerves and abnormal excitations of motor centres and nerves. We cannot observe the results of excitation of "sensory" nerves and centres. We have to rely on what the patient tells us, and, of course, he can only tell us of what occurs before he loses consciousness; we can observe the results of excitation of motor centres and nerves after he has lost consciousness. The statements in the text and subsequent similar statements are, however, conventionally correct, and yet from a scientific point of view too absurd to be misleading.

(b) This is in accordance with an old conclusion that the Anterior is the chiefly Motor, and the Posterior the chiefly Sensory part of the Cerebral Hemisphere. I put forward this view some years ago, and it is a matter of satisfaction to me to find that it accords with certain of Ferrier's conclusions from his brilliant experiments. I shall have many times to refer to this topic, and will therefore give quotations bearing on it in an Appendix to this Chapter.

The above remarks on healthy nervous discharges do not refer only to what are arbitrarily distinguished as physical processes—to discharge of lower centres—they refer in principle to mental states also, or rather, of course, to their physical side. They apply to discharges of the highest centres. The nervous arrangements forming the substrata of mind are only in great degree different from the nervous arrangements of the pons or spinal cord. And when we think or speak, as well as when we walk, there are nervous discharges. I must, however, consider this matter in some detail, because I wish to show that epileptic discharges are discharges of parts of the chief organ of mind.

The anatomical unit of a nervous organ is not a cell or a fibre, or a compound of both. Such a compound is only the morphological unit. The anatomical unit is a *sensori-motor process*. It is not an afferent (sensory) process only, nor a motor process only, but these two put in a particular relation by cells of grey matter. It is just as the unit of speech is not a word, nor a series of words, but a proposition. The anatomical unit represents, either directly or indirectly, a peripheral impression associated with a muscular adjustment. The peripheral impression may be either on the surface of the body, or in its interior—epi-peripheral or ento-peripheral (Spencer). The surface impressions vary from those most general of mere contact of ordinary objects with the ordinary surface of the body to those so special as retinal impressions. The impressions from the interior vary widely also. They are from muscles, viscera, &c., and form the chief part of what are called Systemic Sensations. The movements associated with these two classes of peripheral impressions vary similarly.

In the lower parts of the nervous system it is plain that surface impressions are put in relation with particular muscular adjustments by nerve centres. The units of composition of the lower centres are evidently sensori-motor processes. They represent impressions and movements *directly*. The experiments on the cord to prove reflex actions illustrate this well. What is, anatomically, a sensori-motor process is physiologically a reflex action necessarily implying central discharge. But I submit that the unit of composition of the very highest centres is the same. (See quotations from Laycock and Spencer, Chapter I., Part 2.) The highest centres can only represent the impressions and movements which the lower centres represent directly.

I will state the above in other words, already used. In the lower centres there is a direct adjustment of few and simple movements to few and simple peripheral impressions. In the very highest (a) centres there is an adjustment of exceedingly special movements (representing movements of the whole organism) to the most special of impressions from the environment.

So far for the anatomical units. Now for the physiology of them—that is, their conditions of discharge. There are discharges of the highest sensori-motor processes when we think, just as there are of lower processes when we walk. Let us take a convenient example of discharges occurring in mental operations. There is internal speech and external speech. There are central discharges when I speak internally, just as there are

when I speak aloud. That in the former there are no outward effects makes no essential difference; there is a central discharge in both cases, and of the same series of processes. It is absurd to suppose that different series of nervous processes are engaged when I say "gold is yellow" to myself and when I say it aloud. There is a difference in the strength, and consequently in the spreading, of the discharge. The discharge is slight, and limited to the centre when I speak internally; it is stronger, and spreads from the centre first excited, to lower centres and to the muscles when I talk aloud. So far for healthy discharges.

Wherever there is nervous tissue disease may occur. Now, disease can lead to either of two kinds of changes in this tissue. It may lead either to destruction of function of nerve tissue, or to changes of instability of nerve tissue—either to an inability to discharge, or to an over-readiness to discharge. These are the two divisions of abnormal functional changes in nerve tissue, the simple and obvious ones, of "loss of function" and "over-function;" there are destroying lesions and discharging lesions (instability). Every nervous symptom depends on one of these two abnormal functional states. The nervous changes in epilepsy, as I use the word, belong to the second division. There are in epilepsies abnormal discharges of areas of highly unstable grey matter. *These discharges are to be looked on as gross exaggerations of healthy nervous discharges.* Our next step, therefore, is to consider the differences betwixt healthy discharges of the sensori-motor processes of the brain and epileptic discharges of them. First let me make a brief re-statement.

I believe that epileptic discharges which result in spasm of muscles are excessive discharges beginning in convolutions—that is to say, that they are discharges beginning in parts of the chief organ of mind. I think, too, that discharges of the very same parts occur during healthy mentation. (a) Let us see how these two seemingly contradictory views really harmonise. Let us state a case. We have already spoken of internal and external speech; we now take another series of nervous processes.

Suppose that a limited (b) part of the brain is the seat of visual ideas. The material basis of these ideas is, of course, made up of nerve cells and fibres. But this is, be it remarked, not a statement in either anatomy or physiology, and is of no use for our present purpose. The anatomical statement is, that the substrata of these ideas represent, or rather re-represent, retinal impressions and ocular movements. (Without an element of movement there would be no representation of size or figure.) They are fundamentally like the nervous arrangements for ordinary reflex action; they are sensori-motor processes. We will call them retino-ocular processes. So far for anatomy. Now for physiology. The study of the degrees and conditions of excitation or discharge of nervous processes is a physiological study. We will first consider what occurs in health when we have visual ideas—that is, when we see or remember objects.

Most of our ideas are latent. The equivalent physiological statement is that the anatomical elements (sensori-motor processes) are unexcited. But we speak now of ideas actual and correspondingly of their anatomical substrata as being excited or discharged. Now, we have in health vivid ideas and faint ideas. We see objects and

(a) Observe two differences of degree: In the ordinary reflex action the movement follows the afferent incitation with, no or with little, delay. In the highest centres, if my speculation as to the motor and sensory regions be correct (see foot-note, p. 389, and Appendix No. 2), the movement will not be immediate. For the speculation assumes that there is in the highest centres wide geographical separation, and thus probably delay. Again, in the lowest reflex actions some particular movement is fatally necessary, and occurs rapidly after some particular impression. But in the highest centres it may be that there is not this absolute connexion. The organisation is not complete. Thus, after seeing a red circle and a blue square we can think of a red square and of a blue circle. The sensory and motor elements which enter into the physical side of our perceptions of simple objects can be transposed. These statements appear to me to accord with certain views of Herbert Spencer. (See Appendix No. 1).

(a) Since delirium, hallucinations, &c., are but caricatures of healthy mentation, we may put the statement in the text in another form which is nearly equivalent. A convulsion is, I think, as much a symptom of disease of the organ of mind as delirium is.

(b) This supposition is legitimate for mere illustration, although I do not believe in such narrow localisations; and, as before stated, I think there is in the cerebral hemisphere a wider separation betwixt the motor and sensory elements of sensori-motor processes than in the lower centres; the anatomical substrata of visual ideas must contain elements representing movements as well as impressions. As an illustration, the supposition in the text is convenient and legitimate.

The word Mentation, used in the text, was, I believe, introduced by Mr. Metcalfe Johnson.

we can think of them afterwards. First for the vivid ideas. When we actually see and recognise external objects, we have *vivid* visual ideas. There is then strong excitation of the retina, thence to the highest centres in the cerebrum, and back to the ocular muscles. There is complete sensori-motor (let us say retino-ocular) action. If we recognise an object, the very highest centres must be engaged; for Recognition is, in common with Classification, a modified form of reasoning (Spencer's "Psychology," vol. ii, p. 127). (a) The process described is what is fundamental, however many intermediate centres we may like to suppose betwixt the afferent nerves (optic nerves and retina) and efferent nerves to the ocular muscles. Next for faint ideas. When we have faint visual ideas (think of objects when they are absent—"recollect" them, &c.) there is slight or nascent excitation (discharge) of those highest centres to which, when we actually saw the objects, the retinal impressions came, and from which the impulses to the ocular muscles departed. In other words, essentially the very same physiological process occurs in the two cases, and it occurs in the same anatomical series during thinking of or remembering objects as occurs during actually seeing them. I say essentially, as there are two differences of degree. In thinking of objects the central discharge is (1) slight, and (2) limited to the centre. In actually seeing them it is strong, and spreads from periphery to the centre and from centre to periphery. (b)

(a) As before remarked, retinal impressions and ocular movements are signs of tactual impressions and movements and of locomotor movements. I may here reproduce a part of a paper, on "The Localisation of Movements in the Brain" (*Lancet*, February 15, 1873), bearing on the motor part of the mechanism of this symbolisation:—

"Both in hemiplegia and in convulsions beginning unilaterally we note certain associations. The most important is the association of affection of certain movements of the eyes with affection of those of our limbs. Significantly (and in accordance with the principle spoken of throughout this paper) the movements of the eyeball which are first affected are the *lateral*. We can overcome a prism of from 20° to 30° with its base placed outwards, and one of 6° to 8° with its base placed inwards; but few persons can overcome more than a prism of 1° or 2° with its base turned upwards or downwards. There is then greater variety or independence in the lateral movements of the eye. (The internal rectus is the strongest of the ocular muscles.) In association with this greater independence of the lateral movements we may note that the sensibility of the retina diminishes less rapidly outwards than upwards and downwards. That the movements of our chief tactual organs should have close and direct associations in the *highest* nervous centres with certain movements of the eyes is what one would expect if, as Spencer says ("Psychology," vol. i, p. 358), 'tactual impressions are those into which all other impressions have to be translated before their meanings can be known.' I suppose visual impressions and ocular movements may be said to 'stand for' tactual impressions and movements in the sense that the strong excitation of the nervous processes of the former leads to *faint* excitation of those of the latter (movements of the hands, &c.) The study of cases of hemiplegia and convulsion shows us, not only that there is an association, but the *order* in which eye movements and limb movements are associated."

In the same paper I put forward the speculation that movements of the eyes in divergence and convergence (upwards and downwards) are represented in the cerebellum. Ferrier's researches show that ocular movements are, as I inferred, represented in the cerebellum.

(b) The following are quotations from the parts of Spencer's "Psychology" referred to (p. 349) when speaking of the physical processes occurring in recollection:—

"In brief, those *vivid* states of consciousness which we know as sensations, accompany direct and therefore *strong* excitations of nerve centres; while the *faint* states of consciousness which we know as remembered sensations, or ideas of sensations, accompany indirect, and therefore *weak* excitations of the same nerve-centres" (no italics in original).—"Principles of Psychology," vol. i, p. 124.

"In a voluntary act of the simplest kind we can find nothing beyond a mental representation of the act, followed by a performance of it—a rising of that incipient psychical change which constitutes at once the tendency to act and the idea of the act into the complete psychical change which constitutes the performance of the act, in so far as it is mental. Between an involuntary movement of the leg and a voluntary one, the difference is that, whereas the involuntary one occurs without previous conscious-

ness of the movement to be made, the voluntary one occurs only after it has been represented in consciousness; and as the representation of it is nothing else than a weak form of the psychical state accompanying the movement, it is nothing else than a nascent excitation of the nerves concerned preceding their actual excitation" ("Psychology," vol. i, p. 497).

Now for the epileptic discharge. It must never be forgotten that it is an excessive discharge. Not only is it very much more excessive than the discharges which occur when we have faint mental states, but it is very much more excessive than those occurring in vivid mental states. Besides being excessive, it is of a limited part of the brain. It is rapid, and it is soon over. In such excessive discharges as the epileptic discharge of our supposed centre for visual ideas there could not be a development of ideas of objects either of such ideas as occur in health or of such as occur in delirium and insanity. We have, however, to do with what occurs physically. We have to do with epileptic discharges of those *sensory-motor processes* which are the anatomical side of ideation. There is in some cases of epilepsy evidence of excessive excitation of parts of the brain representing retinal impressions, as the patient has clouds of colour before his eyes. There often occurs also, as part of a larger fit, that clotted mass of movements of the ocular muscles which we call spasm (for example, strong lateral deviation of the eyes). In the first case there is, I believe, a sudden and excessive discharge of a limited part of the cerebral hemisphere, which contains crowds of the sensory element, and in the second of the motor element, in the highest processes of the series for visual ideas. The discharge in the epilepsy being very strong, rapidly spreads down to the lower centres, and by these to the muscles, and thus produces innumerable ocular movements at once, or rather jams innumerable ocular movements into one stiff struggle.

The same reasoning applies, *mutatis mutandis*, to the discharge of the anatomical substrata of tactual ideas, the chief of which are impressions of surface of the fingers and adjusted movements of the hand. An epileptic discharge of the anatomical substrata of these ideas would produce numbness and spasm of the hand and arm.

Similarly, an epileptic discharge of the so-called centre for "memory of words" on the left side of the brain results, I consider, in convulsion of the articulatory muscles. For I believe, and have long urged, that the anatomical substrata of words are motor (a) (articulatory) processes. I should think, too, that an epileptic discharge of that part of the brain on the right side which corresponds to the supposed centre for words on the left would produce an essentially similar convulsion; for I believe that both sides of the brain are educated in words, but that the left is the *Leading* (b) side.

That that which is commonly described as the epileptic paroxysm is the result of a discharge of some part of the nervous system is as certain as that paralysis is the result of destruction of function of some part of the nervous system; the exaggerated movement of the convulsion could not result else. It is a truth, or truism. On the other hand, all abnormal nervous discharges are not epileptic discharges. There is, for instance, an almost continuous stream of discharges in tetanus, and there are rapidly succeeding discharges in chorea. The epileptic discharge comes on with more or less suddenness. The paroxysm is violent, and is soon over.

Briefly, the epileptic discharge differs from the other kinds of abnormal discharges above-mentioned in being paroxysmal. This is a fundamental difference never to be

ness of the movement to be made, the voluntary one occurs only after it has been represented in consciousness; and as the representation of it is nothing else than a weak form of the psychical state accompanying the movement, it is nothing else than a nascent excitation of the nerves concerned preceding their actual excitation" ("Psychology," vol. i, p. 497).

In the ideation of delirium the central discharges may be so strong that the patient believes he actually has snakes, &c., before him. In insanity, also, there is a similar exaggerated central action, but in both cases the discharge is, in comparison with the epileptic discharge, but a slight departure from health.

(a) I have urged this view for years. Until very recently I have been alone in that opinion, that is amongst physicians in this country; I am very glad, therefore, to find that Ferrier has quite independently reached a conclusion essentially similar.

(b) Here, again, I can adduce the independent confirmatory opinion of Ferrier. He calls the left the "driving" side.

lost sight of. It is as important to note the *nature* of a nervous discharge as it is to note the external region on which the discharge works its effects. More will be said on this matter later on, under the head of co-ordination. But the difference may be briefly illustrated by saying that unilateral convulsion (cerebral discharge) differs from tetanus (cerebellar discharge) not only in that a different class (a) of muscles suffers, but in that in the former there is a paroxysmal, and in the latter a continuous, although remittent discharge.

I do not deny that any part of the nervous system which contains grey matter may become unstable, and may discharge abnormally. We shall have to note, however, that some parts of the nervous system are very much more liable to become diseased than other parts, and in the brain the region in the district of the middle cerebral artery suffers more often than other cerebral regions. Further, it is not certain that abrupt and paroxysmal discharges result from disease of the lower parts of the Nervous System in Man. There are, however, certain tetaniform symptoms in children occurring along with, if not dependent on, disease of the cerebellum, to be spoken of later on.

I may now give some examples of epilepsies in accordance with my novel definition of epilepsy. A paroxysm of red vision, (b) of strong smell in the nose, a paroxysm of vertigo, of spasm of certain parts of the body, tonic followed by clonic (of the hand and forearm, of the cheek, of the foot, of the whole of one side, going on or not into universal convulsion), of coloured vision, with other initial symptoms of an attack of migraine, are all epilepsies. So also is transient loss of consciousness, or loss of consciousness followed instantly by convulsion. In each of these cases there is an abrupt and excessive discharge. It is particularly to be observed that a convulsion in which consciousness is *not* affected is under the novel definition, as much an epilepsy as one in which, as in slight *petit mal*, consciousness alone is lost there being, at any rate, no *observable* spasm. In the latter, as in the former, there is a sudden, excessive and rapid discharge of nerve tissue. Since I believe that any part of the cerebral hemisphere may become the seat of a discharging lesion, there will be all kinds of phenomena produced; and since there are supposed to be all degrees in the extent of the discharging lesion, the symptoms will vary in degree as well as in kind.

(To be continued.)

## ABSTRACT OF AN INTRODUCTORY ADDRESS

DELIVERED AT THE  
ROYAL COLLEGE OF SURGEONS IN IRELAND.

By EMERSON J. REYNOLDS, F.C.S.,  
Professor of Chemistry in the College.

GENTLEMEN,—In accordance with a time-honoured custom, we meet to-day to inaugurate a new winter session of professional study in these halls. An annual gathering such as this, honoured as it is by the presence of the heads of the college, marks for many the commencement of a great life-work and for a still larger number of us, the beginning of a new stage of progress in knowledge; while a pleasant atmosphere of hopefulness surrounds us all. But however bright the future may seem to us, much more than a passing shade must be cast over our meeting to-day, just as on the last occasion, by the remembrance that a few weeks only have elapsed since the grave closed over all that was mortal of a venerable and distinguished former Professor of this college. Need I say that the name of Dr. Arthur Jacob will long live in these halls and in the memories of all of us who had the privilege of calling him "master." Of his great intellectual activity, of his intense earnestness, and of his services to science, it would ill-become, especially in the presence of one who has given to the world an admirable biographic sketch of Jacob's life; but some of those whom I have the honour to address will

(a) Or rather, perhaps, the muscles suffer in different order. In cerebral discharges the limbs suffer first and most; in cerebellar discharges, the trunk suffers first and most.

(b) See first foot-note to this Chapter.

remember to have heard this theatre ring with cheers as the fine old man demonstrated to us the "Membrana Jacobi"—his chief anatomical discovery—and they may have also listened while he described with enthusiasm to a hospital class that peculiar form of ulcer with which his name was long associated. In care for the interests of this college—of which he was thrice President—Dr. Jacob was unwearied from the time of his appointment in 1826 to the chair now so worthily occupied by Dr. Mapother, until, as Professor Macnamara says in his biography—"Full of honours, full of years, he at last, in the unimpaired vigour of his intellect, resolved on retiring from the services of that college which he loved so well, and over which he had for so many years presided with unceasing devotion." You are all no doubt aware that during the present month a special Act of Parliament has come into operation in this country which is likely to exercise a most important influence upon the future relations of the medical profession and the public. Up to the present time the dispensary medical officers in Ireland have been, at least officially, the representatives of curative medicine only. The new Public Health Act has essentially charged them with the application of the principles of preventive medicine in addition. I heartily wish it could have secured to them larger remuneration for these added duties than they seem likely to receive. The Act is admittedly open to criticism, but the reasonable and prudent course seems to me to be to await experience in the application of its most useful enactments under the judicious supervision of the Local Government Board. When the defects in its working are fully and fairly ascertained, I think we may look with confidence for the remedy to the distinguished statesman who had charge of the measure in its passage through the legislature. But you are more nearly concerned in ascertaining the extent of the influence the new Public Health Bill in Ireland is likely to exert upon medical education in this country. I am well aware there is a wide-spread impression that this influence will be very great; but after careful consideration of the matter, I think we may safely conclude that the actual effect will be comparatively slight. When we exclude the legal and engineering questions likely to arise under the new Act, and which should be dealt with by competent lawyers and engineers, I think it will be found that no really new study need be undertaken in order to fit a man for the performance of the duties of a medical officer of health. In the words of one whose illustrious name is the highest guarantee for the statement, preventive medicine has amongst its chief objects, on the one hand, says Dr. Stokes, "the removal of the supposed causes of diseases, whether affecting individuals or giving rise to endemics or epidemics; and on the other, the employment of those measures which are to promote the physical well-being of the community." But it is clear, gentlemen, that the causes of diseases cannot be removed if they are not known, nor can the conditions of maximum health be secured to the community if we are ignorant of the relative importance of the great factors in the physical well-being of man. Hence the study of the etiology or causes of diseases, based on a large and sound knowledge of chemistry, physiology, and pathology, and aided by the information the statistician can afford, must assume a position of much greater importance than heretofore in the professional curriculum—I mean, of course, in the eyes of students. In the remarks I have hitherto made it has been almost assumed that the causes of disease are known. Now though this perhaps is true of many, it is very far from being true of the great class of epidemic diseases to which scarlatina, small-pox, yellow fever, typhus, and typhoid fever belong, though a certain class of sanitarians in their extreme dogmatism would lead you to suppose the opposite. The spread of these epidemic diseases is undoubtedly in great part due to contagion, but we are ignorant of the nature of the virus communicated by the sick person, and of the precise origin of that emanation. Here, then, is a great field for investigation open before you—great in importance as in extent. We shall pursue the subject so far as to enable you to appreciate the use we may

make of two of the so-called disinfectants I wish specially to bring under your notice to-day. If the propagation of disease be due to the scattering of living organisms, these bodies, different though they may be for different diseases, all probably agree in being extremely minute, and are perhaps to be regarded, as Dr. Parkes says, as belonging to that class of organisms which Nägeli has separated from the fungi, and which form the lowest stratum of the animate world at present known to us, such as bacteria, vibrios, &c. In dealing with epidemic disease the sanitary officer acts upon his knowledge of the fact and the theory of contagion, for he in the first instance isolates the patients as far as practicable, and then seeks to destroy the living organisms assumed to be thrown off by the affected, and liable to be carried to the healthy by the atmosphere, clothes, or other numerous means by which matter can be transported; in other words, he resorts to the use of "disinfectants" so-called. And it is chiefly to chemistry, gentlemen, that the sanitarian appeals for the means of destruction of his hypothetical "germs," and experience has proved that he does not appeal in vain, for chemistry supplies him with numerous substances more or less suitable for his purpose. Of these many are well known and freely employed both as mere deodorisers, in the sense of removing bad smells, and as disinfectants in the wide meaning of the term; but I would seek to-day to awaken your practical interest in two of the latter class which experiment has forced me to believe are amongst the most effective bodies known—my reference to them shall, however, be very brief. The first body I shall refer to is benzoic acid, and the second ozone. But you will bear in mind that any statements I make touching benzoic acid and ozone refer to their action on Bacteria, &c. Now we may destroy these organisms at ordinary temperature either by poisoning them or by a corrosive chemical action somewhat analogous to that which would take place if we were to dip an animal in a bath of aqua fortis. According to the experiments of Dr. Dougall, and my results accord closely with his, benzoic acid may be taken as one of the best types—if not the best—of the poison group, though it may be taken by man in considerable doses with impunity. Benzoic acid is superior even to carbolic acid and its homologues, and is free from their unpleasant smell, and from other disadvantages that interfere with their convenient use. I am, therefore, anxious to see this interesting and non-corrosive acid more extensively employed as a disinfectant than it has hitherto been. Benzoic acid has long been known and used in pharmacy for the purpose, amongst others, of preserving ointments from decomposition. It is a light, feathery body, as met with in commerce, and is obtained, amongst other sources, from the so-called gum benzoin by the simple process of heating. The acid, being very easily volatile, sublimes, and is condensed in snow-like flakes. The pure substance is inodorous, but when heated it diffuses an agreeable smell, owing probably to slight decomposition. Advantage can be taken of its volatility to diffuse the acid through an infected apartment, for we have only to heat gently a brick or shovel, and to throw some of the acid upon it in order to get a quantity of vapour that can be allowed to mix freely with the air of the room. Again, the acid is easily soluble in hot water, and therefore in the state of solution can be employed in washing boards, infected articles of clothing and surgical appliances, or as a solution for the spray produce employed in that remarkable system of antiseptic surgery practised with such success by Mr. Lyster, of Edinburgh. And now I turn to the second disinfectant I referred to—namely, ozone.

We possess a very delicate test from this ozone in paper saturated with a mixture of iodide of potassium and starch. When paper so prepared is acted on by ozone, iodine is liberated and its separation evidenced by the strong brown or blue colour developed. It has been long known that when this prepared paper is exposed to pure country air it is quickly discoloured, but it remained for Dr. Andrews to

prove that this effect is really due to ozone. Now, it is found that this atmospheric ozone is rarely present in the air of large towns, more especially in the neighbourhood of factories, and the reason for this clearly is that the organic and other impurities in town air destroy and, I may add, at the same time are destroyed by this ozone, which acts as a natural disinfectant. I have experimented with this body to a large extent upon the lower organisms, and can state as the result that the destructive action it exerts upon them is very great, especially if they happen to be in a somewhat dry condition. In this respect ozone appears to be greatly superior to chlorine, and in ultimate effect to the gaseous oxide of sulphur commonly called sulphurous acid. But some of you may ask what is this ozone, and I reply that it is a very active modification of oxygen, that gas upon whose presence in the atmosphere our lives depend. The partial conversion of this atmospheric oxygen into ozone is a much more simple matter than many people suppose, and I shall, in conclusion, draw your attention to several methods of ozonising air. Rather more than sixty years ago Van Marum noticed a peculiar smell produced when electric sparks are passed through the air. We know now that this smell is due to the formation of ozone during the passage of the electric discharge, and it is fairly argued that the ozone we detect in the atmosphere, and which is abundantly present after a thunderstorm, is produced by electricity. But we have ozone produced in many other ways, but particularly during certain processes of slow combustion, though a high temperature destroys ozone. I may illustrate this in the cases of the slow oxidation of phosphorus and of ether, the latter case being especially interesting, as it affords us an easy mode of ozonising a small quantity of air. The method by which we can produce large quantities of ozonised air is that in which we make the gas pass between two surfaces, in opposite electrical conditions, and with the aid of the apparatus called Siemen's induction tube, through which air is forced by means of a bellows, we can quickly ozonise the atmosphere of a large room. The actual quantity of ozone produced in all these processes is small, but its great chemical activity compensates for this. We are, however, able to store it up in a comparatively concentrated form in certain bodies which easily absorb it, such as ether, turpentine, and some of the essential oils, and these solutions are capable of producing most of the effects of ozone. I have here some ozonised ether, and I can show you that it differs materially in its action from ordinary ether; but I may, at the same time, warn you that concentrated ozone, if I may use such a term, is capable of acting, not only as an irritant to animals, but also, like most oxidisers, as a powerful bleaching agent.

#### CHEMISTRY IN ITS RELATIONS TO THERAPEUTICS. (a)

By W. HANDSEL GRIFFITHS, Ph.D., L.R.C.P.E.,

Licentiate of the Royal College of Surgeons of Edinburgh, Honorary Member of the Ontario College of Pharmacy, Librarian to the Royal College of Surgeons in Ireland, Editor for the *Edinburgh Medical Journal* of "The Monthly Reports on the Progress of Therapeutics."

THE subject which it is my privilege and pleasure to bring under the notice of the Society this evening is one which should possess considerable interest for every member of the profession of medicine. I suppose there is not one of us who does not welcome every effort towards establishing therapeutics on a scientific basis.

My present object is to direct the attention of the Society to certain recent chemico-therapeutical researches, which are of no little importance as serving in some degree to raise therapeutics from the grade of irrational empiricism to the dignity of an exact science.

Three lines of research, although as yet imperfectly prosecuted, have already borne fruit, and hold out promises of an abundant harvest; these enquiries are—1st. The chemistry of the tissues and secretions in their healthy and morbid states; 2nd. The connection between the chemical constitution and physiological action of medicinal agents, and 3rd. The chemical decomposition and alteration of drugs in the animal economy.

(a) Read before the Surgical Society of Ireland.

To the chemist undoubtedly belongs the credit of paving the way to a scientific therapeutic method. "Chemical enquiry is now finding its way into many of the remoter secrets of function, and is likely before long to establish some laws of molecular constitution which will enable us to classify unknown remedies and to explain and calculate their actions." So writes Clifford Allbutt.

The necessity of studying remedies from their chemical relation to the animal tissues is forcibly indicated by Charles Bland Radcliffe in his paper on "The Treatment of Neuralgia," read before the British Medical Association, at the Bristol meeting in 1863. He reasons thus: Nerve pain is indicative of deterioration of nerve tissue; hence phosphorus and cod-liver oil as nutrients for the nerve tissue are the appropriate remedies.

So long ago as 1841, Blake (a) attempted to frame a law to the effect that salts of isomorphous bases have in general a similar action. So far as I am aware, this was the first attempt to define a connection between chemical constitution and therapeutic action.

In 1868 Dr. W. H. Broadbent brought an extremely interesting communication under the notice of the Royal Society of London. (b) In this paper the author states that "substances chemically allied should have similar physiological and therapeutic actions, or any diversity found to exist should be capable of explanation on chemical grounds." The source of nerve-force is stated to be oxidation, and the seat of oxidation is the nervous structures. Poisons which kill by their action on the nervous system all contain nitrogen, and this element is the pivot on which the deadly influence turns. In the nervous structures carbon and hydrogen are liberated in the nascent state and appropriate the oxygen brought by the blood, and thus produce a result equivalent to exclusion of oxygen. The carbon and hydrogen are set free by the dislocating influence ("chemical tension") of nitrogen. Prussic acid affords a striking example of a poison acting in such a manner. This paper of Broadbent's is eminently suggestive, and must be regarded as a valuable contribution to the chemistry of therapeutics. I have now to ask your attention to the masterly essay of Drs. Crum Brown and Thomas Fraser, "On the Connection between Chemical Constitution and Physiological Action." (c) These investigators show that composition alone is insufficient to explain physiological action, and that constitution, by which is meant the mutual relations of the atoms in a substance, must also be taken into account. Thus, acetic acid and sugar are identical in composition, as are glycolic acid and nitrite of ethyl; again, kakodylic acid is inert, although it is perfectly soluble and contains 54 per cent. of metallic arsenic. It would be foreign to my purpose to enter into anything like an elaborate analysis of this valuable paper. I will content myself by stating that the learned authors have shown that the physiological action of a substance may be completely altered by introducing into it a definite chemical change without breaking up its molecule. Thus, by adding iodide of methyl to the non-saturated base, strychnia, its poisonous properties were greatly diminished. The authors conclude that while "physiological activity is related to condensation, the occurrence of saturated substances such as alcohol, corrosive sublimate, and oxalic acid, having a well-marked poisonous action, and of condensed substances such as benzoic acid and salicine, which are comparatively inert, shows that condensation is not the only condition of physiological activity. There can, at the same time, be little doubt, that if the effect of condensation were discovered and eliminated, the other conditions might be much more hopefully sought for."

While Crum Brown and Fraser were thus working in this country, Jolyet and Cahours were pursuing an almost identical line of investigation on the Continent. (d) Knowing that in various compounds an equivalent of hydrogen may be substituted by an organic radical without chemically changing the fundamental properties of the original compound, they investigated the question as to whether this substitution would modify the physiological properties of the compound. They compared the action of aniline with that of ethyl-aniline, trimethyl-aniline, and amyl-aniline. They found that while the

action of aniline is to excite the cerebro-spinal centres so as to produce convulsions, the action of the derivatives was to abolish the function of those centres. One of the most definite chemico-therapeutical laws has recently been enunciated by Rabuteau. It is to the effect that metals are more active physiologically according as their atomic weights are higher or as their specific heats are lower. This law holds good as regards the diatomic metalloids, but the monatomic metalloids are governed by a law which is the reverse of this. The metals rubidium, tungsten, and molybdenum form exceptions to this law. I should not pass over the fact that M. Rabuteau has proved that the organism is a reducing agent converting bromates into bromides, sulphates into sulphites and hyposulphites, and so forth.

B. Ward Richardson has done good service in drawing attention to the connection between chemical constitution and physiological action as evidenced by the alcohols. The number of atoms of carbon contained in an alcohol would seem to serve as an index to its activity; thus, ethylic alcohol contains but two atoms of carbon, while amyl alcohol, which is much more active, has five atoms.

I purpose now to direct your attention to certain axioms which that advanced therapist, M. Gubler, has recently advanced relative to the sphere of action and of elimination of drugs. (a) I say "axioms," for, for lack of absolute proof, we cannot assign to these propositions the standard of definite laws. The first of these axioms or theorems may thus be stated: Substances tend towards their similars or analogues in the animal economy—thus, sulphur would tend towards sulphur, phosphorus towards phosphorus, arsenic towards phosphorus, bromine towards chlorine, selenium towards sulphur and so on. A second theorem is that when a substance cannot meet with its similar or analogue it cannot be assimilated, and must be eliminated. A third proposition is that a substance is eliminated by that channel in which it meets with similar bodies—thus, neutral salts, sulphocyanide of potassium and soda, would be eliminated by the *saliva* and *pancreatic juice*; soda, fatty acids, neutral fatty bodies, cholesterol, resin, and ferruginous pigment by the *bile*; neutral salts, substances acting as acids, fatty matters, water, and ferruginous pigment by the *urine*; gas and vapours by the *breath*; casein, lactone volatile fatty acids, butter, and neutral salts by the *milk*; and fatty acids, volatile acids, and neutral salts by the *sweat*. For my own part I am inclined to regard these theorems as in the main verging on absolute truth, and until they are disproved, or until some equally intelligible and plausible proposition is offered, I will elect to regard these axioms of Gubler as adequately explanatory of the sphere of action and of the channel of elimination of drugs. I lean strongly to the opinion that the presence of quinioidine in animal tissues, as has been demonstrated by the masterly researches of Bence Jones and Dupré, is a powerful argument in favour of Gubler's views.

I will now briefly allude to a subject of considerable interest which M. Onimus has recently brought under the notice of the Académie des Sciences. That investigator finds that the interposition of a layer of some albuminoid substance, as the white of an egg, between two liquids, often gives rise to electro-chemical phenomena. If into an U-shaped tube some albumen be poured, and if into one side a solution of sulphate of copper be placed, and into the other side a solution of oxalate of potash, after a while blue crystals of double oxalate of copper and potash will be formed. Again, when phosphate of soda is placed in one side, and chloride of lime in the other, phosphate of lime will be obtained in the side in which the phosphate of soda was placed. These facts are not without therapeutical application, for we may infer that it would be more beneficial to administer these salts separately than to give phosphate of lime directly, since this salt is so easily formed in the organism.

The discovery of the physiological action of chloral by the illustrious Lieberich has given such an impetus to the study of the decomposition of chemical agents in the organism that it is probable this line of research will ere long extend to the whole course of therapeutical learning. The attention of the Académie des Sciences has lately been occupied by the extremely interesting researches of M. Byasson and M. Personne relative to the chemico-physiological action of chloral. In the "Monthly Reports on the Progress of Therapeutics," which I have the honour to edit for the *Edinburgh*

(a) "Proceedings of the Royal Society of London," vol. iv., Jan. 28th, 1841.

(b) "An Attempt to apply Chemical Principles in Explanation of the Action of Poisons." ("Proceedings of the Royal Society of London," vol. xvi., 1863.)

(c) "Transactions of the Royal Society of Edinburgh," vol. xcv.

(d) "On the Substitution Compounds of Aniline." (*Comptes Rendus*, tome lxxvi., 1 68, p. 1131.)

(a) See an article by M. Bordier in the *Bulletin de Thérapeutique*, January 30th, 1873.

*Medical Journal*, I have not omitted to refer to these investigations. M. Byasson thinks that the longer duration of the action of chloral compared with that of chloroform is due to the slowness of the chemical action, and that the difference in the physiological phenomena is explained by the intervention of formic acid produced at the same time as the chloroform and acting under special conditions. M. Personne, on the other hand, is of opinion that the combination of the chloral with albumen explains the longer duration of action of this body compared with chloroform. The first action of chloral on the albuminoid materials of the economy produces chloroform at the expense of their alkali; at the same time, these materials, deprived of their alkali, contract a combination with the undestroyed chloral, and this combination is, in some sort, a reservoir of chloroform. Thus is explained why it is we meet with so small a quantity of chloroform in the blood of animals submitted to the action of chloral. The theory that the action of chloral is in part to be accounted for on the supposition that formic acid is produced, and is subsequently reduced into carbonic acid in the system, M. Personne has endeavoured to disprove experimentally. He gave formic acid to dogs without perceiving the slightest production of carbonic acid, nor did any symptoms of anæsthesia supervene.

I have this evening briefly glanced at some important chemico-therapeutical researches which have recently occupied the attention of scientists. I trust on a future occasion to bring forward a more ample statement, and to formulate some additional laws which my own researches would seem to warrant, but the enunciation of which in their present stage would be premature.

It will be seen from what I have stated that I am an ardent disciple of the School of Chemical Therapeutics. I must be understood, however, to advocate as ardently physiological and clinical research. The labours of the chemist will be unavailing if not co-existent with the researches of the physiologist, and both must be supplemented by the careful observations of the clinical physician.

The flood of light which is being shed upon the nature of diseased action by the labours of the physiologist and pathologist, the modern refinements of clinical investigation, and the impetuous progress of chemical science will ere long bear fruit in the establishment of a therapeutic method worthy the name of science. Have not the researches which I have brought under your notice this evening an importance as evidencing a line of investigation pregnant with golden promises. May it not be that the generation to come will look back on the empiricism of to-day as do we on the pretensions of the past.

## INDIAN MEDICAL NOTES.—XXVIII.

MEERUT, September, 1874.

### YESTERDAY AND TO-DAY.

THERE'S nothing new under the sun. In the *Asiatic Journal* for 1828 runs a paper by Whitelaw Ainslie on "The Constitutions considered suited for India." Younger than 21, older than 36, were objectionable ages, excepting for lively cadets, heaven-born civilians, or grave governors, judges, or generals holding positions of comfort, without excessive exposure to extreme heat, or fatigue by day, nor to the noxious dews of the night. On the look-out for vivid colour, animated look, firm step, cheery voice, clear eye, clean tongue, inoffensive breath, or for middle-aged steady, sober, seasoned soldiers; no dull, fallow, bloated, pot-bellied recruit—perhaps epileptic, scrofulous, syphilitic, skin diseased, or idiotic—need apply. Dyspeptics were expected to dine on one dish, to take but two meals daily, at six hours' interval, to keep temperate, to walk or ride in moderation, avoiding chills or excessive fatigue.

In 1824, an inflammatory fever in Bengal, characterised by sore-throats, rheumatic pains, cutaneous eruptions, great prostration, spared neither age nor sex, the resident or the stranger, neither the natives nor the animals. Hot sultry months, irregular rains suddenly checked, had something in connection with this fever, which, specially severe in May, was treated by bleeding, purgatives, and emetics. During life the heart's action would be vio-

lently tumultuous, and after death the spleen enlarged, liver mottled, abdomen distended, and the skin yellow, were noticeable points. In June, 1828, broncho-pneumonia was very fatal to children under four years of age. When, in 1829, at Meerut, the rains, of eccentric frequency and unusual quantity, suddenly ceased, very early in September (a hot month, with chilly nights), the Europeans and natives generally were universally stricken with bilious remittent, the severe cases assuming the worse type of jungle fever, whilst milder forms passed off as simple intermittent. The oldest inhabitants suffered the most, the protracted debility, dejected aspect, despondent minds, all culminated through tardy convalescence in eventual recovery. The much-abused canals, blamed as the cause of typho-malarial fevers to-day, then did not flow near Meerut. In 1830, at Penang, when horses had glanders, human beings suffered from ardent fever, rheumatic pains, sore-throat, increased discharges from nose, ear, and eyes. In 1832, at Indore, when vaccination never failed, the people suffered from epidemic catarrh, which that year, in the month of April at Meerut, attacked 200 men of the 26th, without one single death, according to Dr. Playfair, who then wielded the medical thunderbolts here. In 1836 the Pali plague, traced to cloth-printers, and limited to towns in connection with the sick, terribly scourged certain places, names unknown, the buboes in groins, arm-pits, and neck non-suppurating. Ever so long ago the belief existed that malaria was the common parent of fever and cholera—a view adopted by Dr. Alexander Smith.

To-day there are but scanty materials to supply the possibly bewildered practitioner with the chronicles of the past; there are but few brightly-shining beacons to point the dangerous rocks, the hidden reefs, or cruel quicksands, and to pilot our course through friendly channels into the harbours of safety. Probably the laborious researches of Cunningham and Bryden, however, have not been studied by those who imagine that doctors have free command of power and purse, able to drain stations, build barracks, change climate and constitutions by the wave of the magic wand, just as the spangled fairy transforms the regions conducive to malaria into realms of perpetual bliss. Thanks to fevers, our hospitals just now are largely patronised, for instance, to-day, September 16th, when the flock have to be watched with anxious vigilance, to prevent simple cases in-idiotically drifting into dysentery, enteric fever, perhaps cholera. Before the days of thermometers, probably many a nian dragged about until fatal collapse, from perforation closing the scene, caused panic. Depend upon it, these fevers have a common malarial origin, or connection of cerebro-spinal character, requiring hypodermic treatment, the success influenced by early recognition, diagnostic skill, the patient's constitution, and, above all things, by the best of nursing from moment to moment.

In the commencement of enteric fever the treatment by cold baths or wet sheets may succeed; yet, if delayed until the green gangrenous ulcers have almost destroyed the ilium, the weak watery blood poisoned throughout, the poor heart bowed down by internal clots, the remedy should not entirely be blamed when perforation, collapse, hæmorrhage, erysipelas, Bright's disease, hæmaturia, purpura, pneumonic embolism, aortic aneurism, obstinate constipation, neuralgia, deafness, or a host of other consequences supervene. To-day my inclination is to praise the cold baths—who knows for how long? Indeed, the only remedies thoroughly believed in are quinine, mercury, and turpentine, the latter in iritis, puerperal fever, epilepsy, worms, hæmorrhages, or, for local application, something marvellous. In 1867 the east wind apparently blew cholera eighty miles from Morada—bad to Meerut—where, out of 155 cases, 22 survived—the Artillery and 19th Hussars very lightly stricken compared to the Buffs, whose tents were eventually pitched under the welcome shade of trees, for the flight from the Scylla of cholera may tend to the Charybdis of heat-apoplexy.

As usual, between August 17th and September 25th

vacated barracks, latrines, urinals were fumigated with nitrous acid; astrigent medicines, tea, coffee, charcoal-filters, cots, extra tents provided; fruit, vegetables, muddy beer interdicted; fatigue prevented, the infected clothes and bedding burnt. No cause could be discovered; the pebbles of inquiry thrown into the pond caused a few bubbles besides the splash and eddy for a while, then the rest was silence. The native troops and prisoners escaped; so they did in 1869, when Dr. Muir thinks a sick traveller by rail imported cholera, on the 15th of August, the day as dangerous as the Ides of March to Julius Cæsar, in the opinion of medical Zadkiels. Why did the traveller select that day? Irrespective of the city population, there are 25,000 people in one bazaar, the smell far more tolerable than the fried-fish aroma of Clare Market, where I spent a night professionally once, after dining right royally with a City company. Concerning the epidemic which mildly affected the 4th Hussars, Artillery, the 105th Regiment, Dr. Lewis, examining the soil microscopically in solution during the first few days, found no infusoria; afterwards they appeared in great numbers in the soil near the Hussar barracks, mostly consisting of phases in the existence of monas lens, altering their form very rapidly, frequently protruding an amœba-like vesicle. There were also amœbæ with filaments, multiplying by division. In 1872 the prisoners had a turn at Meerut, where, about the 14th, or more decidedly, the 21st of August, that cruel vapour—call it what you will, the question is an open one—permeated certain places, sparing the Rocket Troop Lines and other barracks with erratic caprice, cruelly scourging others, here and there insidiously smiting those susceptible, whether weakly or robust, especially the nervous, the curious concealer of disease, the man oppressed with anxiety, or the fool who doctors himself—sometimes one member of a family attacked, sometimes all; neither infancy nor old age, neither complexion, sex, temperament, rationality, pregnancy, nor acclimatisation conferred immunity. Those acclimatised who had not taken the curve down hill did not escape attack; yet several recovered, on the same principle as middle-aged practitioners become callous to virulent variola, scarlet or typhus fever, or erysipelas, which unconsciously they may convey to their patients or their families. Purgatives provoked attacks, apparently influenced by malaria, associated with fever—it was difficult to distinguish—for, simultaneous with cholera and fever appeared dengue, followed by acute dysentery, in fact, hardly a man was fit for duty; almost every officer was sick. The deaths in the district amounted to 510; and who can tell how long the excreta in the soil saturated with the products of former epidemics will remain susceptible to the influences of heat and moisture?—influences telling with tenfold intensity on those enfeebled by months of heat, constant rain, stagnant atmosphere, heavy clouds, with or without thunder, the wind easterly; all welcomed the sun's vengeance on the flat, undrained, spongy, possibly miasmatic soil. The 105th encamped at first two, then seven miles, from the barracks, until it pleased God to bid the destroying angel stay. There are heaps of books, diagrams, tables entering into the statistics of stages of collapse, reaction, married, single, barracks, all accessible in England to the interested, who, however, above all things, would like to know the treatment tried—sinapisms, turpentine, opium, effervescent, chloroform, camphor, strychnine—1-32nd of a grain in solution hypodermically, chloral, milk, beef-juice, sago, figured amongst the favourite weapons. In that practicable and valuable journal, the *Indian Medical Gazette*, there is a paper by Dr. Jessop, 4th Hussars, on "Irritant Causes of Disease," wherein he alludes to two cases of meningitis caused by blows on the head, both contracting dysentery in hospital, showing the connection between direct injury to the nervous centres and the integrity of the intestine. Also at Meerut, during the trouble of 1872, a man contracted dysentery by sitting over the same latrine as another affected. A firm believer in Dr. George

Johnson and castor-oil, Dr. Jessop, apparently a medical officer of "great and vast experience," as the saying is, swears by turpentine, combined with soda, gum, tinct. cardam. co., tinct. opii, and castor-oil, at the commencement of suspicious sickness. This very day two cases of dysentery are associated with tape-worm, inducing high fever; after death by enteric fever such complications are occasionally noticed. Also, out of eighteen natives (mostly females, two pregnant) who hung themselves, twelve had lumbrici in numbers in the small intestine, according to Dr. Goopta. Now, I ask any middle-aged well-to-do working general practitioner, is there any remedy at the commencement of any disease safer and better than a combination of opium, castor-oil, and turpentine?

## Hospital Reports.

### CASHEL UNION HOSPITAL.

(Cases under the care of Dr. LAFFAN.

By DR. W. P. HOURIGAN,

Medical Officer Tullaroan Dispensary, formerly Dresser to the Hospital, and subsequently Resident Medical Officer to Mater Misericordiarum Hospital.

A BRIEF abstract of some cases which were under Dr. Laffan's treatment from time to time may not prove uninteresting to your readers.

#### Grafting.

M. R., æt. 35, admitted for large indolent ulcer of the leg. The disease had existed off and on for some years, and at time of admission the sore had not healed for a period of eighteen months. All the treatment that ingenuity could suggest was in vain tried to procure the healing of the ulcer, and at length Dr. Laffan determined to give a trial to grafting. Accordingly he directed me to remove a portion of tissue from one of the arms. This was done, and having been cut into small pieces, was attached to the surface of the ulcer after the manner laid down by the late Mr. Woodman. The success of this treatment was remarkable; readily all the grafts took, the surface of the sore became dotted over with minute islands of granulations, and the ulcer, which had so long refused to advance beyond a certain point in obedience to any treatment healed perfectly in a few weeks.

#### Cut Throat.

A case of penetrating wound of the larynx may be usefully mentioned at a time when, thanks to the statistics of wounds in this region already published, surgeons have been enabled to form a more accurate estimate than hitherto of the intrinsic dangers of laryngeal wounds, and operations have in consequence been recommended and successfully carried out under circumstances where they would not have before been deemed admissible—such as, for instance, those performed by Langenbeck for the purpose of administering anaesthetics, and the practice of earlier operating in laryngeal and tracheal diseases.

The patient, a woman, æt. 40, came under Dr. Laffan's care for a self-inflicted wound, extending nearly from ear to ear, and involving the air passages in two places. One of the wounds penetrated the thyroid cartilage near the attachment of the thyro-epiglottic ligament; the other severed the thyro-hyoid membrane; the carotids had fortunately escaped. The patient, at the time she was seen, was in a syncopal state, pulseless, and blanched from the immense quantity of blood which had been lost. Measures to arrest the hæmorrhage and bring back animation were immediately resorted to, and the sides of the wound brought together by suture and position as directed by Mr. Erichsen. The centre of the wound, in accordance with the same authority, was left open and covered with folds of muslin. The patient was kept in a room heated to the temperature of 60°, and which was impregnated with

the vapour of steam, and she was watched day and night until all danger had ceased. Perfect recovery ensued after some weeks.

#### *Significance of Albuminuria.*

The existence, and still more the persistence of albuminous deposits in the urine is so uniformly associated in the mind of the practitioner with the gravest prognosis that it is comforting to know that not always does this persistence call for so much alarm.

A case of albuminuria, in a man *æt.* 50, was two years ago under treatment. Dr. Laffan had me make daily analysis of the urine for eighty consecutive days, and at the end of that time the albumen, which had persisted almost to the close, was found to have disappeared. Dr. Laffan has followed the after-history of this case, and within the last few days analysed this man's urine, with the result of finding it free from the least trace of albumen. There have been other cases also in which prolonged daily examinations of the urine have disclosed the same result; I may mention one notable instance: It occurred in a patient, *æt.* 60, suffering from severe dropsy depending on chronic bronchitis. Albumen was found in the urine, and continued for some weeks, and then disappeared. Remedies addressed to the dropsy subsequently removed that affection.

#### *Fracture of the Patella.*

This happened in a young man, *æt.* 25, and was caused by a direct blow. The knee-bone was completely fractured across. The case was seen within a few hours after the accident, when it was found that inflammation had already set in. Antiphlogistic measures were actively used, and as the fragments were being more and more separated, every hour an opportunity was anxiously looked for for putting up the fracture. This was deemed safe on the fifth day, and Hamilton's single inclined plane was employed. Twenty-four hours afterwards this had to be relaxed, and it was not until the eighth day that it could be permanently adjusted. The apparatus was maintained in position for six weeks, and when it was removed the fragments were found united by bone at one point and by a powerful fibrous band not exceeding two lines in length through the rest of their margins. Firm ankylosis was found also to exist. The after-history of this case has been followed up: the fibrous band has not become relaxed; all trace of ankylosis has disappeared; the joint is as strong as the other, and no lameness whatever exists. Speaking of this case, Dr. Laffan remarked that the earliest apposition of the fragments is of great importance in these fractures, as the longer they are left asunder the more they gape, and the less satisfactorily will they be brought together afterwards. The great difficulty is how safely to effect this in face of the inflammatory consequences which usually attend them.

#### *Fever Notelets.*

The admission of 402 cases of fever into the Cashel Fever Hospital within four years afforded me opportunities for noting a few points in treatment and symptomatology. Delirium, when it partook of the character of the tremens kind, was combated with most success by Grave's treatment. The cold douche, local depletion, and tartar emetic were found most suitable to cases of the sthenic variety. Capillary bronchitis was perhaps the most formidable of all the complications which occurred. Dr. Laffan found turpentine the most efficacious remedial agent for the relief of this. As regards the different kinds of fever, typhus was sometimes exclusively present, at other times typhoid prevailed; and again, fevers of the simple inflammatory type predominated. From time to time there were many cases which—making every allowance for the undoubted existence of defaced, irregular, and anomalous cases of fever—could not be classed under any hitherto described variety. Dr. Laffan remarked that there were still fields open to the careful clinical investigator, and that as typhoid had had its separate identity completely established only within a comparatively recent

period, so there were many grounds, supplied both by abstract reasoning and clinical experience, for believing that there are yet other varieties of fever to be discriminated, and from whose discrimination we may reasonably expect some additional light will be thrown on the essential nature of fever itself. Careful records of temperature were taken twice daily in the most important cases, but the readings did not always accord with the results laid down by the leading writers on medical thermometry. Some remarkable cases of defaced scarlatina occurred from time to time; in all the diagnosis was clearly established by the context, yet in some the only symptom was hæmic dyspnoea with albuminuria; in others swelling of the cervical glands, and in others again the presence of albuminuria only. In all these cases the diagnosis was aided either by a history of previous scarlatina propinquity, or by subsequent contamination of non-infected individuals.

#### *Epithelioma.*

A remarkable instance of the arrest of a formidable case of this disease came under notice. The disease appears to have been caused, or at least promoted by frequent attacks of throat catarrh, in a constitution broken down by the combined influences of an Indian climate, excessive mercurial salivation, and hardships of all kinds. The back part of the pharynx was alone involved at time of admission, but the affection soon engaged the soft and hard palates, completely destroying the former, and eating a large hole in the latter. The disease has now existed for a period of three years, and during that time three temporary arrests have occurred, the last extending over a period of eighteen months to present date. His present condition is that of a person in moderate health, able to work, sleep, and eat, and the local appearances are those of entire quiescence of the affection.

#### *Stricture of the Urethra.*

A case of organic stricture deserves a passing word. It occurred in a man, *æt.* 40, had existed for some years, and had three times produced complete retention of urine, this affection being present at time of admission. No.  $\frac{1}{2}$  silver catheter was passed with some difficulty, and the man's present symptoms relieved. Gradual dilatation was then employed, and the stricture enlarged up to No. 12. The point of interest in this case is that it turned out from the history that the man had been operated on previously by the forcible dilatation method, and it therefore furnishes us with another instance of the want of permanent success following such operative procedure; modesty in prognosis, therefore, is the obvious lesson. The man left after some time, with instructions from Dr. Laffan to have an instrument passed occasionally, as the only preventive against another recurrence of his complaint.

#### *Hydrocele (supposed) of the Neck.*

An instance of what was deemed to belong to this affection was operated on lately. It occupied the right posterior inferior cervical triangle, in a young female. Dr. Laffan tapped with the aspirator, and found it to contain purulent fluid. The puncture was then enlarged, and the tumour injected with iodine from time to time. Complete obliteration ensued.

#### *Cases of Entropion.*

Two additional instances of this disease were operated on within the last few weeks. In one Crampton's operation was performed. The other case was selected for the performance of Von Graefe's operation for spasmodic entropion. Both promise well.

#### *Fistula in Ano.*

A case of this disease, in a labourer, *æt.* 35, came under notice. It was of the blind external variety, had existed for six months, and had been previously subjected to a variety of treatment. The case was treated by pressure and injections for three weeks without result. Dr. Laffan then cut the fistula open, laying the two cavities into one. Rapid cure was the result.

## THE ACTION OF DRUGS.

## I.

At the present day a great deal of attention is being directed to the action of medicines, and new efforts are being made in all directions by various experimenters to obtain a reliable basis on which to found the treatment of disease. We may here call attention to the highly important researches of Professor Fraser, M. Sée, M. Choupe, M. Gubler, M. Dogiel, M. Byasson, Müller, and many other Continental experimenters. It is something to be grateful for that in this country similar awakening has occurred. We have only to mention the prolonged labours of the late Dr. Anstie, the well-known researches of Dr. John Harley on the vegetable neurotics, also Drs. Brunton, Dupré, Fothergill, and still more recently, the experiments of Messrs. Burness and Mayor on the horse and dog, the results of which are embodied in their work on the "Specific Action of Drugs;" and at the present moment the Report of the Committee of the British Medical Association appointed to investigate the antagonism of medicines is being published in instalments by the learned chairman, Professor Hughes Bennett. We must say that the devotion of the Association funds to such important researches is a redeeming point in the management of the Association, and worthy of all praise, and, considering the vast amount of labour bestowed on these investigations, the money devoted to it bears no proportion.

The Committee state that the object of the experiments was to ascertain by careful observation—

1. The physiological actions produced.
2. The minimum fatal dose.
3. The influence of one supposed antagonistic substance on the physiological action of the other when both were simultaneously injected.
4. The influence of the supposed antagonistic substance when introduced some time *before* the fatal one.
5. The influence of the supposed antagonistic substance when introduced some time *after* the fatal one.
6. The limits of the antagonism when such existed.
7. The performance in all cases of a crucial test consisting, when any supposed antagonistic action had saved the animal, in injecting the same dose of the active substance into the same animal a week or ten days afterwards. If death then took place, it was held that the two substances were antagonistic.

By such a method they hoped to ascertain, beyond the

possibility of doubt, whether one drug could really antagonise the fatal or injurious properties of another, choosing in the first instance, for experiment, such as exhibited the most powerful and unequivocal action. In this manner there have been investigated, during the four years over which the Committee's labours have extended, the antagonistic properties existing between—

1. Hydrate of chloral and strychnia.
2. Sulphate of atropia and Calabar bean.
3. Hydrate of chloral and Calabar bean.
4. Hydrochlorate and meconate of morphia and Calabar bean.
5. Sulphate of atropia and meconate of morphia.
6. Meconate of morphia and theine.
7. Meconate of morphia and caffeine.
8. Meconate of morphia and guaranine.
9. Meconate of morphia and infusion of tea.
10. Meconate of morphia and infusion of coffee.
11. Extract of Calabar bean and strychnia.
12. Hydrate of bromal and atropia.

We will now pass on to analyse the results obtained by the Committee, merely premising that the criticisms we make are offered in no carping spirit, but solely to set before our readers what we deem the true value of such experiments, and to note in how far they increase our knowledge of the action of drugs, and, while doing so, we hope to contribute our mite to the progress of therapeutics.

In the first place, it is evident that these experiments add to our knowledge of the physiological action of drugs, and thus may serve as guides to the therapeutic value of these drugs, and so may be made of immediate practical value in the treatment of disease.

Secondly, the other objects aimed at are also exceedingly useful; but we must express our regret that in the majority of cases rabbits were chosen as the subjects of experiments—as these animals are evidently particularly ill-suited for the purpose—a point to which we will call attention further on.

Twenty experiments were made on rabbits to ascertain the minimum fatal dose of hydrate of chloral, and the conclusion arrived at was, that twenty-one grains of this drug may be regarded approximately as the minimum fatal dose for a rabbit of 3 lbs. weight. Professor Bennett, moreover, adds that—

At the same time, it has been observed, both in this research and in others in which chloral hydrate was employed as a hypnotic, that not unfrequently a dose, which in the great majority of instances is not ordinarily fatal, may destroy life. This is a fact of considerable practical importance, and might be explained by the supposition that, in certain conditions of the blood or tissues, chloroform may be produced more rapidly than usual by the action, according to the theory of Liebreich, of alkaline salts in the blood on chloral hydrate. The effects produced by chloral hydrate are now so well known as not to require special description. The period of hyperæsthesia is well marked in the rabbit. Frequently a slight pinch will cause the animal to utter prolonged screams, which would not be so occasioned in the normal condition.

In connection with the above remarks, we may call attention to a recent article in the MEDICAL PRESS (July 29) by Dr. Burness, and also to page 81 of the work referred to above.

Next fourteen experiments with strychnia indicate that—The minimum fatal dose for rabbits of that drug is 1·96th of a grain for every 3 lbs. weight of animal, or 1·288th of a grain for every pound. Here also it must be

understood that the fatal dose is to a certain extent approximative; for in several instances animals died from a smaller dose, apparently from asphyxia produced by strong tetanic convulsions of the muscles of respiration.

Having thus determined the minimum fatal dose of the two substances, the action of both together was next investigated.

*Influence of Hydrate of Chloral on a Fatal Dose of Strychnia when both are given simultaneously.*

Professor Bennett concludes from twenty such experiments that chloral antagonises fatal doses of strychnia, and modifies the symptoms to a remarkable extent; while from eleven other experiments, in which the chloral was given after the strychnia, he concludes it is less efficient in counteracting the fatal effects of strychnia in proportion as it is administered at more distant intervals of time; while fifteen experiments in which the chloral was given some time previously to the strychnia, lead him to conclude that strychnia is not such a satisfactory antagonist to chloral as might have been expected. Professor Bennett adds that—

It was also observed that, in those cases in which the animals died notwithstanding the injection of strychnia, they died in profound coma, although, from the muscular twitchings and from the ease with which reflex spasms could be excited, it was evident that the strychnia was physiologically influencing the spinal cord. It would appear, therefore, that there is little hope of saving life after fatal doses of chloral hydrate by the subsequent injection of strychnia. Chloral hydrate acts, not only on the centres of the spinal cord, but also on the brain, as is evidenced by the profound coma following a large dose, and the injected condition of the membranes of the brain found after death. Strychnia, on the other hand, exercises no known influence on the brain; and, although it may stimulate the reflex centres of the cord, depressed in vital activity by the action of chloral hydrate, it cannot relieve the condition of the encephalon, and consequently, even though there may be muscular twitchings and even tetanic convulsions, the animal dies comatose.

Thirty similar experiments were made upon rats, from which similar conclusions were derived.

Professor Bennett thus sums up:—

It appears to be established from these experiments—

1. That, after a fatal dose of strychnia, life may be saved by bringing the animal under the influence of chloral hydrate.

2. That chloral hydrate is more likely to save life after a fatal dose of strychnia than strychnia is to save life after a fatal dose of chloral hydrate.

3. That, after a dose of strychnia producing severe tetanic convulsions, these convulsions may be much reduced, both in force and frequency, by the use of chloral hydrate, and consequently much suffering saved.

4. That the extent of physiological antagonism between the two substances is so far limited, that (1) a very large fatal dose of strychnia may kill before the chloral hydrate has had time to act; or (2) so large must the dose of chloral hydrate be to antagonise an excessive dose of strychnia, that there is danger of death from the effects of chloral hydrate.

5. Chloral hydrate mitigates the effects of a fatal dose of strychnia by depressing the excess of reflex activity excited by that substance, while strychnia may mitigate the effects of a fatal dose of chloral hydrate by rousing the activity of the spinal cord; but it does not appear capable of removing the coma produced by the action of chloral hydrate on the brain.

It is scarcely necessary to point out the vast importance of these results to practical medicine and the indications they afford, not only in cases of poisoning by strychnia,

but in cases of tetanus and other spasmodic diseases, reflex and central.

At a meeting of the Medico-Chirurgical Society of Edinburgh, on April 6th, 1870, and at the annual meeting of the Association at Newcastle in 1870, I demonstrated experimentally with what certainty rabbits might be saved after receiving a fatal dose of strychnia, by the injection of a solution of chloral hydrate. Take two rabbits of about 3 lbs. weight; inject under the skin of both 1.96th of a grain of strychnia, and then in one a solution of fifteen grains of chloral; in ten minutes the first one will leap into the air and fall down tetanic and dead; the other will go to sleep, and in about two hours will wake up as if nothing were the matter. A more certain antidote does not exist.

The results are what we might expect, when we bear in mind the physiological action of each drug, for if chloral be given first, we can quite comprehend that, by its action on the spinal cord, it may prevent the effects of the strychnia given afterwards; but given after a dose of strychnia, we can easily understand how limited is its power to prevent the poisonous actions of that drug, and, although we quite admit the force of Prof. Bennett's experiment before the Medico-Chirurgical Society of Edinburgh; yet, at the same time, we should hesitate before trusting to the same treatment in man, for we ought never to forget that the toxic effect of strychnia would be produced more rapidly on man than a rabbit, and with smaller quantities while it would be scarcely possible to bring the patient under the influence of chloral in sufficiently short time—in fact, would it not be preferable to give chloroform at once, and keep the patient under its influence until the poison be eliminated? And it must never be forgotten that, in almost all cases of accidental poisoning, the poison has been taken a considerable period before it is possible to administer any antidote. We can hardly accept chloral as a real *antidote* to strychnine.

Recently, Messrs. Burness and Major have published ("Specific Action of Drugs") experiments tending to show that morphia is an antidote to strychnia; and the MEDICAL PRESS of October 14 contains an article on this subject by Dr. Burness.

## HOMŒOPATHY AND THE MEDICAL PROFESSION.

THE entire medico-homœopathic press, comprising the *British Journal of Homœopathy*, and the *Monthly Homœopathic Review*, with the adventitious help of *Figaro*, whose trade it is to snarl, have combined in a violent attack on us in reference to the articles recently published by us on the subject of their speciality. We don't propose to enter at any length upon a reply to these articles, because they do not make any attempt at refutation of the theorem which we propounded. In reply to a public statement made by the President of the Homœopathic Congress to the effect that the homœopaths were subjected to persecution by medical men because they practised a particular theory of medicine, we wrote as follows:—

"The medical profession does *not* refuse to associate with homœopaths for any such reason, but, on the contrary, regards with the most perfect toleration the theory and practice of *similia similibus*. They regard it as unscientific and illusory, but they do not take upon themselves to say

that its practice is the result of anything else than a delusion. But they cannot say as much for the practice of infinitesimalism, which, the occasion obliges us to state plainly, they regard as a false pretence, the employment of which disentitles any person to associate with them.

"Medical men can imagine that homœopaths may honestly believe in the *similia similibus* theory, but they cannot be expected to conceive that the majority of the fraternity honestly believe in billionths, and they are therefore obliged to conclude either that homœopaths treat disease by effectual therapeutics under the pretence of giving infinitesimals, or that they pretend to treat disease by infinitesimals, well knowing that they are not treating it at all. This is the reason for the exclusion of homœopaths by the profession. It is for the public to say whether an injustice is thereby done to them."

This will be admitted to be a perfectly plain statement, which could be met only by proving that infinitesimalism is a *bonâ fide* scientific theory, which homœopaths can and do honestly believe and practise, and, therefore, that the medical profession act unjustly in refusing association with them in consequence of their adoption of it. We have not in either of the homœopathic journals found any attempt to prove this, but we rather find something like an admission that infinitesimalism is a part of homœopathy which its practitioners may or may not practise, although they still call themselves homœopaths (with the reservation, we presume, that they don't tell their patients their want of belief in that part of their theory).

"We have ever held," says the *British Journal of Homœopathy*, "that the principle *similia similibus* is the cardinal point, and not the infinitesimal dose. . . . We admit the utility of all other therapeutic methods experience has shown to be good, and hold ourselves free to make use of them when we think they will be advantageous for our patients. . . . We do not follow in a slavish manner the mode of applying the homœopathic law used by Hahnemann."

We want to know on what principle a disciple of Hahnemann who professes to believe that a billionth of a grain is necessarily and intrinsically the proper dose, feels himself justified in prescribing ten grains, which he *must* believe to be a highly injurious quantity? And we also want to know whether homœopaths who avail themselves of the option to oscillate between infinitesimalism and active dosage do tell their patients, when they choose to prescribe full doses, that in their particular case they have no faith in billionths, and mean to give full doses. We rather think not, and we rather imagine that their patient would—if they did so—probably refuse to take the allopathic dose, and set down as an arrant humbug a line of practice which thus halts between two opinions.

It seems to us that this defence of optional infinitesimalism makes the position of homœopaths worse than it was before. It is ridiculous to plead that infinitesimalism is a doctrine which a homœopath need not hold, and which, therefore, he may practise or not, as he sees fit. We assert that it is an essential tenet of homœopathy—in fact, in the public mind, it is the distinctive mark which divides homœopathy from scientific therapeutics, and without which (as far as patients can form an opinion) homœopaths would not differ very materially from allopaths. The pharmaceutical nomenclature of homœopathy, and the diction of every book on the subject, are our evidences of this fact; and yet the mouth-pieces of the

speciality maintain that "the infinitesimal dose is not a cardinal point," but that, on the contrary, homœopaths may set it aside when they like, and make use of "other therapeutic methods" whenever they find that infinitesimals are unavailing. What would be the verdict of Convocation as to the morality of a clergyman of the Church of England who subscribed to a declaration that the adoration of the Virgin and the temporal authority of the Pope among us were "damnable and heretical doctrines," and yet held himself at liberty to teach those doctrines to any one whose tastes or tenor of mind took that direction?

On this subject the *British Journal of Homœopathy* says:—

"As to the dose: before we ever heard of homœopathy some of the practitioners of that school were in the habit of giving doses only moderately below the strength required to elicit the physiological action of the drug; others pushed the dilution to what the first party deemed an extravagant length, and even held that the *very extreme of dilution was the corner-stone of homœopathy, and that to give medicines in the lower dilutions was allopathising*. As a matter of fact, we side with the former party, but we profess ourselves unable to draw the line where moderate dilution ends and extravagant infinitesimalism begins.

"But then the wisdom of the MEDICAL PRESS consists in knowing exactly the boundary between infinitesimalism and proper dosage; and, puffed up with this knowledge, it declares everybody a liar who humbly says he does not possess this knowledge and believes that it cannot be attained without scientific experiment."

It does not involve any great self-conceit to believe ourselves capable of drawing a line between infinitesimalism and physiological dosage. The intervening gulf is monstrous in its extent: on the one side lies physiology and scientific therapeutics, on the other a preposterous and inconceivable assumption—outrageous in its improbability, and incapable of any experimental proof. We don't pretend to fix a boundary where a medicine begins to exercise a physiological effect; but our common sense tells us that the lowest estimate of that limit must be vastly distant from the highest known boundary of honest infinitesimalism (if we can use the adjective)—so far removed, indeed, that it is an insult to that common sense to confuse the one with the other.

But, in fact, our charge against homœopaths is not so much that they practise what they do not profess, and profess what they do not practise, as that they acquire popularity with those who believe in their healing powers by pretending to a method of practice which they do not always carry out, and which they avow that they consider optional.

If they openly declared that experience had taught them the unwisdom and uselessness of Hahnemann's theory in certain cases, and that, in such cases, they would prescribe full doses, they would, in so far, be acting ingenuously. They do nothing of the sort: they say, expressly or impliedly, to their patients, "Come to us and be cured! We are the new light. No more nasty mixtures! No more of that terrible mercury that loosens your teeth and saturates you with health-destroying poison. Come to us, and we will cure you with nice little globules which *can* never do you any harm, and may be bought ready-made and taken by yourself, without the expense of the apothecary, or the fear of poison, and which are much more certain

to cure you than the drugs and drenches of the old-fashioned and obsolete allopaths!"

It is this cry which attracts nervous old ladies, weak-minded valetudinarians, and stingy old maids; and if the professors of homœopathy were once to declare that they sometimes gave globules, and sometimes gave medicine, and that sometimes infinitesimals were no use, the declaration would speedily bring the fabric of homœopathy to the ground and abridge the fee-income of its practitioners.

Once again we repeat that it is entirely untrue that homœopaths are put in Coventry for practising a theory of medicine which—however unscientific and unsupported—they may honestly believe in. They are refused association with the medical profession because it requires too much charity and too great credulity to suppose that they have honest confidence in the remainder of their theory.

We had almost forgotten the little snarl of our volatile contemporary *Figaro*. When an editor is paid to "do" leaders on little club scandals, bits of green-room gossip, and music-hall performances, it is expecting too much to imagine that he can write comprehensible truth about medical matters. Here is the expression of the editor's acquaintance with the history of medicine:—

"If a doctor discovers something new about the character of a disease, or an effective treatment, he is forthwith denounced as a quack. Most likely he will be professionally ruined; or, if he is fortunate enough to have a practice, in spite of his daring to be more clear-sighted than the rank and file, he is insulted, calumniated, and cold-shouldered by the profession."

Gentlemen who can "throw off" an *ore rotundo* statement of fact and opinion on any subject at a moment's notice have their value in a newspaper office; but it would be well if there were some one at hand to make sure that they do not incautiously publish a statement which is directly and obviously the reverse of fact, and the falsehood of which at once overturns the whole argument. The editor of *Figaro* is evidently the right man for homœopathic journalism, and we congratulate the Hahnemannists on having secured an advocate who is not restrained by ridiculous scruples as to truth or sense.

## A PURE WATER SUPPLY.

(Continued from page 380.)

It is because Mr. Homersham is well acquainted with the danger of drinking unwholesome water, and as thoroughly impressed with the necessity there is for directing public attention to the danger, that he treats the question of a pure water supply in no apathetic spirit. He wishes to rouse a Government pledged to a *sanitas sanitatum* policy to the great importance of a pure water supply for the people free from all the attendant risks of mercenary water companies. If the Government will but take up the subject in an earnest spirit, there will be at once an end to a lavish expenditure of money to secure the monopoly of a dirty water supply taken to Wakefield and Sheffield, or any other town in the kingdom. Mr. Hogg's report of various specimens of water taken from the Wakefield mains, and the Sheffield Waterworks Company's reservoir, the "Godfrey Dam," confirms in every particular the statements made by Mr. Homersham as to their organic impurities, which arises from the fact that a few large cities derive their supply from natural lakes; many others from rude artificial basins or lakes,

formed by placing an earthen embankment or dam across a suitable valley that serves to collect together and store the perennial stream, and the flood waters that, after great and sudden falls of rain, flow down the valleys from above. These dams form lakes when full that frequently cover from one to two hundred acres of land with water, shallow at the upper end of the valley, and from 80 to 100 feet deep lower down near the dam. Sometimes the lakes are full to overflowing, at other times nearly empty. The sides and bottoms of the lakes for the most part consist of the natural surface of the land; the mould, grass, trees, shrubs, and other vegetation growing on the ground that forms the inside being rarely or never removed, but merely covered with water. The area of the surface of uplands that drain into such lakes vary from one thousand to five or six thousand acres, and large portions of such areas are often covered with peat, heather, and grass, frequently well stocked with grouse and sheep. The flowing stream and the rapid floods necessarily carry with them the leaves, blossoms of trees and shrubs, the droppings of birds and animals, and portions of the peat and other impurities into the lakes; in this manner the bottom and sides get covered in many parts with organic matter that soon decays, and with offensive mud. Living organisms find a congenial habitat in the mud and in the water, and rapidly increase and multiply there, more especially in the warmer seasons of the year.

The languid dirty stream, "the Calder," whence the present supply of Wakefield is drawn, is as narrow as a canal as it passes the town. It not only receives the sewage of the district, but the waste products of numerous large manufactories located on its banks, the refuse from which at times imparts a deep brown colour to the water for miles. The Don is little better, as its waters are exposed to contaminating influences exceedingly prejudicial to health, as it courses along densely populated districts.

During warm weather and an increased temperature, both animal and vegetable organisms rapidly multiply in such waters, and as a considerable quantity of organic matter is held in solution, no filtration will render them wholesome, or convert them into good potable waters. The ova of minute animal and vegetable life invariably find their way through the best filtering beds. The paramœcium animalcules, it is well known, cause serious forms of illness, diarrhoea, &c. Even animals suffer from drinking water in which these animalcules abound; while some other larval forms of animals living in water have to pass through the stomach of the higher animals before they are known to affect human beings. The anguillula fluvialis, for instance, that infests the intestinal canal of fishes, is believed to originate the dreaded trichinina disease. The microscope has more recently detected the presence of infusorial animalcules (bacteria) in the blood of some hospital patients after operation, and of those who die from blood-poisoning. Minute vegetable fungoid bodies attack fish and often kill them; and cows and sheep, as well as fish, have been known to be poisoned by drinking water from a stream contaminated with putrescible vegetable matter, the refuse of a starch manufactory on its bank, and which no filtration would remove or separate.

"Water taken from the Godfrey Dam," says Mr. Hogg, "had a yellowish hue, and on standing half an hour a considerable deposit was thrown down. On placing some of this under the microscope, it was seen to consist of masses of organic matter, living animals, &c., as the well-known infusorial animalcules, entomostraca, daphnia pulex, some of which were visible to the naked eye, paramœcium, anguillula fluvialis, a species of eel-like worm, amoeba, &c., together with spores (protococcus pluvialis), portions of coniferæ, desmids, and numerous fragments of decaying vegetable matters, such as are usually found in river and pond waters, the normal temperature of which in summer is not much below 70° Fah."

Several other specimens drawn from the Wakefield mains and near the head of the river Don were of a brownish tinge, and on agitation the nose detected a faintish sewage odour; on standing, the amount of sediment was not

large, but this, on examination, proved to be organic matter. It consisted of the outer cases of entomostraca (water fleas) of a considerable size, infusorial animals, wheel animalcules, stentors, paramœcium, cercomonas, &c., vegetable matter, confervæ, diatoms, and decaying fragments of peat and moss.

In striking contrast to the Wakefield and Sheffield reservoir waters examined is a specimen procured from a deep source sunk in the red sandstone geological formation, the normal temperature of which is 48° Fahr.

"This water, on standing, remains clear and bright. It is perfectly free from organic matter of every kind. The microscope discovered only some minute mineral matters. It is fresh and agreeable to the taste, colourless to the eye, and pleasant to the touch—a moderately soft washing-water, and in every way suitable for dietetic and household purposes."

In concluding his report, Mr. Hogg observes:—

"There are one or two points that deserve particular attention. First, as to the tenacity of life of the lower forms of animals. Very many animalcules' eggs are but little affected by temperature; the ordinary heat employed in culinary operations does not always kill them, nor a long drought or intense frost destroy their vitality. Secondly, as to the relative hardness or softness of potable waters. These are terms which convey very little information as to their salubrity, for while no one has asserted that a moderate quantity of mineral matter, carbonate of lime, in water, is prejudicial to health, every medical man of experience will agree with me that living organisms, and even small quantities of putrescent organic matters, are extremely dangerous. There can scarcely be a second opinion that water so contaminated is insalubrious, and unfit for drinking and culinary purposes, and since this is unavoidably the condition of surface waters, we must all hope to see the time when our towns, ceasing to be supplied with the waters of rivers or lakes, will derive their drinking-water wholly from deep springs."

## Notes on Current Topics.

### University of Dublin.

At a meeting of the Provost and Senior Fellows of Trinity College, held on Saturday, 17th October, 1874, it was resolved:—

1. "That the Senior Lecturer, in conjunction with the Medical Registrar, be directed to recommend examiners to assist the Professors in the Medical School at the examinations in botany, physics, chemistry, and materia medica.

2. "That the Medical Registrar be directed to give every facility to the visitors of the General Medical Council for the inspection of examination papers and of the answers thereto, but not to resign the custody of these papers.

3. "That a three months' course of practical instruction in animal histology be added to the Curriculum for the degree of M.B., under the superintendence of the King's Professor of the Institutes of Medicine; and that the Bursar of Trinity College be authorised to expend a sum not exceeding £110 in the purchase of instruments for that purpose."

These three ordinances of the Board are especially interesting when read in connection with the views recently expressed by the Medical Council. The first of them is apparently framed with the intention of meeting the objection that, in the University, the majority of the

examiners have hitherto been the lecturers in the School of Physic, and that therefore the students of other schools, who had not the opportunity of acquainting themselves with the personal "tips" of the lecturer, must necessarily be at a disadvantage before the examiners. Henceforth, a candidate will have an equal chance of being tested by an extra-academic examiner in the subjects named in the ordinance; but we do not understand why the reduplication of examiners should be confined to these subjects and not extended also to anatomy, surgery, physiology, and medicine.

The second ordinance is an endorsement of the view taken by the Council of the College of Surgeons, and by this journal, that it is neither advisable nor just to the students that the visitors of examinations should be permitted to carry away the written papers of candidates and publish them, as was done in the last report, "with all their sins upon their head." The visitors have a right to expect nothing more than a fair and full opportunity of forming an opinion as to the appropriateness of the questions, and as to whether the marks given fairly represent the merits of the answers. These points can be as fully ascertained by an inspection by the visitors as by the examiners; and we hope that the Medical Council will see that this demand is untenable, and will not again make it the subject of resolutions.

The third ordinance is interesting, as indicating a change in the nature of the courses delivered under the name of "Institutes of Medicine." For many years, under the Professoriate of Dr. Law, the lectures dealt almost exclusively with pathological physiology and practice of medicine. Since Dr. Purser's appointment, the Professorship has been, to a certain extent, erected into a Chair of Practical Physiology, such as has been so ably developed by Dr. Burdon Sanderson and others. This ordinance is the first introduction of the subject into Irish medical schools, and it evidences the advanced tone of the teaching which is carried out under the supervision of the Board and Professor Haughton. The influence of that gentleman as Medical Registrar has always been in favour of the widest expansion of scientific and educational free trade in Trinity College. By degrees the Board is—at his suggestion—abolishing all restrictions which had been set up for the protection of the school, and it is gratifying to observe that this creditable and progressive policy has been attended with advantages to the School itself and to the University which the old system of restrictive protection never could have produced. *Macte Virtute!*

### Sanitation in Dublin.

THE Public Health Committee of the Dublin Corporation have had their meeting for appointment of officers under the Public Health Act, and have, as we predicted, done their best to combine the gratification of some neat jobbery with the desire to defeat the objects of the Act and the intentions of Parliament. The following are the appointments and salaries: James Boyle, Esq., C.E. Executive Officer, £300; Dr. Mapother, Consulting Medical Officer, £300; Dr. Cameron, Medical Officer and City Analyst, £300; thirteen physicians of the City Dispensary Districts at £10 each in addition to their present emoluments. Sanitary sub-officers and inspectors

of nuisances : Mr. Edwards, £26 ; Mr. Webb, £46 ; Mr. O'Connor, £52. There were also appointed as sanitary sub-officers the following police officers : Inspector Halligan, £160 ; Inspector Bury, £160 ; and three sergeants at £89 14s. each, one sergeant at £5 4s. nominal, two at £84 10s., two at £81 18s., five acting-sergeants at £2 12s. nominal, their salaries being paid by the Commissioners of Police. Clerk, £52 ; assistant to city analyst, £39 ; keeper of the disinfectant chamber, £39 ; and keeper of the Morgue, 15s. per week.

The only point which we think worthy of notice, is that the Committee have imposed upon the city the expense of an entirely unnecessary number of sanitary sub-officers, to do the work which is vested in the medical officers of health, or dispensary medical officers. The Legislature have considered the medical officers to be the proper persons to inspect and report to the Committee ; but the Committee will not be denied their inevitable job, and, while they declaim against the great expense of paying the medical officers proper salaries, they, at the same time, decide to give handsome incomes to policemen to do the same work. Truly, never was a community so burthened with an incompetent and unscrupulous administration as is the "second city in the Empire."

We understand that the dispensary medical officers have unanimously refused the proffered insult—we will not call it a salary.

#### The late Dr. Thomas Ballard.

A FEW of the private and professional friends of this much-respected practitioner have determined, in token of their friendship and esteem, to place a simple but fitting memorial of him over his grave. Dr. Barratt, of 8 Cleveland Gardens, Hyde Park, has kindly undertaken to act as treasurer.

#### Archives of Dermatology.

A NEW journal, under this title, appeared on the 1st of October, and will be issued quarterly. It is American in origin, and is intended to represent American dermatology, but every effort will be put forth to make its scope cosmopolitan by devoting nearly or about one-half of each issue to the digest of current literature. Each issue will consist of 96 octavo pages, with suitable illustrations as required, special attention being given to photographic work and microscopy.

#### Compulsory Removal of Infected Patients to Hospital.

THE town of Ballyraggett, in the county Kilkenny, has been the scene of an outbreak of typhus, and a question was thereupon put by the guardians to the Local Government Board respecting their authority to enforce the removal of an infected patient to hospital. The Local Government Board replied as follows :—

"Local Government Board, Oct. 17, 1874.

"SIR,—The Local Government Board acknowledge the receipt of minutes of the 12th inst., containing a resolution in which the guardians request to be informed as to the course they should adopt in regard to the cases of persons suffering from fever who refuse to be removed to hospital ; and in reference thereto, I am to state that the 26th section of the Sanitary Act, 1866, and the 54th section of the

Public Health Act, should be read together ; the former, in order that, on the certificate of the medical practitioner, the necessary order for the removal of a patient to an hospital within the sanitary district, may be issued, and the latter in order that, in the event of the order for removal being disobeyed the culpable party shall, on conviction of the offence, before the magistrates, be liable to a penalty not exceeding £10."

#### Medical Microscopical Society.

THIS Society held the first meeting of its second session at the Royal Westminster Ophthalmic Hospital, on Friday, the 16th ult. The number present sufficiently testified to the flourishing state of the Society. A paper on "A New Method of Micrometry," communicated by Mr. John Gorham, of Tonbridge, was read by the President, and there was a good exhibition of specimens and instruments.

#### Spurious Teas.

AT a recent meeting of the City Commissioners of Sewers it was stated that there were millions of pounds of spurious tea in the wharves and warehouses of the city of London, some of which had been accumulating for thirty or forty years. The attention of the sanitary authority having been directed to the fact, it is to be hoped they will not let it be distributed to the public.

#### The Treatment of Wounded in Time of War.

IT has been officially notified to Surgeon-Major Dr. Porter, Assistant Professor of Military Surgery in the Army Medical School, Netley, that he has gained the Empress of Germany's prize for the best essay "On the Treatment of Wounded in Time of War." Surgeon-Major Porter was one of the army medical officers selected to accompany the English Ambulance, under the auspices of the Red Cross Society, in the late Continental war.

#### In Memoriam.

A HANDSOME painted window has been placed in the chancel of Petworth parish church to the memory of the late Mr. William Morris, M.R.C.S., L.S.A., of that town. The subjects of the window are "Peter and John at the beautiful gate of the Temple," and "Peter raising Dorcas to life ;" and below it is a brass plate stating that the window is erected in memory of Mr. Morris by many of his patients and friends "as a witness of their esteem for him in his life and their sorrow at his death."

#### General Medical Council.

ON the 7th inst. a representative of the University of bridge is to be elected, Professor Humphrey's term of office having expired. As re-election seems popular in the Council, and a better representative cannot be found, we look for no change.

DR. H. B. DONKIN, late of St. Thomas's Hospital, has been elected Assistant-Physician to the Westminster Hospital.

THE Lowestoft port sanitary authorities have determined, on the advice of the Local Government Board, to bury at sea all who die on their cholera ship.

### The Vacant Coronership.

THE lamented death of Dr. Lankester leaves vacant the office of Coroner for Central Middlesex. Dr. Hardwicke is a candidate. He has for twelve years been Dr. Lankester's deputy, and displayed conspicuous ability. The manner in which Dr. Hardwicke conducted the inquiry into the late explosion at Regent's Park, elicited the approval of all capable of judging, and we hope the electors will promote so well tried a servant to the place occupied by Dr. Lankester.

### A Cruel Joke.

A SURGEON living in a colliery district near Thornley was recently made the subject of a very cruel joke, says the *Pall Mall Gazette*. Word was brought to him that a terrible accident had occurred at a colliery in the neighbourhood, and he was urged to lose no time in going there with instruments, splints, lint and bandages. He hurried off accordingly, most elaborately prepared, and, the news having spread, he was followed with no less haste by numbers of the villagers. An accident had really happened near the pit's mouth. In the high gale which did so much serious mischief a few days ago a travelling waxwork show which had been exhibited to the miners was blown over, and the surgeon found that the patients for whom he had run himself out of breath were life-like figures of Mary Ann Cotton, who had lost one of her arms; Tropmann, the French murderer, whose skull had been fractured; and several other inmates of the "chamber of horrors," who had broken legs or arms, or received injuries more or less serious. The surgeon's disappointment and disgust deserve heartfelt sympathy. On public as well as on private grounds, too, these unseemly jokes should be discouraged. It would be exceedingly convenient if, in colliery explosions and railway accidents, lay figures could be blown up or smashed in the place of the actual sufferers. As, however, science has not hitherto perfected any such system of vicarious sacrifice, very awkward consequences may ensue if practical jokers permit themselves to trifle too often with medical men, and thus lead them to stay away when they are really wanted.

### "Fever in London."

WITH a view to united and prompt action to stamp out the fever now prevalent in some parts of London, the Local Government Board have called upon the Metropolitan Asylums Board for returns as to epidemics, and they show that at the Homerton Fever Hospital there are now 111 cases of scarlet fever, 21 of typhus, 60 of enteric, and 9 of other diseases of a fever character—total, 201. At Stockwell, 73 cases of scarlet fever, 35 of enteric, 8 of typhus, and 3 of other forms. At Homerton the small-pox side has been called into requisition for fever, and the managers have other accommodation in preparation.

DR. PAYNE, of St. Thomas's Hospital, is a third candidate for the Downing Professorship of Medicine.

THE Western Infirmary, at Glasgow, has been formally opened, and 200 beds will at once be occupied.

ENTERIC FEVER prevails at Over Darwen, Lancashire, and also at Nottingham.

THE *London Gazette* announces that H.R.H. the Duke of Edinburgh has appointed Dr. Arthur Farre, F.R.S., to be Physician-Accoucheur to the Duchess of Edinburgh.

THE Charing Cross Hospital Medical Society, which ceased to exist in 1869, on account of the paucity of students, has been revived, under the Presidency of Mr. Hird, dean of the Medical School.

MR. DARWIN, Mr. Herbert Spencer, Mr. Matthew Arnold, the Marquis of Salisbury, and Dean Stanley are all talked of as candidates for the Rectorial Chair in the University of St. Andrews.

WE regret to announce a report which has reached us that Dr. Foott, J.P., was killed near Mallow on Friday, by the fall of a wall, which some workmen were taking down.

WE are pleased to hear that the stipend of the present Demonstrator of Anatomy in the University of Cambridge is to be increased from £150 per annum to £230 per annum out of the chest, the increase to begin from Michaelmas, 1874.

THE jury who sat upon the body of a woman who died in St. Bartholomew's Hospital from alleged hydrophobia gave their verdict on Friday last, that deceased came by her death accidentally, thereby inferring that hydrophobia was not the cause.

DR. STEPHENS, on behalf of the Local Government Board, last week conducted an investigation into the sanitary state of Barton-upon-Irwell. The usual defects were found, and water was so scarce that Dr. Stephens encountered a man going round selling it.

IN London last week 2,556 births and 1,293 deaths were registered. The births exceeded by 233, whereas the deaths were 197 below the average in the corresponding weeks of the last ten years. The annual death-rate, which in the previous week had been twenty-one, declined to twenty per thousand of population.

THE weekly return of metropolitan pauperism shows a total number receiving relief of 91,066, of whom 34,716 were in workhouses, and 56,350 out-door. Compared with the corresponding weeks in the years 1873, 1872, and 1871, these figures show a decrease of 7,233, 12,260, and 24,408 respectively.

THE epidemic of typhoid fever which has been raging in Lewes for some weeks is slightly abating. A great number of persons have been attacked. A house-to-house inspection is being made, disinfectants are freely distributed, and neither labour nor expense will be spared in endeavouring to stamp out the disease. The annual procession of bon-fire boys has been prohibited for

the 5th with the same object. Dr. Thorne Thorne, from the Local Government Board, has, during the past week, been endeavouring to trace the first cause; but up to the present time no satisfactory conclusion has been arrived at.

## Transactions of Societies.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, OCTOBER 13TH, 1874.

C. J. B. WILLIAMS, M.D., F.R.S., President, in the Chair.

ON THE PATHOLOGY AND TREATMENT OF CHOLERA BY THE SUBCUTANEOUS INJECTION OF CHLORAL HYDRATE.

By AUGUSTUS R. HALL, Surgeon, R.A.

(Communicated by Dr. GEORGE JOHNSON.)

SURGEON HALL said that the treatment of the collapse of cholera by the hypodermic injection of chloral hydrate, had been, so far, comparatively successful. The Government of India had published reports on the subject in their *Gazette* of February 14th, 1874. The personal experience of the writer showed that the diarrhoea was perfectly painless, and the vomiting unattended with nausea. The pulse was at first hard, and then small, before ceasing to be felt. Meanwhile, the heart contracted forcibly, showing there was no tendency to syncope. The cramps in the voluntary muscles caused the real pain in cholera. The voice was squeaky before it became sepulchral. There was suppression of urine. As a rule, there was no loss of consciousness. Great thirst was always present. The comparative rapidity with which persons who survived an attack generally regained their health, tended to prove that no very serious permanent changes had taken place, either in the blood or in the intestinal canal. When water and oxygen could get to the blood, it performed its functions properly, and the epithelium was not apparently thrown off from the intestines to any great extent during life. The symptoms of collapse could be explained, chiefly by the experiments of Brown-Séquard, by great irritation of the sympathetic nervous system. The morbid influence of cholera exercised, probably, a stimulating action on the vaso-motor centres, producing increased heart action, contraction of the muscular walls of all the arteries, and at first, augmented blood-pressure. Dr. Parkes had shown the frequency of copious micturition of limpid urine in the early stage. This might be intimately related, according to Traube, to high arterial pressure. The heart contracted forcibly, but could not dilate normally, its muscular walls being spasmodically affected. The excessive activity of the vaso-motor centres was so great that the inhibitory or dilating action of the vagus on the heart was not allowed to control it. The left heart got very little blood from the lungs on account of the contracted pulmonary arterioles not letting it pass, so it could only send that little into the arteries; hence the small pulse in the latter stage. The right heart could not pump the blood, forced into it by the gorged vena cava, into the lungs, and was therefore full, and found so after death. The gorged systemic veins apparently caused the blue colour of the face and skin. The peculiar choleraic voice was not due to want of air passing into and out of the lungs. It was presumed to be caused by the abnormal condition of the nerves which supply the larynx. The cramps might be caused by the cutting off of the blood supply to portions of the muscles by the contracted state of their arterioles. Dr. C. B. Radcliffe had stated that contraction of muscle is a temporary death. The vomiting was apparently caused by the irritated state of the nerves supplying the stomach. The evacuations from the bowels might be the result of transudation from the distended nervous radicles of the portal system. The vomiting and purging seemed to be of secondary importance. It was the vaso-motor centres that produced asphyxia by their action on the heart and lungs, and to these our whole attention should be directed. The urinary bladder was generally contracted "to the size of a walnut." Abortions frequently occurred in pregnant women, the fetus being often expelled alive, indicating spasmodic contraction of the uterus as the cause. The perfect consciousness of the patient during the attack made it probable that there was no tendency to real

syncope. It was presumed that there was spasm of all the arteries of the body, and that the cause of death was asphyxia. To overcome this, pure sedatives, which soothed the irritated nerve-centres, and so put a stop to spasms, were recommended. It was of no good to give medicines by the mouth, as they were generally rejected at once; they must, therefore, be introduced subcutaneously. Practically, the best agent was chloral hydrate, which was a powerful sedative without exerting any primary stimulating action. The strength of the solution should be one part of chloral in ten of water. Ten grains in one hundred minims of water would generally suffice, put under the skin of the arms or legs in four or five different places. If the solution were stronger than this, it would probably cause ulceration. The patient generally craved for cold water, and this might be given in any quantity; but no opium or stimulants was to be given during collapse. If reaction did not set in within half an hour, the injections might be repeated. The secondary fever was probably a condition allied to heat-apoplexy, in which there was relaxation of the arterial walls, the result of exhaustion. In this state, experience had shown that the administration of quinine, with stimulants and tonics, was the best treatment.

## Correspondence.

### POSSIBLE ARREST OF HYDROPHOBIA, OR WATERSHY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In some recent communications addressed to the medical journals, I endeavoured to show that, if hydrophobia, or watershy, as I think we ought to term it, were dealt with differently—differently, I mean, from the way in which it is commonly dealt with, we might perhaps receive more favourable results. Hitherto hydrophobia, or watershy, has proved invariably fatal. I showed that in cases of poisoning, in cases where certain vegetable and animal poisons were the toxic agents, if only we could keep the patient for a time alive, the poison wore itself out, or was eliminated. This has proved the case when snake-poison was treated with large doses of alcohol, or when diluted ammonia was injected into the veins. It is notably the case with typhus poison and lues venerea poison. In the case of curara, a vegetable poison, artificial respiration, the respiratory muscles being for the moment paralysed, sustains life and averts otherwise inevitable death. It is the same, *mutatis mutandis*, in chloral-poisoning. In animals poisoned by croton chloral, artificial respiration, observes Dr. Oscar Liebrich, restores the heart's action, and life may be saved. In hydrophobia, if only we can maintain the duration of life a little, the effects of the poison, I would urge, might wear themselves out, and the individual be preserved. In hydrophobia, as everyone knows, the affected person cannot drink. Three pounds of water always, and sometimes even four or five pounds, are demanded by the economy. Now, this fluid, I maintain, might be injected into the intestines, or into the veins; in this case the water should be tepid. The privation of water alone, the toxic action of the hydrophobic poison apart, must be fatal. If, now, the sufferer were placed under the influence of chloral—and I have shown with what immense relief chloral was injected into the veins in cases of tetanus—there would be no difficulty in supplying the economy with water whatever. The hydrophobic spasms would probably be allayed, and the sufferer would be provided with drink, or at least water, which, in the ordinary course of hydrophobia, he is entirely unable to swallow. I have described the relief which attended the venous injection of chloral in cases of lock-jaw, and I may now add asthma. Assistant-Surgeon Chunder Banerjee, as Surgeon-Major Baillie, of Bhaugulpore, relates, (a) injected three grains of chloral, dissolved in twenty minims of water, subcutaneously, into the back of the neck of a woman labouring under intense asthma. In ten minutes after, the spasm had entirely ceased, and easy natural respiration had taken its place. I am urgently desirous that such members of the profession as may hereafter have an opportunity of witnessing cases of hydrophobia should have immediate

(a) See *Indian Medical Gazette*, June 1, 87

recourse to subcutaneous injections of chloral: the patients would undoubtedly be more or less relieved, water could be introduced into the system, and possibly the disease itself subdued.

I am, Sir,

HENRY MACCORMAC, M.D.

Belfast, October 26th, 1874.

## Gleanings.

### Fungous Origin of Erysipelas.

DR. WLADIMIR LUKOMSKY publishes in *Virchow's Archiv.*, 60ten Bd., 3tes u. 4tes Heft, the results of certain researches on the origin and nature of the poison of erysipelas.

After some preliminary remarks on various modern views of the affection, Dr. L. gives notes of two series of cases, as well as of experiments made upon animals, &c.

His conclusions from the first series are as follows. The following facts, he says, are established:—

1. The conclusions of other authors are confirmed, that severe and rapidly-spreading phlegmonous inflammation of the subcutaneous connective tissue, in which the cutis also takes a decided part, may be developed by the hypodermic injection of fluids containing organic germs.

2. The micrococci multiply rapidly in the connective tissue, and spread principally through the serous canals and lymphatic vessels.

3. This inflammatory process may be brought about by a fluid containing organic germs which at the same time shows no signs of putridity, as, for instance, fluids taken from living individuals. It follows from this that the existence of organic germs cannot in any way be regarded as a criterion of putridity.

4. Putrid (dead) fluids which do not contain micrococci and bacteria are not in themselves sufficient to bring about anything more than a local inflammation, which has no disposition to spread further.

5. The contents of erysipelatous blebs free from organic germs cannot cause, where subcutaneously injected, any symptoms of disease.

From his second series of experiments Dr. Lukomsky draws the following conclusions:—

1. Putrefying materials containing organic forms being placed in contact with a wound immediately bring about severe local inflammation, which may also comprehend the surrounding skin. This wandering disease-process cannot be distinguished in its general symptoms from the so-called erysipelas occurring in human beings.

2. The micrococci and bacteria penetrate the connective tissue by means of the serous canals, and wander by these paths still further.

3. They are found especially in the peripheric portions of the localised inflammation, and more particularly just where the inflammatory process is making most rapid progress.

4. Erysipelas moves preferably in certain directions. When, for instance, the wound in these investigations on animals lies in the middle line of the back or in its immediate neighbourhood, the process spreads with equal rapidity on one side and on the other towards the abdomen, more slowly behind, and still more slowly forward.

### Epidermic Grafts from the Skin of the Rabbit.

*L'Abeille Médicale*, No. 17, August, 1874, contains an article on this subject extracted from the *Rev. Méd. de l'Est*. After stating the fact that animal grafts are practicable, and giving various synonyms for the term "graft," the writer gives the following precautions for conveniently performing transplantation:—

1. If the borders of the ulcer are thick and the surface suppurates abundantly, they can scarcely be expected to heal. It is necessary, therefore, to alter the condition of the sore. For some days alcoholic washings should be used, and the dressing should contain glycerine. Transplantation should not be resorted to until the surface of implantation is covered with firm granulations and even a little dry.

2. Preparation of the graft. A healthy rabbit should have a small portion of the skin of the back carefully shaved off at some point where the hair has been previously removed

with sulpho-sulphuret of calcium. The fragment removed should contain a portion of the dermis and epidermis alone.

3. The fresh fragment should be transported to a portion of the sore previously designated, and which should be prepared by a few small incisions with a bistoury.

4. The fragments of epidermis should be fixed in its place by small strips of oiled paper, the ends of which extending beyond the edge of the sore are fixed by means of collodion. The wound should then be covered with a piece of linen soaked in glycerin and fenestrated; over this a compress of charpie, also soaked in glycerin or glycerole of starch, and a bandage over the whole. Collodion may be used to aid in fixing the bandage. The importance of using every means to prevent the graft from slipping is easily understood.

5. If the wound is in good condition, and but little suppuration is taking place, the dressing need not be removed for forty-eight hours. If, on the contrary, a certain amount of pus continues to be formed in spite of the precautions taken, the dressing should be changed at the end of twenty-four hours. If the fragment becomes fixed, it is slowly transformed, the pigment disappears, the animal epidermis is gradually dissolved, and there remains a mucous surface which easily cicatrises.

The cicatrix thus obtained has remarkable vitality, and presents a much better appearance than cicatrices obtained by other means.

The writer concludes by remarking that there results from the facts stated the following:—

1. Transplantation of epidermis from the rabbit to man can be performed with success.

2. In order that cicatrisation shall take place, it is necessary that the graft shall be perfectly fixed. The operation then goes on from a centre of new tissue within the sore, which becomes a centre of cicatrisation.

As soon as the extraneous integument once becomes firmly fixed, its pigment disappears, its epidermis disappears, and its cicatrix is from that time part and parcel of the human tissues.

### Chloroform in Eclampsia Infantum.

C. F. KUNZE (*Allg. Med. Central Zeitung*, April 1, 1874, No. 26).

In by far the greater number of cases of convulsions, we are unable to detect the cause, and it is a well established fact that such convulsions can take place without important organic changes being present. The conditions causing the convulsions pass rapidly away, and it is not even necessary that there should be any cerebral congestion. In all probability, we have to deal with an abnormal irritability of the nervous system. As proof of this, we find no increased temperature of the head, no injection of the bulb of the eye, no vomiting; there is no constipation, and no inflammatory pulse.

The author reports the following case: M. R., 11 years old, stout built girl, had, in her fourth year, a sickness, in which she had an attack of eclampsia infantum. The attack lasted two or three hours, and ceased after the administration of a stimulating enema and cool applications to the head while in a warm bath. No bad effects were left behind.

January 16, 1874.—Without known cause, was found unconscious, with general convulsions. The author being called, ordered three leeches to forehead, enema of salt and water, and an ice bladder to the head, although he found neither increased temperature of the skin nor of the forehead, and the child had had a regular operation the day before. No errors of diet had been made, the abdomen was soft, and there was nowhere tenderness on pressure. The pulse was 120—130 in the minute, and not particularly hard. At his second visit, four hours later, the leeches had drawn, and there had been a dejection; the head was cool, and yet the convulsions had not ceased. As the child had become cyanotic, and the lips were blue, and the respiration very rapid, with tracheal râles, the present condition having lasted eight hours uninterruptedly, it was expected that death would soon ensue. An attempt was then made with chloroform dropped upon a handkerchief. The convulsions ceased after a few inhalations, but consciousness did not return. The handkerchief being removed, the convulsions returned after a few minutes, and the chloroform was re-applied with equally good result, though but for a short time. Being then applied for double the time, the convulsions stopped for a quarter of an hour. With the next return, the application was carried to full narcosis. The child then began to breathe more slowly, the pulse went down to 100,

the tracheal râles diminished, the blue lips became red, as well as the cheeks, and after half an hour the child opened its eyes and returned to consciousness. After that, there was no return of the convulsions. At the evening visit, the child was somewhat excited, but otherwise there was no disturbance of any kind. A solution of bromide of potassium (5.0 grammes ad 120.0 grammes water) was prescribed, and since (six days afterwards) there was no return of convulsions, and the child was apparently in complete health.

### HOSPITAL SATURDAY.

AT the very inception of the Hospital Saturday movement in London we counselled caution, and expressed our great apprehension that it would have the effect of conferring upon all the opulent artisan class of the metropolis the right to demand hospital attendance and medicine in consideration of their donation of a sum which is utterly insignificant when placed beside the weekly expenditure of the same class for liquor and tobacco. We are sorry to observe that the result has realised our worst expectations. In spite of the benevolent, though probably mistaken, efforts of Archbishop Manning and other gentlemen—in spite of the banners and processions and street stalls, and all the other adjuncts to the getting up of charity steam, which cost no less than £1,100, the artisans have not contributed one-tenth of a farthing per annum per man. This is the spectacle cut by that great class which is to revolutionise everything, and which numbers its hundreds of thousands, in the receipt of plentiful wages—this the contribution to charities founded and maintained specially for their benefit. A penny per week for twelve months would have yielded £100,000. And what do they give? We are ashamed to mention the sum—it is such a miserable attempt at liberality; and yet it entitles each artisan to button up his pocket, spend the doctor's fee on some article of luxury, and hie him as a subscriber to any charity in the metropolis. No matter! the wire-pullers have been advertised to their heart's content, and surely that is something for the money, even though they have been compelled to appeal to the wealthy to defray the expenses of the fund.

### SURGICAL SOCIETY OF IRELAND.

THE first election of the Council of this Society by the members was held on last Monday, and marks a new epoch in the life of the Society. Hitherto the Council has been self-elective, subject to the approval of the Council of the Royal College of Surgeons, the cost of reporting and other expenses incident to the meeting being borne by the College. Within recent years considerable dissatisfaction has existed amongst the members of the Society because the subjects and authorship of communications to be read at the meetings were not publicly notified, as is done in all other societies. That they should be so notified was last year agreed to by the Council, and our readers have had the advantage of that arrangement by the regular announcement of the papers to be brought forward at each meeting. In spite of this concession, the members have been still dissatisfied that the election of the Council has not been vested in them, and a resolution was carried at the last general meeting of the College to the effect that the exist-

ing system of election was unsatisfactory. In accordance with this resolution, the Council of the Society had several meetings, and eventually it was decided by the Council of the College, at the suggestion of the Society's Council, that the administrative body of the Society should be annually elected by ballot, and that all members of the Society being Fellows of the College of Physicians or of the College of Surgeons should be entitled to vote.

The first election took place last Monday at 4 p.m., when the following gentlemen were elected:—Messrs. Colles, Wharton, Minchin, Richardson, Macnamara, Porter, Corley, Stokes, Mapother, Morgan, Hamilton, Tufnell, Butcher, Stapleton, Croly, Bevan, Walsh, Hughes, Bennett, Irvine, and Charles Benson.

## Obituary.

### THE LATE DR. LANKESTER.

It is with deep regret that the profession will hear of the decease of the great medical coroner, Dr. Elwin Lankester, M.D., LL.D., F.R.S., who since 1862 has discharged the high public duties to which he was elected in a manner calculated to make the Coroner's Court more respected than prior to his work.

He was born April 23, 1814, and therefore has expired in the sixty-first year of his age. Well do we remember the event of his election, and well has he repaid his profession for the effort then made to secure it. Alas! that his genial smile no more shall greet us, and his able head direct the inquiries he so well knew how to preside over. If we say but little on this point to-day, we must add a catalogue of his works, to show that it was not as judge in his own court that he chiefly distinguished himself. His whole career was honourable. Having been educated at Woodbridge, he was apprenticed to a surgeon there; from 1834 to 1837 he studied at University College, and in 1838 he became a Member of the College of Surgeons and Licentiate of the Apothecaries' Society. In 1839, according to a contemporary record, he visited the Continent, and graduated at Heidelberg; in 1843 became lecturer on Materia and Botany at the St. George's School of Medicine; in 1844 Secretary to the Ray Society; and in 1845 was elected Fellow of the Royal Society. In 1850 he was appointed Professor of Natural History, New College, London; in 1851 received the degree of LL.D. from Amherst, U.S.; in 1853 became Lecturer on Anatomy and Physiology at Grosvenor Place School of Medicine; in 1858 Superintendent of the Food Collections at the South Kensington Museum; in 1859 President of the Microscopical Society; in 1862 Examiner in Botany to the Science and Art Department at South Kensington; and was elected Coroner for Central Middlesex in 1862. Dr. Lankester contributed to the *Naturalist*, "Annals of Natural History," to the *Pharmaceutical Journal*, the "Penny Cyclopædia," and "Reports of the British Association for the Advancement of Science." He wrote the "Natural History of Plants yielding Food," and "Memorials of John Ray," published in 1845; edited the "Correspondence of John Ray," in 1846; contributed the article "Rotifera" to the "Cyclopædia of Anatomy and Physiology," and a "Report on the Progress of Organic Chemistry" to the "Companion to the British Almanack" in 1847; and published a translation of Schleiden's "Principles of Scientific Botany" in 1849. Dr. Lankester, who contributed reviews of medical works and papers on Natural History to the *Athenæum*, became joint editor of the *Quarterly Journal of Microscopical Science* in 1853; has written "Botany" in Hughes's "Reading Lessons," and, by command of her Majesty, edited the "Natural History of Dee-side." He translated Kuchenmeister's

"Animal Parasites" in 1859; contributed, in conjunction with Dr. Letheby, the article on Sanitary Science to the "Encyclopædia Britannica" in 1859; published "Half-hours with the Microscope;" "Two Addresses to the Microscopical Society of London;" "A Guide to the Food Collection at South Kensington Museum;" "A Course of Lectures on Food," and "A Course of Lectures on the Uses of Animals;" and delivered lectures on natural history and its various branches at the Royal Institution; several courses on physiology and botany at the London Institution; and several courses on botany before the Royal Botanical Society of London. As Coroner for Middlesex he published seven "Annual Reports" in the "Proceedings of the Social Science Association;" and as Medical Officer of Health for St. James's, Westminster, published fourteen "Annual Reports." In 1866 he edited the *Journal of Social Science*, and published a small work entitled "Cholera, what it is and how to prevent it." In 1867 appeared "Good Food, what it is and how to get it;" in 1868, "Vegetable Physiology;" in 1869, a "School Manual of Health;" and in 1870, "What shall we Teach, or Physiology in Schools;" besides several articles in *Nature* on scientific subjects.

## Medical News.

**Royal College of Physicians of London.**—On Oct. 29th the following gentlemen were elected Fellows of this College:—Robinson, Frederick, M.D. St. And., 47 Claverton Terrace, S.W. Carter, Thomas Albert, M.D. Edin., Leamington. Robertson, William Tindal, M.D. Edin., Nottingham. Green, Thomas Henry, M.D. Lond., 74 Wimpole St. W.

The following were admitted Members on the same date:—Sawyer, James, M.D. London, Birmingham. Godson, Clement, M.D. Aberdeen 8 Upper Brook Street, W. Newman, Alfred Kingcome, M.B. Aberdeen, Guy's Hospital, S.E. Greenfield, William Smith, M.B. London 93 Wimpole St., W. Ewart, William, L.R.C.P., 20, Leicester Square, W. Mahomed, Frederick Henry Horatio Akbar, London Fever Hospital, N. Johnston, James, M.B. London, Birmingham.

**The Anstie Memorial Fund.**—The committee formed to promote a memorial to the late Dr. Anstie have issued the following circular: "The death of the late Dr. Anstie, which took place on the 12th of September, in the forty-first year of his age, was occasioned by blood-poisoning, received, probably, through an accidental wound in the course of a post-mortem examination, while he was engaged in investigating the nature and causes of an obscure disease which had destroyed the lives of some of the children in the Royal Victoria Patriotic Asylum, at Wandsworth. A few days later, on the 23rd of September, a meeting of some of his professional and private friends was held at the house of Dr. George Johnson, F.R.S., 11 Savile Row; and at this meeting it was resolved:—'That, considering the labours of the late Dr. Anstie for the promotion of science, and the circumstances of his untimely death, it is desirable that some permanent memorial of his career should be established.' In order to give effect to this resolution the nucleus of a committee was at once formed by the gentlemen present. . . . In accordance with a wish very generally expressed, the executive committee have decided to recommend that a small portion of the sum subscribed (about £20) shall be expended in the erection of a tablet or other memorial in some suitable place, and that the residue shall be deposited with trustees, to be by them applied to the education of the children, or to their advancement in life, in such a manner as circumstances may render expedient, and in accordance, as nearly as possible, with the wishes which their lamented father would have entertained for them. A proposition to this effect has been submitted to Mrs. Anstie, and has received her approval and acceptance. . . . Subscriptions may be paid to the credit of the Anstie Memorial Fund, at the bank of Sir S. Scott and Co., Cavendish Square; to the treasurer, J. S. Storr, Esq., 26 King Street, Covent Garden, W.C.; or to either of

the undersigned, to whom also any inquiries relating to the matter may be addressed.—R. Brudenell Carter, 69 Wimpole Street, W.; Wharton Hood, M.D., 65 Upper Berkeley Street, Portman Square, W., hon. secretaries.

## NOTICES TO CORRESPONDENTS.

**H. G. W.**—The licence does not entitle the holder to style himself "Dr." It authorises him to practise medicine.

**BOLDO.**—Several correspondents wish to know what houses keep the tincture. Perhaps any house that may receive a supply soon will advise us.

**MR. J. B., HOLLOWAY, Peckham,** is thanked for his offer; but inasmuch as we have the official statistics ourselves—if we had only room to publish them—without copying from the *Sanitary Record*, we must decline the luxury of paying him five guineas for what we don't want.

**SCARCE NUMBERS.**—The Publisher will be glad to purchase clean copies of January 14th and June 3rd, *MEDICAL PRESS AND CIRCULAR* of this year, or to supply any others in lieu thereof, on application to the London office, King William Street, Strand.

**P. D.**—The 7th Edition of MacNamara's "Medicines" is the latest, and it is the best extant work on the subject. Roscoe and Cleland are also first-rate handbooks, and none better can be studied by a candidate.

**THE JACKSONIAN PRIZE ESSAY.**—The subject for the 1875 competitions to be awarded by the Council of the Royal College of Surgeons of England is, "The Use of the Galvano-Cautic in the Removal of Morbid Growths."

**CORONER.**—There are already four candidates in the field for the coronership vacant by the death of Dr. Lankester—viz., Dr. Hardwicke, deputy coroner; Mr. C. E. Lewis, M.P. for Londonderry; Mr. J. Mortimer Granville, M.R.C.S., for some years editor of the *Globe* newspaper; and Mr. James Boulton, a solicitor of Clerkenwell.

**THE PULSE.**—We are always glad to welcome any work which has for its object the enlightenment of the masses in those essentials about which so much ignorance prevails; and as beacons in the literature for the millions which must have a counteracting influence on the trash which weekly teems from the press, we know of no better or of healthier tone than such works as the *Leisure Hour* and *Cassell's Popular Educator*. Here is the common-sense way in which the functions of the pulse are taught in the latter journal for November: "The jerking motion of the blood, which it is the purpose of the elastic properties of the arteries to control, but which is not entirely subdued until the blood reaches the capillaries, causes that pulsation which is felt at the wrist, or at any other spot where the artery is sufficiently superficial, and which is commonly known as the pulse. The pulse is, of course, a measure of the frequency of the heart's action, as its beats correspond with the contraction of the ventricles; the pulse varies according to age, and is affected by many circumstances—the average in an adult is from 70 to 75 per minute; in an infant at birth, 140; whilst in old age it gradually declines from the adult standard; in persons of an excitable or sanguine temperament it is quicker than in the phlegmatic, and it is also more rapid in women than in men. After a meal the pulse is quicker than while fasting, and any exertion not carried sufficiently far to produce exhaustion increases its rapidity in proportion to the severity of the exercise taken. In the morning it is more rapid than at night, when the body is fatigued. Position also influences it; it is slowest in the recumbent posture; sitting or standing increases it, the latter more so, as requiring more muscular action."

**ITINERANT DOCTORING.**—Do you approve of the conduct of a medical man, enjoying a free railway-pass (through having charge of the company's officials for a certain district), availing himself of that privilege to visit other districts along the line upon office therein on all market days, and by underselling the local practitioners, endeavour to secure some business? To me such conduct seems unprofessional, and closely analogous to that of those migratory traders who, with cart and table, occasionally visit our markets, vending their nostrums to the poor dupes of ignorant credulity.—C. E. E.

[We decidedly disapprove of migratory doctoring, which is none the better because the free railway-pass granted for the care of the company's servants is made use of for the furtherance of private practice. As suggested by our correspondent, it is unquestionably unprofessional and undignified.—Ed. M. P. & C.]

**DR. M'C., Mitchelstown.**—Too late for this week.

**COMMUNICATIONS,** with Enclosures, &c., have been received from R. Letheby, London. Dr. Tilt, London. Dr. Hughlings Jackson, London. Dr. Alexander Burnes, London. Dr. E. Williams, Colchester. Dr. Pedro de Velasco, Madrid. Dr. McCall Anderson, Glasgow. Dr. Bathurst Woodman, Finsbury. The Hon. Secs. to the

Anstie Memorial Fund. Dr. Kiernan, Buckfastleigh. Dr. Lombard, Leamington. Dr. Boyd Mushet, Birkenhead. Dr. Kirby, London. Dr. Black, Glasgow. Dr. Dudgeon, London. Mr. Whatford, Brighton. Dr. Ormeby, Dublin. Dr. Routh, London. Dr. Drysdale, London. Dr. Williams, London. Dr. McGriger Croft, St. John's Wood. Mr. Squire, London. Mr. King, London. Mr. Haviland, Northampton. Dr. Hyslop, Church Streeton. Dr. Long Fox, Bristol. Dr. Beach, Cheltenham. Dr. Handzel Griffiths, Dublin. Dr. Bartle, Liverpool. Mr. Lunn, Edgbaston. Our Indian Correspondent. Mr. J. Robertson, Royal College of Surgeons of Edinburgh. Mr. Deprimé, Highbury. Mr. Wilde, Huddersfield. Mr. Fox, Manchester. Mr. Savory, London. Dr. Morgan, Dublin. Mr. Stansfeld, Bristol. Mr. Ingram, London. Dr. Langley, London. Mr. Holloway, Peckham. Mr. McClean, Norwood. Dr. Hayden, Dublin. Mr. Ward, Horn-castle. The Secretary to the Lord-Lieutenant, Dublin Castle. Mr. T. Moron, London. Mr. Nightengate, Folkestone. Mr. Jabez Hogg, London. The Registrar, Royal College of Physicians of London. Dr. Macnaughton Jones, Cork. Dr. Sidney Chater, Boulogne-sur-Mer.

## VACANCIES.

District Lunatic Asylums, Ireland. Resident Superintendent of the Castlebar Lunatic Asylum. Applicants must forward their testimonials, &c., to the Under-Secretary, Dublin Castle. (See Advt.)

Parish of Lambeth. Medical Officer for the Infirmary. Salary, £300 per annum, with extras. Applications, with testimonials, must be sent to the Clerk of the Union, at the Board-room Offices.

Queen's Hospital, Birmingham. Resident Secretary and General Superintendent. Salary, £150, with board and lodging. Address the Chairman of the House of Committee.

Jersey General Dispensary. Resident Visiting and Dispensing Medical Officer. Salary, £120 per annum. Apply to the Rev. P. Le Feuvre, Jersey.

Central London Ophthalmic Hospital. Assistant Surgeon. Honorary. North Wales Lunatic Asylum. Medical Superintendent. Salary commencing at £350, with house. Full particulars of Mr. J. Robinson, Denbigh.

Hastings Infirmary. Assistant Surgeon. Particulars of the Secretary. York County Hospital. House Surgeon. Salary, £100 per annum, with board and lodging. Address the Secretary.

Towcester Union. Medical Officer. Salary, £60 per annum, exclusive of fees. Applications to the Clerk of the Guardians.

## APPOINTMENTS.

ADRIEN, J. W., L.K.Q.C.P.I., Superintendent Medical Officer of Health for the Drogheda Rural Sanitary District.

ANDERSON, M.C., M.D., Physician to the Western Infirmary, Glasgow. ANDERSON, T. M.D., Surgeon to the York Eye and Ear Institution.

BENNETT, C. J., M.R.C.S.E., a Medical Officer of Health for the Truro Rural Sanitary District.

CARLETON, W., M.B., Superintendent Medical Officer of Health for the Delvin Rural Sanitary District.

COATES, S., M.B., Superintendent Medical Officer of Health for the Portumna Rural Sanitary District.

CROWT, J. D., M.D., Superintendent Medical Officer of Health for the Queenstown Urban Sanitary District.

DE RENZY, T., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer, &c., for the Arthursdown Sub-district of the New Ross Union, co. Wexford.

DONALDSON, Dr., Sanitary Officer for the Castleshaw District of the Monaghan Rural Sanitary District.

FRAZER, H., L.K.Q.C.P.I., Superintendent Medical Officer of Health for the Armagh Rural Sanitary District.

GAIDNER, W. T., M.D., Physician to the Western Infirmary, Glasgow. IRWIN, Dr., Sanitary Officer for the Scotstown District of the Monaghan Rural Sanitary District.

KELLY, J. D., L.R.C.P.Ed., Superintendent Medical Officer of Health for the Ballinrobe Rural Sanitary District.

MAHON, C. J., L.K.Q.C.P.I., Superintendent Medical Officer of Health for the Dromore West Rural Sanitary District.

MOORE, M., L.K.Q.C.P.I., Superintendent Medical Officer of Health for the Cavan Rural Sanitary District.

NELSON, E. F., M.D., Superintendent Medical Officer of Health for the Downpatrick Rural Sanitary District.

POWELL, E., M.D., Superintendent Medical Officer of Health for the Sligo Rural Sanitary District.

REED, Dr., Sanitary Officer for the Kilmore District of the Monaghan Rural Sanitary District.

ROGEE, J. M.D., Superintendent Medical Officer of Health for the Fermoy Urban Sanitary District.

ROSE, W., F.R.C.S., Surgeon to the Westminster General Dispensary. SEYMOUR, F., M.R.C.S.E., L.S.A., Assistant Medical Officer to the Norfolk County Asylum near Norwich.

ARMY MEDICAL DEPARTMENT.—Surgeon-Major J. Leitch, M.D., and Surgeon D. H. E. Anderson, M.D., retire on temporary half-pay; Surgeon-Major W. Ferguson, from half-pay, to be Surgeon-Major, vice F. A. McDermott, retired on temporary half-pay; Surgeon A. E. Bartlett to be Surgeon-Major, vice G. A. Hutton, retired on temporary half-pay.

## Marriage.

TRAUF—TOBIN.—On the 23rd ult., at St. George's, Hanover Square, Robt. W. Trauf, M.B., Surgeon 42nd Highlanders (The Black Watch), to Marjaret Anne, only daughter of the late Lieut.-Col. Tobin, 11th Regt.

## Deaths.

SMITH.—On the 23rd October, at Poplar House, Barnsley, George Smith, M.D., aged 74.

SHELL.—On the 26th October, at his residence, 50 Stepney Green, London, Edmund Shell, L.R.C.P.Ed., M.R.C.S.Lond., aged 53.

WOOD.—On the 23rd October, at Cookham-Dean, Maidenhead, Abraham Wood, F.R.C.S.E. (Hon.), formerly of Rochdale, in his 79th year.

**MEDICAL GENTLEMEN REQUIRED AS PROVINCIAL DIRECTORS** for a high-class undertaking. Remuneration, £500 each the first year. No liability.—Address BANKERS, care of Messrs. Imray and Daulton, 47 St. Mary Axe, London, E.C.

**DISTRICT LUNATIC ASYLUMS, IRELAND.**—The Office of RESIDENT MEDICAL SUPERINTENDENT of the District Lunatic Asylum at Castlebar being now vacant by the transfer of the Resident Medical Superintendent of that Institution to the Ennisworthy District Lunatic Asylum, candidates for that office are requested to forward their testimonials, with a statement of their peculiar qualifications for the appointment, to the Under-Secretary, Dublin Castle, on or before the 21st NOVEMBER next, in order that the same may be submitted to His Grace the Lord Lieutenant.

Applicants must be duly qualified to practise both in Medicine and Surgery, and registered as such under the Medical Act of 1859.

Candidates over 40 years of age are ineligible.

The Candidate who may be selected for the Office in question will have to enter upon his duties forthwith.

Dublin Castle, 31st October, 1874.

**DUBLIN INFIRMARY for DISEASES of the EYE and EAR, Ely Place.**

Ophthalmic and Aural Surgeon: ARCHIBALD HAMILTON JACOB, M.D. Dub., F.R.C.S., Ex-Ophthalmic and Aural Surgeon to the City of Dublin Hospital.

Consulting Physician: EVORY KENNEDY, M.D. (Hon. Caus.) T.C.D. and Edin., Fellow and Ex-President King and Queen's College of Physicians.

Consulting Surgeon: GEORGE H. PORTER, F.R.C.S.I.; M.Ch. T.C.D. (Hon. Caus.), Surgeon in Ordinary to Her Majesty the Queen in Ireland; Fellow and Ex-President, R.C.S.I.; Senior Surgeon to the Meath Hospital.

Obstetric Physician: JOHN CRONIN, M.D., F.R.C.S., Examiner in Midwifery, Roy. Col. Surgeons; Ex-Assistant Physician Rotunda Hospital.

Work, Income, and Expenditure for Twelve Months, ending June 30, 1873.

Annual number of Dispensary patients	...	...	...	5,847
Number of visits paid by such patients	...	...	...	124
Number of patients within the Infirmary	...	...	...	163
Number of operations performed	...	...	...	£37 15 0
Total gross expenditure per bed per annum	...	...	...	1 10 6
Average expenditure per intern patient	...	...	...	

The Infirmary is wholly dependent on private benefactions, and is in debt to the Medical Officer. SUBSCRIPTIONS ARE EARNESTLY REQUESTED

**CITY OF DUBLIN HOSPITAL, UPPER BAGGOT STREET.**

Physicians: HAWTREY BENSON, M.B. Univ. Dub., F.K. & Q.C.P.I., L.R.C.S.I. J. MAGEE FINNY, M.B. Dub., F.K.Q.C.P.I., Demonstrator Trinity College.

Surgeons: JOLLIFFE T. TUFNELL, F.R.C.S.I., Ex-Régius Professor of Military Surgery, and President Royal College of Surgeons. HENRY GRAY CROLY, F.R.C.S.I., L.K. & Q.C.P.I., Senior Demonstrator of Anatomy, Royal College of Surgeons. WILLIAM I. WHEELER, F.R.C.S.I., M.D. Univ. Dub., L.K. & Q.C.P.I., Demonstrator of Anatomy, Royal College of Surgeons. ARTHUR BARKER, L.R.C.S.I., Demonstrator Royal College of Surgeons.

Ophthalmic and Aural Surgeon: LOFTIE STONEY, M.D., F.R.C.S., Demonstrator of Anatomy. Consulting Physicians: Professor APJOHN, T.C.D., and CHARLES BENSON, M.D., Ex-Professor of Practice of Medicine, Royal College of Surgeons.

Consulting Surgeon: WILLIAM HARGRAVE, M.D., F.R.C.S.I., Ex-Professor of Surgery, Royal College of Surgeons.

Consulting Ophthalmic Surgeon: ARTHUR JACOB, M.D., Hon. T.C.D., F.R.C.S.I., Ex-Professor of Anatomy and Physiology, Royal College of Surgeons.

The WINTER SESSION commences in OCTOBER. The SUMMER SESSION commences in MAY.

Special Wards, under the care of Dr. LOFTIE STONEY, are appropriated for the reception of Ophthalmic and Aural cases, and a distinct course of Lectures on Diseases of the Eye and Ear (including Operations) is delivered, for which a Certificate is given.

There is a ward exclusively for Children, affording ample opportunities of studying the Diseases of early life.

Connected with the Hospital is an extensive daily Dispensary, at which the Pupils are allowed to perform the minor operations, and are rendered familiar with the details of Dispensary Management and the Art of Prescribing.

The "Purser Studentship," of £20 per annum (with apartment-), founded by William A. Purser, Esq., L.R.C.S.I., a former Pupil of the Hospital, is open to all Students through the medium of Competitive Examination, for which a special Certificate is given, if merited, and numerous Medals and Prizes are awarded in Medicine, Surgery, and Ophthalmology.

The Drummond wing, for Fever and other Contagious Diseases, affords full opportunity for studying these branches of Medicine. Instruction in Practical Pharmacy is given in the Compounding Department. Fee for Total Hospital Attendance, Twenty Guineas; Nine Months, Eight Guineas; Six Months, Six Guineas; Summer Three Months, Three Guineas.

For further particulars apply to Dr. WHEELER, Hon. Sec., 56 Pembroke Road, between Three and Four o'clock, or at the Hospital between Ten and Eleven o'clock a.m.

**THE STEWART INSTITUTION FOR IMBECILES,  
AND LUNATIC ASYLUM, LUCAN.**

PATRON:—H.R.H. THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life vote. Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office.

40 MOLESWORTH STREET, DUBLIN.  
W. O'NEILL, Secretary.

**MALVERN COLLEGE.**

This COLLEGE contains TWO DEPARTMENTS—the CLASSICAL and the MODERN. There is also a Preparatory LOWER SCHOOL. There are Boarding Houses within the College Grounds, held by the Head Master and others of his Staff; a Gymnasium, &c.

Board and Tuition under 14, £80; over 14, £90. Non-shareholders pay an extra fee of £6. Special advantages for Sons of Clergymen and Home Boarders.

For further information apply to the Rev. ARTHUR FABER, M.A., Head Master, late Fellow and Tutor of New College, Oxford.

The Examination for Scholarships and Exhibitions on December 22nd and 23rd.

**MEDAL**

1873,

VIENNA.

**MEDAL**

1872,

MOSCOW.

**MEDALS**

at Nine  
Exhibitions.

"Which really consists of pure Cocoa Nibs deprived of the superfluous oil."  
FOOD, WATER, AND AIR, Edited by Dr. HASSALL.

**FRY'S  
EXTRACT OF COCOA**

A perfectly pure and delicious beverage, prepared exclusively from choice Cocoa Nibs, deprived of the superfluous oil, and of great value to invalids who wish to avoid rich articles of diet. Purchasers of this class of Cocoa should ask for "Fry's Extract of Cocoa."

**LABELS CUT BY MACHINERY.**

**DISPENSING OR CHEMICAL STOCK LABELS,**

1s. 8d. per 1,000.

Ditto, with Name and Address, from 2s. per 1,000.

Mixture, Pill Labels, &c.

Labels printed to any pattern at equally moderate prices.

J. CROSS AND SON, Engravers, Steam Machine Printers, Lithographers and Stationers, 18 Holborn-Hill, E.C.—Established 1813.

**BUTLER'S MEDICAL HALL,**

53 & 54 LOWER SACKVILLE STREET,  
DUBLIN.

ESTABLISHED A.D. 1817,

or Compounding Prescriptions and Supplying Genuine Medicines, is conducted, as formerly, under the careful superintendence of

WILLIAM STARKEY, M.D.,  
Licentiate Apothecary.

**MR. I. SANDHEIM,**

Dentist,

18 STJFFOLK STREET,

DUBLIN.

N.B.—A Vacancy for a Pupil.

Established 1848.

**PROFESSIONAL AGENCY AND MEDICAL  
TRANSFER OFFICE.**

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.,  
&c. (King's Coll.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

**PRACTICES AND PARTNERSHIPS NOW OPEN**  
for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

Z 50. Near a large town, AN INCREASING PRACTICE, yielding upwards of £450 a year, with great scope for an active gentleman. There is a convenient house, with good garden, &c. Rent, £35. Patients middle-class. Terms, one year's purchase, half to be paid down.

Z 51. Within forty miles of London, with direct railway communication, AN OLD-ESTABLISHED PRACTICE, yielding £600 a year. Appointments, £40. The whole connection lies within a narrow compass. Patients good middle-class, and very few bad debts. Introduction as long as desired upon partnership conditions. The house has recently been put into complete repair, is small, but convenient, and in an excellent situation. Premium for a short introduction, a year's purchase, half of which may be left on security.

Z 52. WEST of ENGLAND. In a pleasant, well-populated district, near the South Coast, AN EASILY-WORKED PRACTICE, yielding £400 a year. No qualified opposition within four miles. All expenses are very low. The house is large, with garden, stabling, &c. Rent, £20. The vendor retires in consequence of an accident.

Z 48. In a pleasant town in the Midland District, a PRACTICE for TRANSFER upon easy terms, the vendor having accepted a Partnership elsewhere. The actual receipts have averaged about £650 a year, and there is great scope for extension, as the practice has not been actively pushed. The connection has been in the present hands about eight years, and is believed to be wholly transferable to a suitable gentleman. There are about 100 cases of midwifery in the year, chiefly at £1 1s. and upwards. The patients are middle-class. A small premium would be accepted from a doubly-qualified man of experience.

Z 46. EXCELLENT NUCLEUS in a northern town in a picturesque district. A doubly-qualified gentleman of Catholic opinions would be sure of success. £250 would purchase everything as it stands.

Z 42. In a thriving agricultural district, a WELL-ESTABLISHED TRANSFERABLE PRACTICE, yielding in actual receipts £1,100 a year. Advancing age the sole cause for retirement. Books open to the fullest investigation, and the highest references given. Appointments, worked with little trouble, produce £62 a year. The residence has been for many years associated with the Practice; it contains ten rooms, with detached surgery and consulting-rooms, stabling, and large garden. Rent, £42.

AUSTRALIAN APPOINTMENTS.—Dr. Langley is authorised, under guarantees from newly-settled districts of South Australia, to send out suitable doubly-qualified gentlemen forthwith. Personal application necessary. Appointments in Western Australia also vacant.

MEDICAL ASSISTANTS.—Gentlemen with good references, qualified and unqualified, can obtain immediate employment on application to Dr. Langley as above. No registration fees.

### ON THE SCIENTIFIC AND EMPIRICAL INVESTIGATION OF EPILEPSIES.

By J. HUGHLINGS JACKSON, M.D., F.R.C.P.,  
Physician to the Hospital for the Epileptic and Paralysed, and to the London Hospital.

#### CHAPTER II. (*continued*). DEFINITION.

PERHAPS the reader will miss one important set of symptoms from the list of Epilepsies given.

Epileptic Mania is usually, or often, spoken of as if it were owing to an *epileptic* discharge. An attack of mania is said to "replace" an attack of epilepsy. In agreement with this opinion I used to speak of short paroxysms of mania occurring in a person who at other times had convulsions as "epilepsies." I used to suppose that they directly resulted from such discharges as those which produce other paroxysms—convulsive paroxysms, for example—which I call epilepsies. I have for some years thought otherwise. There are discharges in epileptic mania, and they are abnormal, and they are of the organ of mind, but they are not epileptic (that is, not sudden, abrupt, and excessive) discharges.

I have several reasons for change of opinion. There is in most cases of epileptic mania clear evidence that the mania occurs when the epileptic discharge is over—that is to say, that the maniacal action is post-epileptic rather than epileptic. There are, however, cases in which there is no sign of an epileptic discharge (*i.e.*, no outward sign) before the maniacal action begins, as in cases of so-called masked epilepsy. I do not, however, adopt the accepted explanation of these cases—that they "replace" an epileptic fit. I think the evidence is in favour of another hypothesis—*viz.*, of a slight and unobserved fit. Let us consider, first, the cases of epileptic mania—I mean cases in which a prior fit is observed.

Epileptic mania occurs in those epilepsies where loss of consciousness is either the first, or nearly the

first, thing in the paroxysm; when there is "a warning," it is of a very general character. This is equivalent to saying that it occurs in those cases where the discharge begins in the very highest nervous processes. But it is found when the epileptic discharge is over, and the paroxysm has ceased. To explain the condition after the paroxysm, let us take a simpler case. Let us take a case where the discharge begins in a lower series of nervous processes—for example, in the corpus striatum, or rather in its adjacent convolutions. There is convulsion of the face, arm, and leg of the opposite side of the body, and possibly, if the discharge be excessive, universal convulsion. But after the discharge is over, there is, if the discharge has been unusually excessive, hemiplegia. This is, I consider, a sign to us that the corpus striatum has been put *hors de combat* by the violent discharge. We venture from these cases on the generalisation that "*Strong Epileptic Discharges Paralyse the Nervous Centre (or much of it) in which they Begin or through which they Spread.*"

Now we return to the cases where the discharge begins in the highest series, and apply the generalisation to them. There is loss of use of that series after a discharge beginning in it, when that discharge has been excessive. But obviously violent action (maniacal raving) could not result from this loss of use (a *paralytic* condition) of the highest centres. That accounts only for loss of consciousness (the highest centres which are now paralysed being the anatomical substrata of consciousness). That is only the patient's negative condition, and his condition is duplex. There is the positive element—the mania—to be accounted for. My opinion is that the mania is the result of over-action (morbidly increased discharge, but not epileptic discharge) of the processes just below those which have been put *hors de combat*. The patient is reduced to a more automatic condition of mind, or, as we have otherwise put it (Chapter I., Pt. 2, p. 350), his "adjustment is lowered." But why increased action of the lower processes? To lose consciousness is to lose control over the lower processes. This is a metaphorical expression. The physiological equivalent is to be given.

There is, after section of the spinal cord, increased reflex

excitability of the segments below the injury. Now, of this Bernard says (*"Leçons de Pathologie Expérimentale,"* 1872, p. 205)—I draw especial attention to the words italicised—"Nous trouvons, dans ce phénomène, un fait pathologique qui mérite d'être sérieusement étudié, *d'autant plus qu'il est applicable au système nerveux dans toute son étendue.* Tout nerf séparé du centre dont il émane acquiert des propriétés spéciales, qui ne diffèrent cependant de celles dont il jouit à l'état normal que par un excès d'intensité."

The principle that we get over-action of lower centres from the mere removal of the higher centres has very important applications. It was distinctly formulated by the late Dr. Anstie some years ago. Thus, speaking of the effects of opium, he wrote: "The apparent exaltation of certain faculties should be ascribed rather to the removal of controlling influences than to the positive stimulation of the faculties themselves, or of the physical machinery by which they work" (*"Stimulants and Narcotics,"* p. 80).

Let us state another reason why the symptoms of mania cannot be produced by an epileptic discharge (I mean, of course, produced directly by that discharge; they are, I think, as just stated, produced by it in a very indirect way). If the reader bears in mind what was said of the differences betwixt healthy and epileptic discharges, he will see that an epileptic discharge (i.e., a sudden and violent discharge) could not produce even that caricature of healthy action which is displayed in the doings of the epileptic maniac. This will be very plain if we take cases of elaborate mental automatism after very slight epileptic discharges. Thus, a man subject to epileptic attacks is found unconscious in the kitchen, mixing cocoa in a dirty gallipot (intended for the cat's food) with a mustard spoon. This was a very elaborate action, and that it was only a caricature of a normal action is plain, because it had just before been agreed on that his sister-in-law, who was on a visit, should have cocoa for her supper. It is impossible to believe that the cerebral discharges which produced such actions as the cocoa-mixing were like those discharges which produced convulsion. This patient was known to be the subject of slight attacks (*petit mal*) and severe attacks (*grand mal*). I believe that before the cocoa-mixing affair he had a slight attack of *petit mal*—i.e., a slight discharge beginning in his very highest processes, which had left some of them *hors de combat*. Then, so to speak, "under this loss" (which, symptomatically, was loss of consciousness) automatic action went on. That action was, in this case, only a slight caricature of normal action. But after stronger discharges, there is a deeper involvement of nervous processes (a deeper Dissolution), and correspondingly a lower kind of automatic action—e.g., maniacal raving, &c. After very strong discharges there is coma, a condition lower than mania, for by the discharges which produce coma all processes serving in mind seem to be put *hors de combat*, and there is only left the lowest "physical" automatic action (respiratory, circulatory, &c.). But neither the mental automatism of mania nor the physical automatism in coma can reasonably be attributed to the direct effects of an epileptic discharge.

What I have just been saying is in principle simply the obverse of what was said when speaking (page 391) of discharges of an hypothetical centre for visual ideas. It was pointed out that an epileptic discharge of those parts of the brain which are slightly discharged when we think of objects (or from somewhat increased discharge of which spectral images result) would not rouse ideas, but would cause simply clouds of colour and spasm of ocular muscles. The same principles apply to epileptic mania. An epileptic discharge could not produce actions so elaborate as maniacal action.

To recapitulate. In Epilepsy there is, as in healthy operations, both so-called mental and physical, a nervous discharge. But the epileptic discharge is a very local discharge; it is a discharge of some highly unstable part of the cerebral ( $\alpha$ ) hemisphere; it is an abrupt and ex-

cessive discharge. This definition embodies the principle of the new method. It amounts to saying that the phenomena of epileptic paroxysms are considered as developments, although in a brutal way, of the functions of limited parts of the brain. Returning to an arbitrary example. Strong lateral deviation of the eyes and clouds of colour are supposed to be developments in a brutal way of the motor and sensory elements in the anatomical substrata of visual ideas. It is for this reason that I call the method Anatomical and Physiological. As I shall show at length later on, I have for some years considered different varieties of convulsions as results of experiments in anatomy and physiology revealing to us, although in the rough the movements and impressions represented in different parts of the cerebral hemisphere; or, as I would otherwise put it, the localisation of the anatomical substrata of different classes of ideas, visual, tactual, &c. (See page 391.)

Obviously the method differs both as a means of Investigation and as a basis for Classification from the accepted method. Premising that chronic cases are spoken of, the accepted method starts by establishing some clinical entity (grouping of symptoms)—Epilepsy. And the question in a case is often only—"Does it satisfy the definition?" and not also—"How do the symptoms show a departure from health of some part of the nervous system?" The accepted definition of epilepsy is definition by type. The essential element in the accepted definition is loss of, or trouble of Consciousness, and this, for example, holds together the several varieties of epilepsy, vertigo, *petit mal*, and *grand mal*. It is sometimes said if there is no loss or defect of consciousness there is no epilepsy.

This absolute distinction into cases with, and cases without loss or trouble of consciousness, seems to me to be from a scientific point of view arbitrary. (a) It is an absolute distinction, not of anatomical or physiological, but of psychological parentage. Although it involves great recapitulation, I must consider the matter again in this place.

Loss of consciousness is not a symptom utterly different from other symptoms. It is not to be dismissed from analysis as a mysterious epiphenomenon or complication. Consciousness is mysterious, but *loss* of consciousness in cases of disease is to be considered on the same method as other nervous symptoms. Nor will it do merely to speak of consciousness as a "a function" of the cerebral hemisphere. Of course, in a sense it is so; but the expression is a vague one. For it is not a function in the same way as secretion of bile is a function of the liver. Physiologically the function of the cerebral hemisphere is, like that of the lower centres, to co-ordinate impressions and movements, or rather to re-co-ordinate those impressions co-ordinated by lower centres. Consciousness has, of course, anatomical substrata, as much as speech or any other mental operation has. These substrata are sensori-motor processes. How that other so-called function consciousness arises during energising of these substrata is not our direct concern. Similarly we must not simply speak of *loss* of consciousness as being due to "loss of function of the cerebral hemisphere." It is true enough in a sense, but in that sense it is almost a barren truism. We have to consider in an inquiry like this the nature of the anatomical substrata which are implicated when consciousness ceases.

The sensori-motor processes concerned in consciousness are only in great degree different from those of lower centres. They are the most special of all special nervous processes—the series evolved out of all other (lower) series. *To lose consciousness is to lose the use of the most*

convulsion with which there is loss of consciousness at or about the onset (cases of "idiopathic epilepsy" according to the accepted definition) depends on discharge of parts in *one* cerebral hemisphere. The reasons for this will be given later.

(a) In the next chapter I shall point out that Clinical Entities are necessary for practical purposes

(a) I wish particularly to mention now that I think *universal*

*special of all nervous processes whatsoever.* Now, one of the many ways in which the use of them may be lost is by their being the seat of an epileptic discharge. It will be temporarily lost *during their discharge* (during their excessive excitation) as much as it is permanently lost when they are implicated by gross lesion. It is just as the use of an arm is lost during the severe spasm of its muscles as much as by palsy of its muscles.<sup>(a)</sup> So then, whether consciousness be lost or not in an epilepsy, as I define it, or whether it be lost first of all or later in the paroxysm, depends on the seat of the discharging lesion, and on how far the discharge spreads. If those parts of the brain, where the most special of all nervous processes lie, be *first* affected by the epileptic discharge, there is loss of consciousness first of all. If the discharge be slight there may be, as appears, loss of consciousness only. This is so in very slight cases of *petit mal*. If strong, the discharge spreads from these very highest centres to lower centres, out of which these highest centres are evolved, and with which they are, therefore, continuous. The discharge widens as it spreads lower, and rapidly reaches the lowest centres and their muscles. There is loss of consciousness followed by convulsion. The accepted view makes the convulsion and the loss of consciousness to be two utterly different things depending on implication of two widely separate parts (medulla oblongata and cerebral hemisphere). This view, I believe, is partly owing to a psychological bias which, asserting that the brain is the organ of consciousness, finds it inconsistent with that assertion to speak of it also as an organ representing impressions and movements. On the view I take, discharges beginning in and spreading from the very highest centres (since they re-represent all that lower centres represent) will produce loss of consciousness, convulsion, and such symptoms as pallor of the face, passing urine in the fit, &c.

The view I have put forward will necessarily seem strange to those who are thinking of "Consciousness and Convulsion." They will see no possible relation betwixt the two things. Consciousness and Convulsion are utterly different things. But then I am thinking only of loss of use of the *anatomical substrata* of consciousness. It is the excessive discharge of these (during which consciousness ceases) which is comparable with that discharge of lower centres which produces convulsion. The things to be compared are discharges of sensorimotor processes of different series. So far from comparing consciousness with convulsion, I should not compare it with anything whatever, except perhaps metaphorically. It is the metaphysico-materialistic method, erroneously called "practical," which leads to such comparisons and explanations.

So far for epilepsies in which discharges begin in the highest centres. If the epileptic discharge begins in a subordinate series of nervous processes—in a lower centre—loss of consciousness does not occur, or occurs later. It only occurs when the discharge spreads far. Let us take an example. In some cases of discharge of convulsions near to the corpus striatum, the convulsion begins in the hand, and if the discharge be severe it spreads gradually over the whole body. The inference is: that there is internally a corresponding spreading of the discharge in the brain. In such cases consciousness is in most (b) cases not lost until, or just before, the leg on the side of the body first affected is reached by the spasm—that is, not until the central discharge

has spread widely in the brain. Consciousness may be lost in such a case from one of two causes. It is lost either as soon as the most special of all processes are reached by the internal discharge which began in the subordinate series; Secondly, consciousness must be lost when a large quantity of a subordinate and yet important series of nervous processes is suddenly involved in the discharge.

The last remark is important. Let us state very generally what it involves. If a patient *suddenly* loses by any process the use of *any large part* of either of the two cerebral hemispheres he must lose consciousness. For since the highest processes are evolved out of, and are, as it were, *continuous with*, processes only in degree lower, and through these with still lower unto the lowest, they have no independent existence. Consciousness must be lost when any important although subordinate series is seriously involved.

Here it may be well to remark expressly that, although medical men speak *clinically* of loss of consciousness as if there were a well-defined entity called consciousness, there is probably not amongst educated persons any such belief. We must for Clinical purposes have arbitrary standards (definitions by type). It is thus the universal custom for medical men to speak of "confusion," "stupor," "loss of consciousness," and "coma," although every medical man sees cases in which there are all conceivable degrees from slightest confusion of thought to deepest coma. Let me mention some slight degrees. Some patients will tell that in their fits they are not unconscious, but that they do not know where they are; that they hear people talking, but do not know what they say. It is not at all uncommon for the patient to say that when in a fit he feels as if in a strange place—"in a strange country," one of my epileptic patients said.

It would be as absurd to judge of a medical man's opinions as to consciousness by the terms he uses for describing the states of his patients as it would be to judge of a botanist's opinion on biology by considering only the terms he used in speaking of plants in his kitchen garden. It must be admitted that the two-fold use, the empirical and scientific, of terms leads to apparent contradiction in some of our medical phrases. Thus it is said "the patient was confused but was quite conscious." To be confused is to have defect of consciousness. Again, loss of consciousness is sometimes spoken of as being synonymous with coma.

It is clear, from what I have already said under Evolution, Chap. I, Part 2, p. 349, that no abrupt limitation of consciousness is recognised in this book. Thus I have used the term "defect of consciousness" when speaking of Insanity. To use the words of Herbert Spencer, (a) "all gradations exist between wholly unconscious nervous actions and wholly conscious ones."

In an anatomico-physiological inquiry what we have to note is how the organism is adjusted to its environment. Thus we should say that the patient whose case was mentioned (p. 410) was only very slightly less specially adjusted to his environment than was normal to him. He went through "the form" of the cocoa-mixing, used implements of the right class, but not those exactly fitted for the purpose. In the case of the headless frog which rubs vinegar off its back with a hind leg, there is a degree of adjustment very like normal adjustment. Whether con-

(a) We have also spoken of loss of consciousness as an after-effect of a strong discharge being due to exhaustion of a nervous tract consequent on excessive stimulation. This is so of the convulsed arm; its use is often lost after the discharge as well as by being involved in spasm during the discharge.

(b) Much depends on the rapidity of the discharge. I mean, for example, that consciousness is lost the sooner the more rapidly the spasm "runs up" the arm. If the spasm spreads slowly it may involve the whole of one side of the body without being attended by loss or even defect of consciousness.

(a) The following extract is of great interest in this connexion: "It does not follow, as it at first seems to do, that feelings are never located in the inferior nervous centres. On the contrary, it may well be that in *lower* types the *homologues of these inferior centres* are the seats of consciousness. The true implication is, that in *any case* the seat of consciousness is that nervous centre to which the *most heterogeneous impressions* are brought; and it is not improbable that, in the course of nerve evolution, centres that were once the highest are *supplanted* by others in which *co-ordination is carried a stage further*, and which thereupon become the places of feeling, while the centres before predominant become automatic." (Spencer, "Psychology," vol. i., ch. vi., p. 105. No italics in original).

consciousness is displayed or not in such adjustments is not a physiological, but a psychological question.

Mr. G. H. Lewes believes that Sensibility is a histologic property; this is, he believes, a fundamental property of the ganglionic tissue. We ought, according to him, to consider the sensorium as having the same extension as the nervous centres. This view is not necessarily discrepant with the statement I have made about the anatomical substrata of consciousness (that they represent the whole organism). Mr. Lewes has made a remark which is at least parallel to that statement. He defines the common sensorium ("Physiology of Common Life," vol. ii.) as "*the sum of all the lower centres, each centre being itself a small sensorium.*"

In the next chapter I shall show that, although from a scientific point of view the accepted distinction into cases of epilepsy without and cases with loss of consciousness is arbitrary, it does not follow that from a clinical point of view such arbitrary distinctions may be not only convenient, but essential. We must have arbitrary standards for practical purposes, as I have just been illustrating by terms used for degree of implication of consciousness.

#### APPENDIX NO. 1 TO CHAPTER II.

I here give a quotation from Mr. Herbert Spencer's "Psychology," to which I have referred in Chapter II. (page 390), and to which I shall have to make frequent reference in later chapters. The quotation is full of matter of interest to medical men:—

"Memory, Reason, and Feeling *simultaneously* arise as the *automatic* actions become complex, infrequent, and hesitating; and Will, arising *at the same time*, is necessitated by the same conditions. As the advance from the simple and indissolubly coherent psychical changes to the psychical changes that are involved and dissolubly coherent is itself the commencement of Memory, Reason, and Feeling; so, too, is it in itself the commencement of Will. On passing from *compound reflex actions* to those actions so highly compounded as to be imperfectly reflex—on passing from the organically determined psychical changes which take place with extreme *rapidity* to the psychical changes which, not being organically determined, take place with *some deliberation*, and therefore *consciously*, we pass to a kind of mental action, which is one of Memory, Reason, Feeling, or Will, according to the side of it we look at.

"Of this we may be certain, even in anticipation of any special synthesis. For since all modes of consciousness can be nothing else than incidents of the correspondence between the organism and its environment, they must be all different sides of, or different places of, the co-ordinated groups of changes whereby internal relations are adjusted to external relations. Between the reception of certain impressions and the performance of certain appropriate motions there is some inner connection. If the inner connection is organised, the action is of the reflex order, either simple or compound; and none of the phenomena of consciousness proper exist. If the inner connection is not (a) organised, then the psychical changes which come between the impressions and motions are conscious ones; *the entire must have all the essential elements of a conscious action—must simultaneously exhibit Memory, Reason, Feeling, and Will; for there can be no conscious adjustment of an inner to an outer relation without all these being involved.*"(b)

#### APPENDIX NO. 2.

I find that I have already given a quotation on the Motor and Sensory regions of the brain in this journal, January 28, 1874. The following quotation is from an Abstract of my second Goulstonian Lecture (*Brit. Med. Jour.*, March 6, 1869):—

"He does not think it, *a priori*, likely that the optic nerve, any more than the radial nerve, would be represented in any one part of either or of both the cerebral

hemispheres, but in every part of each of them; and, excepting to an inconsiderable extent, only indirectly. Taking illustrations from disease, the kind of 'sensation disorders' we should expect from disease of the cerebral hemisphere would be spectral illusions—a disorderly reproduction of *very complex impressions*, which differ from defects of sight as a mistake in a word does from a cramp in the tongue. On this higher level, however, there will doubtless be some kind of localisation, and its most general character may be inferred. Since—as Lockhart Clarke has pointed out—the structure of the anterior convolutions does differ from the posterior, they must serve differently in mind.

"*Facts seem to show that the fore part of the brain serves in the motor aspect of mind, and we may fairly speculate that the posterior serves in the sensory.*"

"This speculation seems to me to accord with one of Ferrier's conclusions from his masterly experiments. The following is a quotation from a summary of his most recent researches (*Med. Record*, March 18, 1874):—'The whole brain is considered as divided into a sensory and motor region, corresponding to their anatomical relation to the optic thalami and corpora striata and the motor and sensory tracts.'

## A Course of Lectures

ON THE

### NATURE AND TREATMENT OF DEFORMITIES OF THE HUMAN BODY,

DELIVERED IN THE MEATH HOSPITAL, DUBLIN, BY

LAMBERT H. ORMSBY,

Surgeon to the Hospital, and Demonstrator in the School of Surgery Royal College of Surgeons in Ireland.

#### LECTURE VIII. (Continued from page 354.)

### DEFORMITIES AND DISTORTIONS OF THE HEAD AND FACE.

DEFORMITIES affecting the head or cranium are by no means so common as might be expected, and when they do occur it is more or less dependent on the gradual evolution and development of the brain. Some portions, however, of the bones of the cranium may be deficient, and in some cases there is no appearance whatever of the cranium at all, as found in the true *acephalous feti*; the parietal, occipital, and other bones are found occasionally imperfect, as seen in that malformation which is called *encephalocele*, which, in some cases, is similar to the arrest of development which is met with in the spine called *spina bifida*, and when occurring in the cranium frequently gives rise to *hernia cerebri*.

The shape and appearance of the cranium vary considerably, according to size, age, and national characteristics, for in some nations they have the power artificially of regulating the shape of the head. As this cannot be called exactly a deformity, I shall not consider the subject farther. The cranial walls are found in some instances to be very thick, in others very thin, and on some heads can be distinctly seen, although there are developed more or less on all heads certain bumps or enlargements, which offer great inducement to the exhibition of the phrenologist's powers in allotting to each bump a supposed known quality or instinctive propensity, so much so that every vice, moral quality, or animal propensity is supposed to have an allotted space on the cranium; and where certain bumps appear larger than usual, these phrenologists assure us that this increase and enlargement indicate most surely a greater tendency or proclivity to whatever vice, quality, or moral faculty the bump stands for, according to the phrenological catalogue. As I do most strongly believe in physiognomy, and the aptitude that some people have of reading a person's character by looking at their face, and can

(a) See foot-note (a), page 390.

(b) Spencer's "Psychology," vol. i., p. 493. (No italics in original).

detect when it exists as a character, amiability, determination, bad temper, &c., and a well-formed prominent forehead frequently demonstrates a greater development of the anterior cerebral lobes, and by this means a likelihood of the existence of "greater brain power," and thinking qualities.

In the same manner, I disbelieve very much what a confirmed phrenologist has taught himself to believe—who, I may mention, frequently belongs to a class of people who are utterly ignorant of the anatomy of the brain, or the osteological characteristics of the cranium—for in many cases, if they examined these bumps anatomically on the dead subject, they would find they were nothing more or less than heapings up of bony tissue for the purpose of strengthening the skull in those parts most prone to injury. And also in many cases they would find these bumps were not apparent on the internal surface of bone, and therefore did not correspond to the convolutions of the brain. Secondly, as the base of the skull cannot be felt during life, they assign no qualities to the eminences in this situation, which are very numerous, and really do correspond to the lobes and convolutions of the brain, and have a right to share in the allotment of qualities as well as other parts of the cranium. Thirdly, as many of the qualities assigned are developed and generated by the growth of years, and brought about by circumstances more than anything else, and are not innate principles: for example, what was the use of the bump of stealing before stealing was ever practised? and, in like manner, many other propensities might be adduced if it were necessary.

The disease hydrocephalus frequently causes great deformity to the skull, preventing the union of the various sutures and the closing in of the fontanelles. Mercury, syphilis, bony tumours, and inflammatory osseous affections, all have certain deforming effects; but each will be found under such diseases in the various works of medicine and surgery.

**Deformities of the Ears.**—The pinna and lobes are found to be occasionally enlarged and hypertrophied, and attain an immense size, whereas in others the pinna merely "sticks out," causing great annoyance to the person thus affected. In countries where the people are in the habit of inserting heavy rings and stones into the lobes of the ears, causing occasionally great distortion, appliances are made to remedy this deformity of the ears "sticking out," such as a steel band passing over the head and concealed by the hair, with small pads fixed to either extremity, which rest on the projecting portion of each ear. Disease, such as epithelioma, frequently affects this organ, destroying a great portion of the pinna and lobes by its ravages.

**Deformities of the Eyes and Appendages.**—We meet with a variety of acquired deformities in this situation. Rarely, indeed, are congenital deviations met with; and as the changes in the body of the eye are more the province of the oculist, I will confine my observations to the appendages of the eye, with the exception of squint, which can be in nearly every case improved by surgical operation.

1. *Strabismus*, or *squint*, signifies a permanent position assumed by the eye by the contraction of either internal or external recti muscles, hence termed convergent or divergent, the former being the most common. The internal squint is seen generally in young children, said to be acquired by the habit children get of turning their eyes in to look at the tip of their nose. It can be removed by division of the internal rectus muscle; and if the divergent, by the diversion of external rectus. Strabismus may also be caused by fright, or may be the effect of some obscure nervous affection.

**To divide the Internal Rectus Muscle.**—Place the patient, if old, on a low chair—if very young and unruly, lying on the back in the recumbent position—and chloroform administered to quiet the patient, as children are very troublesome, and will not generally keep quiet without some anæsthetic. The lids of the squinting eye are kept apart by the eye-speculum, or by the fingers of an

assistant. The surgeon then directs the patient, if conscious, to look outwards, and a small piece of the conjunctiva is pinched up with a forceps close to the insertion of the muscle into the sclerotic, and divided with a sharp pair of scissors; the sub-conjunctival tissue is then divided through, and the insertion of the muscle comes into view; a blunt hook is then passed between the tendon and sclerotic, in order to separate its attachment fully; it is then divided, and the operation completed. If the external rectus requires division the very same steps are carried out, with the exception of the primary incision into the conjunctiva, which is made in this case opposite the insertion of the external rectus into the sclerotic coat, at the external canthus of the eye, a little charpie, or wet lint, is applied to the eye, and bandaged up and not looked at for some two or three days. During the time of the operation you are recommended to bandage the sound eye, in order to have as full power over the affected eye as possible.

2. *Ptoxis*.—This is a deformity of the upper eyelid, and signifies a permanent drooping and inability to raise the upper lid when required. It may arise from many causes, among which I may mention—1. A redundant, or hypertrophied state of the upper eyelid; 2. Traumatic causes, as wounds, &c.; 3. Weakness or debility; 4. Paralysis of the levator palpebræ superioris muscle.

**Treatment for the First Form.**—A transverse piece of integument is removed from the lid on the outside, the edges of the wound brought together with suture, and this generally succeeds. If hæmorrhage occurs from the wound, the application of wet lint nearly always stops it. The non-affected eye after a few days ought to be covered with a shade, in order to make the patient use the affected eye as a necessity, and endeavour to lift the affected eyelid. A similar treatment, with modifications, will be applicable for the second form. The third and fourth will be better treated by constitutional medicines, and, locally, blisters and galvanism.

3. *Entropion*, or *Inversion of the Eyelids*.—This deformity is generally seen in the upper eyelids. There are three forms met with, according to Mackenzie—1. Traumatic; 2. Acute, or spasmodic; 3. Chronic, or inflammatory.

The first may occur from any traumatic cause, such as wounds, or scalds and burns, or the accidental introduction of some caustic substance, such as quicklime, or other irritating substance. The treatment of such will depend on the degree and variety of the accident, and some of the operations that will be afterwards mentioned will be applicable with slight modifications.

2nd—*Acute*, or *Spasmodic Variety*, may be compared with advantage, to the 3rd, or chronic, or inflammatory variety. The former is attended with little organic change in the affected lid, the latter is much changed; the former is found in people generally advanced in years, the latter in those younger; the former in healthy subjects, the latter in the scrofulous and debilitated; the former is generally confined to the external side of lid or integument, the latter generally due to inflammation of the conjunctiva.

**Treatment.**—In the acute, chronic, or traumatic form, the great point is to endeavour to remove the conjunctival or tarsal inflammation; in the acute, the application of collodion is recommended to be applied to the outside of the lid every two days, until a cure is effected; if not, an operation may be performed—1. A transverse elliptical piece of integument may be removed, and the cut surfaces brought together with sutures, and when union takes place the cure may be effected. 2. Janson, of Lyons, instead of a horizontal piece of skin, removes a vertical slip, and brings the edges together in the usual way. 3. Escharotics have been applied before now with advantage to cause a denuded and irritating surface, which produces contraction by the necessary granulation and cicatrization. 4. Mr. Haynes Walton insists on the removal of the ciliary portion of the orbicularis palpebrarum, believing the deformity to be due to its over-action. 5. Saunders cuts out the whole of the tarsal cartilage. 6. Ware believed

that a perpendicular incision through the whole thickness of the lid, opposite to either canthus, was the best operation. 7. Sir Philip Crampton made two perpendicular incisions on the inside of the lid, and this has since been modified by joining these two incisions in the form of an H. For further information on this subject you may consult with advantage the papers of Sir William Wilde, (a) Sir Philip Crampton, (b) or the works of Haynes Walton (c) and Mackenzie. (d)

4. *Ectropion*, signifying eversion, or turning out of either eyelids, I have generally seen in the lower, the result of contraction after burns, producing at times great deformity, caused by a thickening of the conjunctiva, induced by long-continued inflammation, the result of the various forms of muco-purulent ophthalmia. It may be also caused by the contraction of a cicatrix on the cheek, arising from burns, scalds, or some traumatic cause, or it may result after the healing of an abscess in the lower eyelid.

Treatment depends more on the inducing, or predisposing cause. If due to long-continued inflammation from irritation from ophthalmia tarsi, some diluted citrine ointment applied, or some astringent collyrium; if due to excoriation of the lid, owing to the application of irritating and constant discharges, everything applied to soothe the parts and remove the primary inducing cause.

There are various operations recommended, among which I may mention—1. To remove a V-shaped portion of the lid, bringing the edges together with sutures. 2. Removal of portion of conjunctiva. 3. Separation of material adhesions, and then removal of portion of conjunctiva. 4. Freeing the adhesions in every direction, and transposing the lid by drawing it up and maintaining it in the natural position by suture. 5. By denuding the skin by the constant application of caustics and irritating substances, for the purpose of inducing further contraction. 6. Transplanting new skin from the cheek. 7. Enlarging the separation of the lids by incision, to ease the tension and produce relaxation at both temporal and nasal extremities.

5. *Lagophthalmos* (or *hare-eye*) signifies an inability to close the eyelids, and may be caused by disease or paralysis of the motor nerves in this situation, a cold blast, or some other muscular or nervous derangement; it causes at times great irritation and inconvenience, for even during sleep the eye remains partially open, and dust and foreign matter are constantly getting into the eye. If it arises from cold, it generally gets well in a few days; if from paralysis it is very tedious—galvanism and blisters may be applied; if due to a cicatrix, this must be freed, and all tension and contraction of parts relieved by transposition of integument.

6. *Ancyloblepharon* signifies union of edges of the eyelids; it may be partial, or it is said to be very rarely congenital when the union is complete; it may also be caused by the explosion of gunpowder, or other explosive substances. I saw such a case—the affection remedied by incision and separating of the lids during their whole extent.

7. *Symblepharon* signifies union and adhesion of the lids with the globe of the eye; it may be caused by the same causes that produced the last deformity, or by the accidental introduction of lime and other irritating substances into the eye. This form is very troublesome to treat, as these adhesions may be freed, and the lids separated from the globe for the time, but they are nearly always sure to unite again. Very slight bands of adhesion may be divided without the slightest difficulty.

8. *Tumours of the Eyelids*.—We not unfrequently meet with small tumours and permanent swellings in this situation, producing very apparent deformity. There are a

great variety, among which may be mentioned warty growths, enlarged cutaneous follicles, vascular tumours, or naevi, small cystic and hydated tumours. There is a small tumour which I have frequently seen, and it is called the tarsal tumour, or chalazion; it varies from the size of a very small pea to the size of a bean; it can be seen on the outside, and when the lid is everted it can be also seen on the inside; it is filled with thick sebaceous matter. It is operated on from the inside of the lid, by making an incision into it and breaking up the contents with a probe. I operated a short time ago on a young lady for one of these tumours, and before she would allow me to touch her she made me promise I would not leave a mark behind, which, I need hardly say, was prevented by operating in the manner just mentioned. Other tumours and growths are operated on and treated in the same way as similar growths in other situations of the body, but in all cases great care should be taken to leave as little resulting mark or cicatrix as possible.

#### DEFORMITIES OF THE NOSE.

This organ in some people is found to be greatly enlarged, and by its excessive size and unsightly appearance by no means maintains or improves the symmetry and good looks of the face. The skin and areolar tissue are found greatly hypertrophied, until the nose sometimes attains three times its usual size, the sebaceous follicles are enlarged, and secrete in proportion more than usual, the nose assumes a deep red colour, and the large veins are seen coursing on the surface, giving it at times a mottled appearance. The common appellation applied to it is the "brandy, or port-wine nose," as it is generally supposed to arise in those people who are fond of high living, good wines, and the usual pleasures of the table, which, no doubt, is very true in most cases; but I have met with this hypertrophy in people of the most abstemious habits. Inherited gout frequently will give the nose such an appearance. In addition to the hypertrophy, we find encysted tumours and warty growths, which, if desired, can all be removed by operation. During the operation it is as well to pass a finger or spatula into the nostril, and with a sharp scalpel to pare the growth away slowly, keeping the knife close to the cartilage. There is generally profuse bleeding, which can be easily stopped by the application of strips of wet lint and styptics, and twisting the bleeding vessels. Disease frequently produces great deformity in this situation, such as lupus, syphilis, and epithelial cancer, which all have the effect, after a time, of destroying the nose completely, and leaving the patient very much deformed. The nose may be also removed by direct violence and accident, and has before now been completely bitten off. The treatment for such cases, when possible, is to construct a new organ, to remove the unsightly appearance of the patient, and for which purpose we find two operations recommended. Tagliacozzi, in 1597, performed an operation for the construction of a nose by taking a flap of skin from the inside of the arm, and hence called, from the originator, the *Tagliacotian Operation*; but owing to the uncertainty of union, the very tedious position of keeping the arm tightly bandaged to the nose, and maintained for nine or ten days, and the extreme difficulty of preventing movement of the arm, and displacement of the flap during sleep, the operation, I may say, has been completely given up for what is termed the Indian operation, which in every way offers great advantages, and far supersedes the other, not only in successful results, but by being easier in performance, and by giving the patient little or no annoyance when compared with the tedious annoyance of the Tagliacotian method. In the Indian operation the flap for the new nose is taken from the front of the forehead, which is brought down, made into the shape as near as possible of the original organ, and the flap is maintained in such a position by sutures and plaster, which after a time becomes firmly united, and removes to a great extent the unsightly deformity.

The steps of the operation and mode of procedure re-

(a) Wilde "On Entropion and Trichiasis."—*Dub. Journal of Medical Science*, March, 1844.

(b) Essay on the Entropion, by Philip Crampton, M.D. London. 1806.

quire a good deal of accurate judgment, to ensure taking the exact amount of flap and new material, in order to fit in evenly to supply the deficiency; if too little is taken there will be much stretching, and consequent manipulation, which in no way improves the future vitality of the flap, which runs a very good risk of sloughing. So in all cases it is better to take too much than too little, as if too large, the excess can easily be removed by the knife or scissors. The first step in the operation is the consideration of the size and shape of the flap to be removed from the forehead. This can be ascertained by taking a flat piece of gutta-percha and moulding it into the shape of the nose, then, immersing it in hot water, flattening it out on the forehead, and in that way the shape and size of the flap is marked out by ink, red chalk, or tinct. of iodine. The second step is the dissection of this flap from the forehead, and the incisions should commence from below upwards, in order that the outline should not be obscured by the consequent bleeding. The skin, areolar tissue, down to the epicranial aponeurosis, should be divided and raised, and the flap should be made to have a sufficiently large and deep attachment between the eyebrows, as that is the most important situation in the whole flap. The third step in the operation consists in paring what remains of the nose, so as to leave a raw triangular surface. The fourth step consists in twisting the flap on itself and bringing it down, fitting it into the deep triangular groove made, and maintaining it in that position by sutures. The edges of the space where the flap was removed from the forehead should be brought together as near as possible, but not altogether, or the tension will be so great as to cause the sutures to ulcerate through. The rest to be covered with wet lint. A small piece of lint steeped in carbolic oil should be inserted under the flap to endeavour to maintain its angularity, as, owing to the deficiency of the cartilages of the nose, it always has a tendency to become flattened. When all bleeding has entirely ceased, a little carbolised tow may be applied, to prevent suppuration, if possible, and also to keep the flap warm and prevent a likelihood of sloughing from loss of vitality. It is then gently bandaged up, and not disturbed for three days, and then merely to see the state of the flap, and remove the lint; but as little manipulation as possible should be observed. The sutures should be removed when adhesion has taken place. The fifth step consists in the separation or paring down of the root of the flap, as being turned on itself necessarily produced deformity. This may be done when complete lateral union has taken place. The sixth step consists in the formation of the columna nasi, which is taken from the upper lip. This flap is removed in very much the same way as the other, and, simple as it may appear, is found by far the most difficult part of the operation. Various portions of the nose may be alone deficient, and require to be remedied by surgical operation, which will vary according to the circumstances of the case. The nose is frequently congenitally deformed in double hare-lip, and frequently broken by blows and severe traumatic injury.

#### DEFORMITIES OF THE CHEEKS

May be caused by a variety of causes—such as, disease, accident, paralysis. Bony and fibroid tumours not unfrequently occur in this situation, growing from the superior maxilla, producing at times great deformity. Small encysted tumours may also occur in the substance of the cheek. Tumours growing from the antrum are occasionally seen, and are only cured permanently by complete removal of the cyst-wall. A great part of the cheek is frequently destroyed by cancer, and in earlier life cancrum oris is occasionally seen, causing the destruction of the cheek by its rapid sloughing and gangrenous effects. I have also seen great deformity in the cheeks produced by large nævi. My distinguished friend and colleague Mr. Porter, Surgeon to the Queen in Ireland, had a most remarkable case under his care, of a man with a large nævus extending all over one side of his cheek and lip, producing a most unsightly deformity. In all operations on the face care

should be taken when making incisions to endeavour to make them as small as possible, and in a direction so as to leave by their cicatrix as little deformity as possible.

#### DEFORMITIES OF THE LIPS

Are caused either by the congenital deformity, hare-lip, or by the ravages of epithelial cancer, cancrum oris, or the retraction of severe burns, as Fig. 22 very faithfully depicts. Epithelioma of the lip, when not far advanced, can easily be removed by surgical operation, leaving little or no deformity behind. The retraction of the lip from severe burn of the neck is also remedied by surgical operation, and greatly improved, as seen in the last-mentioned figure.

*Hare-lip.*—This is a deformity we occasionally meet with, and signifies a congenital fissure, or perpendicular division of the upper lip, and is named from a fanciful resemblance to the upper lip of a hare. It is caused by an arrest of development, and non-union of the central part of the lip to the lateral portions of one side or both. If the union is deficient on one side only, it is called *single hare-lip*; if the central portion is not attached on either side, it is called *double hare-lip*. In very early foetal life the intermaxillary or premaxillary bone is distinct, and separated from the superior maxillary, and corresponds to this portion of the lip, and, containing in it the incisor teeth, the lip tissue may be fissured, and also the bone, and the fissure extending backwards, giving rise to cleft palate which is nearly always present in cases of double hare-lip, in which case the central portion of the lip is attached to the intermaxillary bone, the two lateral portions to the superior maxillary bone, and this causes great deformity, giving the person a very different look when compared with a natural and well-formed waved outline of the lips, as seen in a symmetrical face—so much so that the union of the lips forming the mouth has been likened to a fanciful resemblance of "Cupid's bow." Most mothers will assign the deformity to some maternal impression they received during pregnancy. This deformity can alone be remedied by a plastic operation, and as there are such a variety of ways and means for operating, I will refer you to the subject in the various books of surgery, where you will find the different methods discussed at great length. In simple hare-lip, without complication, some surgeons say the younger the child is operated on the better; I should rather recommend, if possible, before teething, but not sooner than the third or fourth month. The edges of the fissure are pared and brought in perfect apposition; if they will not exactly correspond a little more is pared off, and they are then brought together and maintained in that position with hare-lip pins, and the figure of 8 twisted suture—some prefer the interrupted suture—which are removed on the fourth day, when adhesion has taken place. The pins are then withdrawn, and great care should be taken when drawing out these pins not to draw asunder the parts and break up the adhesions. In conclusion, I would strongly advise you to read a most valuable and able article on the subject by the late Mr. Maurice Collis. (a)

(To be continued.)

At the annual meeting of the King and Queen's College of Physicians, Ireland, held on October 19, Surgeon-Major T. M. Bleckley, M.A., M.D., C.B., Army Medical Department, was unanimously elected a Fellow of the College, *causa honoris*, in recognition of his services as senior medical officer of H.M. (hospital) ship *Victor Emmanuel* in the late Ashantee campaign.

(a) "The Æsthetic Treatment of Hare-lip, with a Description of a New Operation for the more Scientific Remedy of this Deformity." By Maurice Henry Collis, M.D. Univ. Dub., F.R.C.S.I., Surgeon to the Meath Hospital and Co. Dublin Infirmary, Examiner in Surgery Royal College of Surgeons of Ireland. (*Dublin Quarterly Journal of Medical Science* for May, 1868)

# ABSTRACT OF AN INTRODUCTORY ADDRESS DELIVERED AT THE LEDWICH SCHOOL OF MEDICINE, DUBLIN.

By JAMES E. KELLY, L.R.C.S.I.,  
Lecturer on Physiology in the School.

GENTLEMEN,—Deputed by my colleagues to deliver the address introductory to the session 1874 and 1875, I approach the task with a very natural combination of satisfaction and hesitation. The duty is most important, and as long as any value is attached to such deliveries it is worthy of the best efforts of the best among us. . . . Unless for those who believe either in the intuitive philosophy, or the incorrigible perversity of the rising generation, I can recognise no reason for what seems a neglect or oversight which appears yearly to become more general in this country. . . . The difficulty of introducing new topics into an inaugural address will be appreciated when I remind you that some fifty are delivered annually in Great Britain and Ireland. In this age of ours, in most things, to be original, one must, I fear, be revolutionary—a thing fit to the hand of the young and sanguine who have not “given hostage to fortune,” but deeply dreaded when years and responsibility steal upon us. While avoiding revolution and radicalism, let us be progressionists professionally, but let us be such with caution, as the architects of old, who ever built their temples on the surest foundations, and placed their idols on pedestals of bronze. Let us consolidate the ground while Providence will permit us; and should the fire of investigation ever demolish our superstructures and our theories, the basis we shall now lay, like the pot-earth under the old St. Paul’s Cathedral, will serve as a foundation for a nobler and loftier successor. . . . You should remember that the uneducated among you will bring contempt on our profession, disgrace to himself, and to his patients infirmity or death, for, as Dr. Gregory remarks, “there are many physicians in name, but few in reality and effect.” I do not seek for applause to-day, and consequently I shall not flatter you; I know most of you are capable of much more than many of you shall accomplish, and my intention is to place before you, once at least, in your student career, those disagreeable truths which, in consequence of being most frequently told us by our truest friends, are termed “home truths.” It is not my intention to inflict upon you an exhibition of my own erudition, or to trouble you with topics in which you can have very little interest until you shall have ceased to be students. I shall speak to you of yourselves, and with equal freedom of your good and of your bad qualities.

To treat of a subject philosophically, one must not make merely a superficial investigation, but he must examine its object and origin, its development and modifying circumstances. . . .

Your ultimate object is a noble, a God-like one, and, according as you succeed in attaining it, you also shall be noble and God-like; but if you fail, owing to your own neglect or wilful deficiency, you shall be no less degraded and ignoble. Your vocation is to assuage pain and diminish the ills of the flesh. This is your true object; but, alas! one of the rarest subjects of contemplation. Nothing is so short-sighted as the habit men have of making a goal of a proximate or intermediate occurrence, such as the preparation for some examination, or the acquisition of a means of subsistence. One object, the highest and the best, necessarily includes all the minor and intermediate advantages attainable in our profession. Hence, self-interest coincides with duty and humanity in urging you to aim at the highest condition of perfectability. Each one of you should place before him the highest position in your profession, and strive manfully to reach it. Thus you shall at least attain a position of honour in the land, and escape the slough of inefficiency and ignorance which closely environs the populous realms of mediocrity. . . . The function of a medical man is very complex, for in the consummation of his duty as the assuager of pain he must undertake

many other responsibilities, and frequently he holds not alone the lives of his patients, but their honour, their happiness, and their fortunes in his keeping. Those functions are inseparable; a patient’s disease is caused or complicated by some mental or temporal contingency, and it becomes the first duty of the keen practitioner to investigate every circumstance influencing his patient. He will often realise the Aristotelean dictum, “The philosopher should end with medicine, the physician commence with philosophy.” He should possess the combined attributes of the Christian, the gentleman, and the scholar, and he should ever remember that “physic is a glorious profession but a vile trade.”

The encroachments of the female sex on these prerogatives, which we were wont to regard as exclusively ours are becoming, more striking every year. With their insinuating invincibility of character they are gradually making head against all opposition, and if we can read the signs of the times aright, they will eventually gain their end. Considering the movement dispassionately, the question may be resolved into the following heads: Is a woman a rational being? Is she worthy of freedom of action? Should her privileges be decided by might or right? I think there cannot be a dissentient on these heads. Women, being rational, should have freedom of action, and the remains of gallantry bid us to listen to their pleas, even if our experience cautions us against arguing with them. Let us disclaim any participation in the unmanly threat that, by claiming an equality with us, women forfeit all right to our respectful consideration. I do not think the gentlemen of which our profession is principally composed shall, under any circumstances, forget what is due to themselves. The female population in this kingdom exceeds the male by some millions. We have a glut of educated single women, and it would be well if a greater number of legitimate fields were opened to their questionable ambition. I would extend to them the amount of liberty of action advocated for men generally by Mr. Stuart Mill—that which does not interfere with the welfare of the nation or of other subjects. I do not know that surgery or medicine would be included, because I cannot allow that their superior suitability for any branch of practice can be proven. There is hardly any branch of our profession which, on occasions unforeseen and sudden, if unfrequent, demands more of the male attributes of courage, decision, and physical strength, than obstetrics. In emergencies, it is said, the lady doctors would ask our aid; but the propitious moment may be lost, and even if assistance were at hand, it would be of no more avail than that of the nearest labourer, were we excluded from the practice of the art. Should the Legislature admit women to our profession, let us decide the question of precedence, not by unmanly threats and unworthy acts, but by a generous competition. By unwise opposition let us not afford a basis for the accusation that we fear women as competitors; but let us extend to them manly consideration, and even brotherly forbearance.

I shall sketch an extreme, but not an exaggerated example of the dangers which wait upon you. This year a student comes fresh from home or school influences, earnest, healthy, and pure. He makes the acquaintance of a few of his seniors, who engage to teach him the habits of good society. He is led from saloon to theatre, from bar to billiard-room, from Gin Street to Beer Street, and he is nightly allowed to find his way through all the perils of the city to some lonely lodgings in the suburbs. He quickly acquires the latest novelties in slang and comic ditties, and deems himself a man of fashion. Soon, in his turn, he becomes the instructor of ignorance, and thus acquires a proficiency and a polish, while he utterly neglects his duties. Anxious to instruct his pupil, and vain of his new acquirements, he becomes ostentatious and aggressive. He swaggers through the city with insult in his eye and aggression in his gait, exciting the contempt of every true man, and the disgust of all except the very meanest of his own class. He

forfeits self-respect, and with it depart honours, honesty, and decorum. In private his fellow-students laugh at, or with him, and then he should remember, as Hobbes remarked, that laughter is akin to contempt, for in public the more respectable avoid him, or pass him with a furtive and conscious recognition. In a few short months this boy is transformed into a premature drunkard, squandering his precious time, or, by contracting one fell disease, he brings upon himself a life of misery and a death of shame. Such an inauguration of an honourable career is not a fanciful picture described for scenical effect, but a sketch taken from real life. I cannot impress you sufficiently earnestly with the dangers of bad example; you will generally find that those most capable of affording it are students who have spent one, two, or more years unremuneratively. Their habits are in keeping with their deficiencies. The dissecting-room is their cigar divan, and gossiping is their chief employment. They practise pantomime in the lecture halls, which they would divert into theatres of variety. . . . The sympathy with our fellow-men, so essential in our profession, tends to the establishment of equality and fraternity, which often engenders amongst you undue liberty of thought and action. Another evil is the protracted period during which a student may be exempt from any test of his industry and knowledge. During the first term of your first year some of you may not exactly know the manner in which you should commence your studies, and diffidence, or want of interest, may prevent you from seeking information. Others among you think and feel that you lose little by subtracting a short period of enjoyment from a term of years. Thus, and similarly, Christmas and its vacation arrives, and another term finishes his first session, and such a student returns to his friends with a goodly stock-in-trade of flippancy and fast manners added to his original ignorance, hoping to escape detection, and longing for the ensuing session, that he may return to town to resume those agreeable pastimes with which he dissipated his first year:—

"If not so frequent, would not this be strange?  
That it is so frequent, this is stranger still;  
Of man's miraculous mistakes, this bears  
The palm."

A medical student should be of an age between the thoughtless schoolboy and the young man with habits of dissipation and a mind unused to study—he should have a natural vocation for his profession; possessed, at least, of moderate ability, he should have a sound preliminary education, and especially some knowledge of the art of reasoning and of natural philosophy. The remaining essentials are docility, industry, and conscientiousness. Most of you possess the majority of these attributes, and a little additional earnestness would compensate you for the deficiencies. . . .

Were I asked to mention the great fault of our system of medical education, I would unhesitatingly say that it lay in the preponderance of superficial theory over sound practical knowledge. We hear of practical anatomy, clinical medicine, experimental chemistry, &c.; but it would be well to devote to them much more care. Students apply themselves to those special branches very unwillingly, and in a superficial manner. Their excuse is that they are not remunerative at examinations. . . . Do not flatter yourselves that you have acquired useful knowledge when it merely enables you to stumble slipshod through an examination which, by accepting a shabby compromise, allows loose and worthless explanations to eke out awkward manipulations, and to pass muster for the practical, the true criterion of a man's real knowledge. Examinations at the termination of each session would effectually prevent this suicidal neglect, and in addition, would indicate the proper sequence or order to be observed in professional studies. This would possess for you an additional charm—that of facilitating the acquisition of your diplomas, for which, however, there should be a complete exami-

nation, comprising a selection from all the subjects of the curriculum which are of true practical utility, and irrespective of any previous test. Examinations, to be useful, must be incentives to progressive development. They should not be placed before the student in any possible sense as the ultimate objects of his studies. Rather than being ignoble goals, they should be as mile-stones placed on the highway of science, at fixed distances, to be passed in undeviating succession and determinate periods. This lies with the examining boards, and on them rests the responsibility of effecting progress. By rigidly separating the practical portion of the examination from the theoretical, and thus preventing an unscientific jumble of the two, and by dealing with the noble and sound principles of the several subjects, to the comparative neglect of minute details and useless "tips," they could wield a magic wand for the conversion of much dross into refined gold. Then an examination would be, as it should be, a test of a man's fitness to go forth as a student of Nature, to labour for the elucidation of its great truths. There is much dissatisfaction among you, owing to the kaleidoscopic changes which occur of late years in medical legislation. The senior student justly complains that he has entered the profession with the tacit understanding that the prospectus was his guide. One, two, or three years elapse, and suddenly the whole scene changes; new bye-laws are enacted, new schemes proposed: now he hears of fearful and unforeseen ordeals; now he is threatened with halves, now with thirds, until, in utter despair, he is perfectly resigned to be hanged, drawn, or quartered, to escape the racking uncertainty. Before any important changes are made in the prospectus, justice would demand that intimation thereof should be given equal to the time which is supposed to be occupied by the curriculum, and such is the practice of some licensing bodies. Here we have new ordeals added on a notification of a few months, with the questionable excuse that they are contained in the list of subjects recommended to the attention of the student. As well might you be suddenly called upon to undergo an examination in logic, or in natural philosophy, as in forensic medicine, chemistry, or botany, if hitherto these subjects were actually omitted from the system of examinations. I am not prompted to these remarks by any censoriousness, but with the hope that the free discussion of a subject which is so unstable as medical legislation may suggest to those in power a little consideration for the tempest-tossed student. Unquestionably changes are needed, but they must be radical and deliberate, and not the fitful outgrowths of transitory reaction.

The essentials for wisdom are observation and reflection: the former will bring you knowledge and learning, but can never give you the wisdom which results from the exercise of reflective powers; knowledge is to wisdom as the raw material is to the manufactured article—crude, and comparatively worthless. The duty of the young student is to cultivate his powers of observation, and lay up stores of material for the subsequent development of his reflective faculties. The student who has reached intellectual zero passes through the lecture-hall and the dissecting-room with his eyes and ears hermetically sealed, and his hands firmly rooted in those comfortable receptacles so conveniently placed by the obliging tailor. Day after day, year after year, he walks the hospitals and the school, a model of intellectual adamant, until, by some obscure process of illicit distillation, he is converted into a spurious article, which somehow is imposed as genuine on the public. Well may the great Gregory have said of such men, "I am sure I would not trust one paw of my great Newfoundland dog to a consultation of thirty, or of three hundred." Certainly it is no true ambition which prompts many men to neglect reason, culture, and skill, unless it is of examinational value.

As students of medicine, it is well that you should have a clear conception of the subject which you are supposed to learn, and with names of which you are already fami-

liar. They may be divided into two classes, termed primary and secondary, the former few in number, including those sciences which have a distinct individuality, as anatomy, chemistry, natural history, and natural philosophy; the secondary being such as result from a combination or fusion of two or more of those first mentioned, as physiology, materia medica, surgery, practice of physic, and a host of others. Therapeutics, or the treatment of disease, forms the capital of a noble Corinthian column, the pedestal of which is composed of the primary subjects I have just mentioned. If you follow me for a moment, you will quickly perceive the advantage of this classification. Physiology is principally based on anatomy and physics, materia medica on chemistry and natural history. Of the numerous subdivisions of therapeutics, we shall examine the structure of a few. Pathology is but the anatomy and physiology of disease. Practice of medicine is the offspring of pathology and materia medica. Surgery results from the union of anatomy and pathology. By a similar mode of combination the other divisions of your curriculum can be shown to result from the union of a few primary subjects. Is it necessary to tell you the rational order in which your studies should be pursued? Attend, in the first instance to the primary subjects, and with hardly an effort will you rapidly master their many combinations. This is the most rational, the most rapid, and the soundest method, and one which I would recommend to you most earnestly. Thoroughness is the great attribute of sound learning; it is by no rapid road that you can hope to attain an honourable position among your fellows, but by earnest work and fixity of purpose. No puerilities should be allowed to warp you from your high purpose, and your habits and demeanour should be in keeping with the dignity of your future. A grand motto, and one applied to the great Goethe, "Unhastening, Unresting," would be most suitable to you—ever eager to acquire knowledge, studying and investigating every object which presents itself to your senses—calmly, deliberately, and conscientiously weighing, contrasting, and classifying.

I wish to tell my junior friends the way I would have them study. Your great object should be—elucidation to the chemist standing at the edge of the great crucible of Chaos; not with the world alone, but with this universe, will chemistry coexist. In this also you should follow the rule of dividing your studies into the rigidly practical, and the acquisition of the highest principles, and thus you will favour your mental development while you learn chemistry thoroughly. At hospital, also, be practical in the extreme—cultivate your senses to the very highest degree. Do not seek for the probable, but thoroughly investigate what is with eyes and ears, with smell, and touch, and taste. Be free from prejudice, and critically test all descriptions, and accept of no statement uncorroborated by direct evidence. Pay little attention to treatment during your first year, or you shall tend towards quackery. Inquire chiefly about the principles which govern the various diseases, and never lose an opportunity of assisting your teachers. Thus you will gain their affection, and acquire a valuable familiarity with complicated details. I now have little time to speak to develop all your observative faculties. No circumstance should escape you. In the dissecting-room you prosecute your anatomical studies for the twofold purpose of learning the structure of the human body and cultivating keen observation and surgical skill. For it is in the dissecting-room you acquire the anatomical knowledge and the mechanical skill which, when guided by reason, constitute the fearless and successful surgeon. The desire to do a thing quickly is nowhere more injurious than in anatomy, or more certain to defeat its object. . . . Be self-reliant, make your own dissections, and you shall require no demonstrations. Seek after the great principles of the science, and you may almost entirely dispense with memory. You cannot attend with sufficient application to chemistry. During your studies and your subsequent career it will be your constant guide and reference. With every other science it is inseparably associated. It is, in truth, the

science of sciences, as no branch of physical science is so extensive, and still so unexplored and inexhaustible. When other investigators make their last discoveries they must hand them over for final elucidation to the more senior students. Although I have much to say, I shall confine myself to a few general remarks, as the particular subjects shall be efficiently introduced by the several lecturers. You should combine reason with observation, and constitute yourself perpetual interrogatories, never ceasing to inquire into the causation of facts submitted to you. Be thorough and bold in inquiry, but docile in learning. Freely acknowledge your errors and your ignorance, and thus cheaply purchase information. Refer every newly-acquired item of knowledge to the proper principles, and classify them carefully. Gentlemen, I thank you for your toleration in an address which introduced so many subjects to your attention, and still omitted so many others of equal importance. My object was to benefit you by forcibly reminding you of many things to be shunned and sought after. How well I have succeeded I shall judge by your future conduct at your studies, and I shall conclude with a quotation which ever appears to me most apt—

"Whatsoever thy hand findeth to do, do it with thy might, for there is no work, nor device, nor knowledge, nor wisdom in the grave whither thou goest."

### IDIOPATHIC TETANUS SUCCESSFULLY TREATED.

By H. TALBOT HIGGINSON, M.D., Donaghadee, Co. Down.

ON Tuesday, August 21, 1866, when medical officer of Lisburn Dispensary, I was called in to see Francis —, a boy 8 years old, a dispensary patient, who, I was told, had been labouring under very severe fits. I saw the boy in the evening, and found that he had first been attacked with spasms in his jaws the previous Friday morning—in fact he had awakened out of his sleep with them. When seen, the boy was perfectly conscious, risus sardonicus well marked, also opisthotonos, the belly was board-like, the bowels had been very constipated since the attack, the limbs and body were very stiff, and the toes pointed and turned towards the sole of the foot; jaws were partially open during the absence of the paroxysm, when the patient could with great difficulty and pain swallow small spoonfuls of milk, which he seemed to have a great craving for, and tried with his utmost to get down; the head was thrown back and unable to be bent forwards; he could sleep for ten or twenty minutes at a time, when the paroxysm would return, the jaws contracting forcibly, and the body bent backwards, the boy uttering at the same time a sort of scream through his teeth, and a frothy foam would issue from his mouth. The pulse was rather frequent, but much more so during a paroxysm. I diagnosed it as a case of tetanus, a number of which cases I had seen before, and inquired if the boy had sustained any injury or hurt of any kind; but he had met with none. His bowels had been regular up to the time of the attack, and he had not been troubled with worms, as far as I could make out; he had a good appetite, and was a strong, muscular, healthy boy up to the time of the first attack. The only thing I could attribute it to was, the boy said he had bathed in a river close by about six weeks before, and had remained in it until he found his teeth chattering, which might have set up some nervous inflammation or shock, which had gone on, ending in tetanus.

I at once returned home—which was two miles distant—and made up the following mixture:—

R. Ol. ricini, ℥j.;  
Spt. terebinthinæ, ℥j.;  
Ol. crotonis tig., gtt. xx.;  
Ol. anisi, gtt. x. M.

To be taken in teaspoonful doses ; and also an injection composed of—

R. Ol. ricini, ℥j. ;  
Spt. terebinthinæ, ℥iiss. ;  
Ol. crotonis tig, ℥j. M.

I then returned, bringing with me Maw's injection apparatus. When I got to the house I ordered one pint of thin gruel to be prepared, and in the meantime gave him teaspoonfuls of the mixture with a little milk, which the boy took when he had not a paroxysm. When the gruel was prepared I put about one-third of the injection mixture into it, which I threw up the bowel, when immediately the boy wished to relieve himself, which he did, but no fecal matter could be detected. After this the boy felt rather relieved, and was easier for a short time, but the paroxysms soon returned with the same severity. After remaining with him for about two hours I left, giving directions that the mixture should be given to him through the night until I should see him on the following morning, August 22. I then found he had passed a very restless night, and the paroxysms coming on very often, and even more severe. The pulse was much the same. I then ordered another pint of gruel to be prepared, and gave him another injection similar to the first, which seemed grateful to the patient, and he passed it immediately after, mixed with a small quantity of fecal matter. The boy seemed slightly relieved with this, as at the first. After remaining about an hour, during which time he had some very severe spasms, I left, ordering the mixture to be continued, saying I would return in the evening, which I did, bringing with me a further supply of the injection mixture, when I found the paroxysms had not occurred so often. I then ordered more gruel to be made, the boy at the same time requesting to have his bowels relieved, and gave him another injection, with the addition of one-third of infusion of Cavendish tobacco (℥j. to one pint of water), which also gave him some relief, some portion of fecal matter being distinguished in what passed. I then, after remaining about an hour, left, telling them to continue giving him the mixture, and that I would see him in the morning, August 23, when I found he had passed a very bad night, but the fits had not been so frequent since daylight. I gave him another injection, with the infusion of tobacco similar to the last, and after remaining some time, left, telling them to continue the mixture as before, and I would call in the evening. His pulse was, if anything, scarcely so frequent.

In the evening I found he had had some violent spasms during the day—almost every twenty minutes or half an hour. I then gave him another of the tobacco injections, which the patient expressed his desire to have, which relieved him for some time ; but the paroxysms becoming more severe, I thought I would try how chloroform, which I had brought with me, would subdue the spasms, and kept him under its influence for about two hours, after which time, as the influence went off, he took a most violent paroxysm, his tongue being caught between his teeth and violently bitten, so that the blood ran out of his mouth. I had then to get the handle of a spoon between his teeth and lever his jaws so far open as to relieve the tongue, which after some difficulty I succeeded in doing. This paroxysm lasted half an hour. In an hour's time after the severe spasm had subsided, when he was more composed, I administered another tobacco injection which was retained scarcely any time, but when it came away, was mixed with fecal matter, and gave him great ease, but the belly from the first up to this time had been very hard. After remaining about half an hour longer, I left, ordering him to have an injection of gruel, tobacco, &c., given him every three hours, until I saw him again. Next morning, August 24, I found he had passed a much better night, the spasms not so frequent, the belly not so hard, and altogether he appeared better, the injections having given him great relief. I now ordered him to have as much milk and

beef tea, given him in small quantities at a time, as he could take, and injections of gruel or beef-tea given him three or four times during the day, and in the evening I gave him another tobacco enema, which came away with some fecal matter.

Next morning, August 25, I found he was much better, the spasms not so frequent, and he was able to swallow better ; the belly also not so hard. After this he continued to improve, and was given injections of beef-tea and gruel alternately, and as much milk and beef-tea as he could take by the mouth, with an occasional injection of tobacco if any symptom of spasm made its appearance, until he was free from them altogether, and could eat, which was not for about six weeks, when he got quite strong, and some months after had an attack of scarlatina, which he got over very well, and I believe he is now a strong, healthy boy.

## Transactions of Societies.

### CLINICAL SOCIETY OF LONDON.

FRIDAY, OCTOBER 23RD, 1874.

PRESOTT HEWETT, F.R.C.S., President, in the Chair.

Mr. BRUDENELL CARTER described a case of

BRAIN-DISEASE SIMULATED BY OVERSTRAIN OF THE CONVERGENCE MUSCLES OF THE EYES.

The patient, a young gentleman, was interrupted whilst reading for honours at Oxford, by double vision and vertigo, followed, if the effort to read were continued or soon resumed, by sickness, palpitation, and intense headache. These symptoms were attributed to some obscure affection of the brain, and the patient was directed to leave the university without taking a degree. He remained for some time at home, under medical treatment, without improvement, and, on coming to London for further advice, was told to take a voyage to Australia and back, in order to rest his brain. He did so, but returned no better, and was then advised not to enter into business, and to abandon his engagement to marry. Mr. Carter was consulted about the case, in order that he might say whether the ophthalmoscope revealed anything abnormal in the cerebral circulation. He found the patient to be very short-sighted, and that he had never worn spectacles. In reading, he held his book seven inches from his eyes ; and Mr. Carter ascribed the symptoms to inability to maintain the degree of convergence for many hours. He ordered spectacles to be worn constantly, and reading to be practised at a distance of eighteen inches. In three weeks, the patient returned cured, with his wedding-day fixed and his arrangements for entering into business completed. In his concluding remarks, Mr. Carter said that the case, though exceptional, was exceptional only in degree, and that many patients suffered from headache and other symptoms due only to impaired harmony of the ocular muscles, or to inordinate exertion of some of them. He urged that, in every case of obscure head-affection, the state of refraction, of vision, and of the muscles, should be carefully investigated ; at all events, before a patient was sent to Australia, or advised to abandon his position and duties in life.

Dr. HUGHLINGS JACKSON considered Mr. Carter's paper to be as interesting to physicians as to ophthalmic surgeons. He (Dr. Jackson) referred to a case in which hypermetropia, which was an indirect cause of nervous troubles, had been, by several eminent ophthalmic surgeons and by himself, misinterpreted. It disappeared when appropriate glasses were worn. Since then, he had always considered the state of the refraction of the eyes, as well as the state of the fundus, in patients who had what might be called minor cerebral symptoms. He referred to another case he had seen with Mr. Carter, in which severe headache seemed to be fairly attributable to hypermetropia and astigmatism. He considered that cases of ocular palsy were for the study of the nature of vertigo, the simplest of all cases. It was clear, from these cases, that vertigo was

a motor symptom. It was not due to double vision, as commonly supposed, since it occurred on use of the paralysed eyeball only—that is to say, under conditions in which double vision was impossible. Yet, as a matter of fact, vertigo, in physicians' practice at least, was not commonly met with in cases of ocular palsy. This was owing to the fact that, in the case of the sixth nerve, the patient, so to speak, dodged the paralysis by holding his head stiffly inclined; and, in the case of the third nerve, to the fact that the paralysed eyeball was covered by the drooping lid. In the latter case, the patient did not reel nor feel giddy, but, if he closed the good eye, and if the paralysed lid were upheld, he would, when walking, feel giddy, would reel, and might feel sick. The vertigo was due to "erroneous projection." There was a duplex condition. There was over-estimate of the range of a movement of the eyeball intended but not really performed, and action of movements of locomotion, in accordance with that false estimate, and thus overaction of them.

Dr. POORE thought Mr. Carter's case resembled cases of chronic fatigue of muscle, such as was seen in writer's cramp. As in that disease, the muscle used for prehension of the pen, the first dorsal interosseous, was put upon the stretch for hours at a time; so in Mr. Carter's patient the internal recti were put into a condition of overstrain. And, as in writer's cramp, the muscles refused to act directly the pen was put into the hand, and headache, &c., ensued, so in this patient, who really had "reader's cramp," the muscles refused to act; as soon as reading was attempted, double vision was produced, which recalled the symptoms of former attacks, and headache, vertigo, &c., followed.

Dr. RASCH had witnessed a case of vertigo, nausea, &c., simulating serious disease of brain, in which a large clot was discovered in the external auditory canal. This having been syringed out, the patient immediately recovered. He had often known syringing of the ears to relieve such cases.

Mr. CARTER, in reply, stated that this observation simply confirmed the conclusion at which he had arrived, that no stone should be left unturned in the investigation of all the causes which might produce symptoms similar to those that had occurred in the case which he had just read.

Dr. SOUTHEY read some notes of an interesting case of  
CANCER OF STOMACH AND LUNGS,  
which gave rise to remarks by various members.

A CASE OF THROMBOSIS CAUSED BY A NEEDLE  
was read for Dr. H. THOMPSON.

A young woman of hysterical temperament was admitted into Middlesex Hospital with febrile symptoms of two days' duration. She had pain in the back, languor, and loss of appetite. There was also pain and tenderness in the right iliac region and across the hypogastrium; and, indeed, the whole surface of the trunk appeared to be unnaturally sensitive. There was a systolic murmur at the apex, and the heart's action was tumultuous, but there was no history of rheumatic fever. The day after admission, she became wildly delirious, with a pulse of 160, and a temperature of 105 deg. Fahr., followed in the course of two hours by profuse sweating. On the following day, she had a rigor, with a temperature of 107.4 deg. Fahr., again followed by profuse sweating, and a fall in the thermometer. This rigor was repeated by others, so that, during the fifty-three days she remained under observation, there were rigors on nineteen; mere chilliness of four; both, as a rule, being followed by sweating. Again, vomiting or faintness either concurred with the paroxysm of shivering, or played the part of its representative. Whatever the mode of manifestation, the temperature at the time of the outbreak almost always culminated in a peak—on six days, at 105 deg. Fahr. or more; on twenty-six, at 104 deg. Fahr. or more. Twelve days after admission, phlegmasia dolens, with conspicuous enlargement of the superficial veins, appeared in the left lower extremity, and forty-two days after in the right, and then remained until the death of the patient. About the time of the first appearance of the phlegmasia, she presented symptoms closely resembling those of pericarditis; and throughout the case she complained of aching pain in various regions of the spine. Finally, after a protracted period of delirium, accompanied by profuse diarrhoea, she sank exhausted, and died on the fifty-third day after admission. The treatment consisted, in the main, in the administration of quinine in large doses and in the free use of stimulants. The blood was twice examined during life, and the white corpuscles were found to be inordinately increased. At the post-mortem

examination, there were found to be numerous extravasations beneath the lining membrane of the third ventricle of the brain, but this organ was not otherwise diseased. In the chest, there were subpleural ecchymoses over both lungs, and the organs were oedematous. There was one or two old white patches on the surface of the heart. The mitral valve was thickened, and presented a chain of small vegetations along its auricular margins. In the abdomen, the inferior vena cava, from its commencement to the junction of the renal veins, was filled with a partially decolorised clot, adherent to the wall of the vessel, and channelled through its centre. At its commencement, just above the junction of the iliacs, the vessel was filled with dirty brown matter; and in the midst of this a needle was noticed resting in an oblique direction, with its eye pointing downwards and slightly to the left, in close relation to an opening in the back of the vein, about an eighth of an inch in diameter. Immediately above this, another opening existed, measuring one quarter of an inch in diameter. Through these apertures, the body of the fourth lumbar vertebra could be felt denuded of its periosteum. The left common iliac vein was filled with a brownish-red clot of moderately firm consistence and slightly adherent. The left external iliac and left femoral veins were as small as crow-quills, and were completely occluded by a whitish fibrous plug, which could not be detached from the wall of the vessel. The right common iliac, right external iliac, and right femoral veins were obstructed and narrowed by a tough fibrous-looking layer, firmly attached to the lining membrane. Immediately to the left of the third lumbar vertebra was an abscess, in which a second needle was found, lying obliquely across the body of the vertebra, the surface of which, however, was not eroded. The liver was engorged with blood. The spleen contained several infarctions, one about the size of a marble, softened in its centre. The intestines were much injected; the mucous membrane was the seat of extensive catarrh. The kidneys were normal.

## THE MEDICAL SOCIETY OF LONDON,

MONDAY, NOVEMBER 2, 1874.

VICTOR DE MERIO, Esq., F.R.C.S., President, in the Chair.

MR. P. Y. GOWLLAND showed a specimen of  
A RARE FORM OF POLYPUUS OF THE RECTUM TAKEN FROM A  
FEMALE ET. 41.

The woman had suffered when a child from some bleeding, but had not taken much notice of it until ten years ago, when a growth appeared, which increased considerably, and gave rise to tenesmus and bleeding. Mr. Gowlland removed the tumour, which, on examination, proved to be of the follicular variety, common among children, but rare in adults. He exhibited drawings of this and several other polypi.

Mr. ALLINGHAM stated, in reference to the present case, that there were three kinds of polypi: (1) the follicular condition of epithelial growth, and usually found among children; (2) the polypus of adults, which contains more fibrous element; (3) fibrous polypus, resembling fibroid tumour of the uterus. He did not agree with Mr. Gowlland that the first form was extremely rare in adults, for he remembered several cases among them—one where the patient's age was 34; but doubtless this form was most common among children.

Dr. ROUTH stated that follicular polypi were not so rare among women, whatever they may be among men.

Dr. WILTSHIRE asked if much pain accompanied these cases.

Mr. GOWLLAND, in reply, said that the follicular form of polypus was remarkably free from pain; but in true fibrous the pain was great, and there was a strong tendency to contraction.

Dr. SANBORN exhibited

SOME GELATINE DISCS OF MORPHINE AND ATROPINE FOR  
HYPODERMIC INJECTION.

Each disc contained 1-6th or 1-3rd of a grain of morphine or 1-120th of a grain of atropine, and was capable of solution in a little hot water in a spoon. He advocated their use on account of their portability and their keeping better than the hypodermic solution generally used, in which fungi were apt to form.

Mr. WM. ADAMS then read a paper on

**A CASE OF STRANGULATED FEMORAL HERNIA REDUCED BY LARGE INJECTIONS OF OIL, AFTER STERCORACEOUS VOMITING HAD EXISTED MORE THAN THREE DAYS.**

On Thursday evening, the 13th March, 1873, Mr. Adams was sent for by Dr. Kavanagh, of Deptford, to a case of strangulated femoral hernia in a man aged 48 years. The hernia was on the left side, small, but well defined, and the symptoms were severe; stercoraceous vomiting had set in at 4 p.m. the day previously. All efforts to return the hernia by taxis, aided by the warm bath, were unavailing. The symptoms commenced with pain in the abdomen, on Tuesday, chiefly referred to the upper part and the right side. He had no pain in the situation of the hernia, and therefore the patient believed that the obstruction was not in the hernia, but higher up. The hernia had existed for thirty years, varied in size, but had never been completely reduced, neither had he ever worn a truss. Operation was at once recommended; but the patient obstinately refused to submit to it, principally from his conviction that the obstruction was higher up in the bowels. On Friday the patient remained in the same state; stercoraceous vomiting continued every ten minutes, and all nourishment in the shape of beef-tea, brandy, &c., was rejected as soon as taken. He still refused the operation. Dr. Kavanagh now resorted to a method of injecting large quantities of oil, by which he had successfully treated three other cases of intestinal obstruction, accompanied with stercoraceous vomiting, but without external hernia. Each injection consisted of 2 quarts of olive oil, 3 oz. of castor oil, and 3 oz. of turpentine, mixed together. The injecting was slowly performed, and a gum elastic tube, about ten inches in length, was used. In the present case the injection immediately returned; and in the other cases the injections were not retained at first, but after being repeated at intervals they were retained. On Saturday afternoon, the 15th, Mr. Adams saw the patient again, with Dr. Kavanagh. The symptoms were the same, but extreme exhaustion had set in; abdomen tense, and tenderness on pressure, chiefly over the central and upper part, but absent at the seat of hernia. The condition of the patient appeared to be hopeless; but between 11 and 12 p.m. Dr. Kavanagh again resorted to the oil injections, and about 2 a.m. on Sunday morning the hernia was spontaneously reduced. About 4 a.m. the bowels were copiously relieved, and all the symptoms gradually disappeared; beef-tea and brandy were retained on the stomach, and the progress toward recovery was rapid and complete. He has worn a truss ever since, and is now in good health.

The PRESIDENT mentioned a case which he had seen with Dr. Richardson where an injection tube 20 inches long was used, and olive oil largely thrown in.

Mr. CARR JACKSON said that the diagnosis of intestinal obstructions from fecal accumulation and from hernia could not be too distinctly made. He remembered a case where the patient expressed himself as "stuffed" with feces, and operation for hernia had been suggested, and olive oil to the extent of 5 flasks was thrown in through an O'Beirn's tube, and a quantity of disintegrated fecal matter came away. The patient died; and the rectum was found to be stuffed with fecal masses, and part of it perforated from the distension, giving rise to peritonitis.

Dr. J. M. FOTHERGILL asked if, previous to other means, black coffee had been given, as he had read of its use being successful in some Italian cases.

Mr. ROGERS HARRISON thought the author had confused cases of intestinal obstruction from accumulation with those of intestinal hernia, and that the patient seemed to know more about the matter than the surgeons. Was it likely that hernia existed (as mentioned in Mr. Adams' case) for ten days without giving rise to further general symptoms?

Mr. NAPIER asked whether the injections were used warm or cold?

Dr. WILTSHIRE discussed the diagnosis in this case, and stated that the presence or absence of suppression of urine would give the key to the position of the obstruction. He was in favour of the prompt use of turpentine injections, and against their repetition, as liable to produce strangury. He preferred gruel in place of oil on account of its cheapness, and thought it was very important to make out whether ulceration was or was not present in these cases.

Mr. ROYCE BELL agreed with Mr. Adams as to his diagnosis of hernia in the present instance, and related a case which came under his own charge that was confirmatory.

Mr. GOWLLAND asked what enema apparatus was used, and described one that he preferred.

Mr. J. SEBASTIAN WILKINSON said it was probably a case of strangulated hernia where the omentum as well as the gut was involved, and this accounted for its return under the influence of injections.

Mr. MAUNDER remarked that these injections acted by dilatation of the intestine, or by inciting peristalsis. In many cases of hernia he advocated opening the abdomen above Poupart's ligament, passing the finger and thumb in, and freeing the intestine from within. This he had seen done in more than one case.

Mr. ADAMS, in reply, said that there was no doubt about the existence of hernia in the case he had related, as it could be felt, and was accompanied by stercoraceous vomiting. It was reduced of itself. It was possible that there was some other condition like intussusception present; but the hernia fully accounted for the symptoms. Coffee was not tried. Oil was used cold, and the ordinary stomach-pump with an O'Beirn's tube employed. Most of Dr. Kavanagh's cases were of obscure obstruction, but the one he had related was of hernia; and although he (Mr. Adams) had long been familiar with the use of olive oil in injections, he was not aware of its employment in such large quantities.

WEDNESDAY, NOVEMBER 11, 1874.

**THE ACTION OF DRUGS.**

**II.**

IN a former article on this subject we gave some details of the researches of Professor Hughes Bennett and his committee, confining ourselves to the first portion of his report. We now follow up the subject by continuing our analysis of the very important experiments carried out by the committee in order to determine whether Calabar bean and atropia antagonise each other.

Professor Bennett details various experiments with Calabar bean and sulphate of atropia on rabbits, and here we call attention to the fact that in one experiment a rabbit weighing 4 lbs. died in nineteen minutes after  $\frac{1}{2}$  grain of atropia, while another one of same weight recovered after taking the same quantity; also one weighing 3 lbs.  $7\frac{1}{2}$  ozs. recovered after taking  $\frac{1}{2}$  grain. This seems to indicate that weight is a rather unreliable basis on which to estimate the dose.

Further, Table 10, Experiment 133, shows that a rabbit weighing 3 lbs. 8 ozs. died in seventeen minutes after 6 grains of atropia, while (Experiment 143) one of same weight recovered after taking 18 grains. Referring to Dr. Harley's "Vegetable Neurotics," and Messrs. Burness and Mavor's "Specific Action of Drugs," we find that 1-48th of a grain to 1-24th of a grain produces physiolo-

gical effects in a dog, and 1-12th of a grain in a horse, and 1-120th to 1-96th of a grain in man; yet Prof. Bennett states that up to four or four and a half grains no symptoms whatever could be observed in rabbits. "With from four to six grains, there occurred dilatation of the pupil; uneasiness, as manifested by the rabbit moving restlessly about; respirations reduced; and the cardiac impulses were accelerated in number. With from six to fourteen grains, in addition to the symptoms noted above, there were, paralysis, more marked in larger than in smaller doses; slight quivering of special groups of muscles; violent starts of the whole body; and a drowsy condition. With from fourteen grains to twenty-one grains—the minimum fatal dose—in addition to the foregoing symptoms, there were increasing paralysis, and the respirations were reduced both in number and in depth. The animals died, in those cases in which fatal doses had been given, with severe spasmodic convulsive starts and twitchings. The action of the heart and the depth and frequency of the respiratory movements decreased until life was extinct."

Bearing these facts in mind, we see that weight has far less to do with the effect produced than the development of the nervous system; also, how the symptoms vary in different animals, for Dr. Harley (p. 201) says that in the dog the influence on the heart is more strongly marked than in the horse, while the cerebral effects are much less decided; moreover, in comparison of its size, the dog bears a much larger dose than the horse. However, all these experiments serve to show that certain drugs influence certain parts in *all* animals, although not necessarily producing the same train of symptoms in each. And for this reason such experiments are of great value, as, by throwing light on the physiological action of drugs, they at the same time indicate, to a certain extent, the range of therapeutic action, and enable us to use medicine more scientifically and less empirically.

But to pass on. There is one point to which we would like to call attention—viz., it is stated that three-quarters of a grain of extract of Calabar bean is the minimum fatal dose, and to antagonise this only three grains, and in one case four-and-a-half grains of atropia were given (Experiments 152-154). Yet it is stated (*vide* above) that 20 to 21 grains is the minimum fatal dose, and that four to six grains are required before any physiological effect is produced, and that with four grains no symptom whatever could be observed. Such being the case, it is difficult to see how one could expect (Experiment 152) four and a half grains of atropia to antagonise one and a half grains of extract of Calabar bean. The reason why such small doses were given is not stated.

Prof. Bennett remarks, in reference to Table 11 (which records the effects of Calabar bean and sulphate of atropia):—"It will be observed from this table that in one case (No. 148) the rabbit survived for five days. It was very ill for twenty-four hours; it then apparently became well; but on the fourth day it showed no inclination to take food, and on the morning of the fifth day it was found dead in its box. All the other cases died in periods varying from fourteen to sixty-two minutes after receiving the injection of Calabar bean extract. In every case life was prolonged by the use of the atropia, and the symptoms were modified." Yet it is a point worthy of note that one rabbit weighing

3 lbs. 8 ozs., after receiving half a grain of atropia and one grain extract of Calabar bean, was ill for twenty-four hours, and *only* died on the *fifth day*; while one weighing 5 lbs. received three grains of atropia and one and a half grains of extract of Calabar bean, and died suddenly, after seventeen minutes, with slight convulsions; and another, weighing 6 lbs., received four and a half grains of atropia and one and a half grains of extract of Calabar bean, and died in twenty-five minutes, with severe convulsions. Thus it would seem that, when the proportion of atropia was increased, death was hastened in proportion. And again, in Experiment 161, to a rabbit weighing 3 lbs. 4½ lbs., one and a half grains of extract of Calabar bean, followed by three-quarters of a grain of atropia, was given, and death ensued in 100 minutes. Yet (Experiment 165) to another rabbit, weighing 3 lbs. 9 ozs., was given one and a half grains of extract of Calabar bean, followed by one grain of atropia, and here death ensued in *twenty-nine* minutes; and in Experiments 169, 170, and 175, only three-quarters of a grain of atropia was used with success to antagonise three-quarters of a grain of extract of Calabar bean. All these experiments would seem to indicate that where the atropia is given to antagonise Calabar bean in larger doses than three-quarters of a grain, death is hastened than if smaller doses were given.

We comment on these points, for no notice seems to have been taken of them by the experimenters. These experiments at least serve to bear out Dr. John Harley's statements, for he says (p. 217) that in moderate doses atropia is a stimulant to the sympathetic nervous system and circulation, *but* in large doses diminishes the force and activity of the heart. Such being the case, we can quite understand life being prolonged by a small dose, as in Experiment 161, and hastened by an increased dose, as Experiment 165. This dual action of drugs seems to have been overlooked.

Professor Bennett now passes on to record various experiments on rats, which only differ in showing that the minimum fatal dose for a rat is from five to five and a half grains; and at the end of the report he thus sums up:—

"It is evident that the antagonistic influence of sulphate of atropia on the effects of extract of Calabar bean is not nearly so well marked as that of chloral hydrate as an antagonist to the effects of strychnia. Even after the introduction of sulphate of atropia, the symptoms produced by the previously injected extract of Calabar bean continue to be well marked. The animal seems to be extremely ill. There are salivation, twitchings of the muscles, and perhaps slight convulsions. This state of things may continue for several hours, and the animal slowly recovers. In the case of strychnia and hydrate of chloral, if the animal be kept undisturbed, it may not exhibit a single indication of the presence of the strychnia, and it becomes roused from the effects of the hydrate of chloral as if it had received it alone.

"The experiments made on rabbits clearly show that sulphate of atropia does antagonise fatal doses of extract of Calabar bean, but within a very limited area.

"1. Sulphate of atropia antagonises to a certain extent the fatal action of Calabar bean.

"2. The area of antagonism is even more limited than Dr. Fraser has indicated in his paper already referred to.

"In all the experiments made in connection with this branch of the inquiry, it was found that so-called antagonism existed within very narrow limits. The danger was, not death by too great a dose of sulphate of atropia, the supposed antagonist, but death from the effects of the

extract of Calabar bean. In this respect, there was also a marked contrast to the action of hydrate of chloral on the physiological effects of strychnia. In the latter instance, the danger evidently would be, in a case of poisoning by strychnia, to give too large a dose of hydrate of chloral; whereas, in the case of poisoning by extract of Calabar bean, it would apparently be very difficult to arrest its effects by sulphate of atropia, because a small dose of the latter produces little effect (at all events in rabbits), and the effects of the extract of Calabar bean are so violent as soon to destroy life. It results that, for all practical purposes, atropia, as an antidote of Calabar bean, is useless, and not to be compared with the effects of chloral hydrate, as shown by the committee under the next head."

With these conclusions we quite agree, and fully appreciate the value of these experiments in establishing the fact that for practical purposes atropia is an uncertain antagonist to extract of Calabar bean, at least, in *rabbits* and *rats*.

### HOSPITAL SATURDAY.

WE are glad to observe that almost the entire press, both lay and medical, agree with us as to the anomalous character of this fund as at present constituted and managed, or, more properly speaking, mismanaged. From the very first we questioned the desirableness of having two distinct organisations, opposition charity schemes, as they might be termed, one representing the contributions of the Church-going community, the other of that section whose boast it is never to be seen inside the walls of any place of worship. The Mansion House Committee, fully alive to the position of affairs, and anxious to avoid even the possibility of discord, endeavoured to enlist the co-operation of the Committee of the Saturday Fund under their banner, but to no purpose. A factious few had set themselves up as leaders of working-class opinion—the bankers of working men's pence—with what result we need not repeat. We may, however, be pardoned offering a suggestion for future operations: Let each employer of labour be his own committee-man for a working men's fund; let each working man, as he receives his weekly wages, return one penny to his employer, such money to be paid into the Post Office Savings Bank, or into some general treasury where the investment will be safe and a small interest obtained, and the result will be, at the end of the year, the magnificent total of over £100,000, without the vexatious deduction of nearly a fourth of the whole for working expenses, or the discredit of having set aside the vagrancy laws of the land for the purpose of street-begging. We know enough of the working classes to believe that, were this idea put before them in a proper light, they would readily acquiesce; not one of them would miss a penny, and the pride of having contributed so much towards Institutions which are at all times open for their benefit would in itself be a sufficient reward.

Although agreeing with the remarks contained in our last, a leading lay contemporary took exception to our figures when we stated "that the working classes had not contributed the tenth of a farthing per man." Our contemporary evidently did not read the context. We based our calculations upon the last census of 500,000 working men, and said that if each man only gave one penny per week for twelve months, it would have yielded over £100,000, instead of which they had not contributed the tenth of a farthing per man, i.e., of course on the same calculations per week for the twelve months. We maintain the accuracy of our figures: the tenth of a farthing per week for the twelve months would yield £2,703 6s. 9d., and, as this represents about half the sum raised by the Hospital Saturday Committee, and a fair proportion of the whole fund contributed by the working men proper, our calculations are not very wide of the mark.

## Notes on Current Topics.

### The Cost of Disease in Sheffield.

"THE Value of Health" was the subject of a lecture delivered last week by Dr. Hime at the Sheffield School of Art, and in treating it he made some very interesting statements relative to the prevalence of disease in the town. Mr. H. C. Sorby, F.R.S., presided at the lecture, which was given in connection with the Sheffield Literary and Philosophical Association. The lecturer referred to the great advance which had recently been made in sanitary science, and stated that the mortality in London had decreased from 42 per 1000 when the population was only 530,000 to 22 per 1000 at the present time, when the inhabitants numbered 3,000,000. Then, alluding to the expense of disease in Sheffield, he assumed the cost incurred by a sick man to be two shillings per day, and affirmed that a working man earning five shillings per day when in good health incurred a very serious loss when he had to spend the former amount in consequence of sickness. The average number of six days per head of the population was from 19 to 20. Sheffield had a population of 270,000, and reckoning 20 sick days for each person, 5,400,000 sick days were obtained, which, at 2s. per day, represented a cost of £540,000 per year. The average mortality in Sheffield for three years had been 27 per 1000, which, in a population of 270,000, gave 7,314 deaths per year; and if the proportion of cases to deaths in the hospital was the same as that in the town, almost the same number of sick days would be the result. But what advantages would the town derive from a diminution in its mortality? The mortality in Sheffield was at the rate of 27 per 1000, compared with 22 per 1000 in London. The present rate of 27 per 1000 gave 7,344 deaths in Sheffield annually; but if the rate of mortality was only 22 per 1000 the number of deaths would be reduced to 5,940, and the saving of 1,404 lives thus effected would result in the saving of £88,303 per year. The loss to the town by deaths from fever was at least 20,230 for the three years in which 691 deaths had resulted from that disease, but that calculation did not include the cases of fever which had not proved fatal. The lecturer pointed out the importance of maintaining a high average in the length of the lives of the inhabitants, and showed that there was great necessity for the establishment of an infectious hospital in the town. He proved that very injurious effects were produced by polluted soil, inasmuch as currencies of air forced through it by ordinary physical laws passed into the houses erected upon or near it, and spread disease amongst the dwellers therein. Then he spoke of the connection between ground water and fever, and expressed a hope that the Town Council would make an investigation into these matters, which were so important to the health of the people. Discussion was afterwards invited, and the meeting thoroughly agreed that an infectious hospital was needed in the town. A vote of thanks to the lecturer concluded the proceedings.

### A Memorial to the Inventor of Ovariectomy.

It is contemplated to erect a memorial statue in honour of Dr. Ephraim McDowell, of Kentucky, the founder of

**Ovariectomy.** The idea having originated in Danville, where the first operation was performed, was earnestly endorsed by the American Medical Association, at its last meeting in Detroit.

The appeal, issued by a number of the leading surgeons of the United States, declares that ovariectomy has outlived all opposition, and through the record of its success has, by common consent, attained a position in legitimate surgery. Nations formerly arrayed against it are now claiming for themselves the honour of privacy. This honour belongs to America.

In the origination and development of new ideas, the pioneer has often to suffer odium and abuse, and rarely lives to enjoy the fruition of a great discovery. This was peculiarly the case with McDowell.

A modest, unassuming man, of large intellect, rare judgment, strong convictions of duty, and possessing a proper ambition to advance the science of his profession and meet the claims of humanity, he accomplished an act in 1809 in the western wilds of Kentucky, which was not only discredited but denounced by the whole medical world. With a consciousness of right, unsupported and lone, and in defiance of professional obloquy, he performed operation after operation with astonishing success, and snatched from the grave the victims of a disease until then acknowledged to be incurable.

Standing firm, encouraged by results, this undaunted surgeon never faltered, although he had not as yet the prestige of a reputation, nor the approving counsel of a single noted surgeon.

America should not stand alone in this work of love and duty. Every country on the face of the earth is equally the recipient of the blessings of this discovery, and is under a moral obligation to send offerings for McDowell's shrine.

This appeal, therefore, for aid, is first made to the women of the world who have been rescued by ovariectomy; next to the members of the medical profession, whose resources have been so greatly increased; lastly, to all who appreciate this advance in surgery, and regard Ephraim McDowell, the Father of Ovariectomy, as worthy of the gratitude of all the human race.

All contributions to the Memorial Fund should be sent to Dr. James M. Keller, No. 58 Green Street, Louisville, Kentucky, who has been appointed Secretary and Treasurer by the committee.

The appeal is signed, amongst others, by Drs. Atlee, of Philadelphia, J. Marion Sims, Peaslee, T. Gaillard Thomas, T. Addis Emmett, of New York, Gross, of Philadelphia, and Parvin, of Indiana.

### Royal College of Physicians.

THE forthcoming Gulstonian Lectures are to be delivered by Dr. Robert Lee, the Croonian by Dr. Greenhow, and the Lumleian by Dr. Lionel Beale.

The Registrar read to the meeting on the 29th ult. a communication from the Registrar-General, relative to the new statute in regard to certificates of death, which will come into operation in January, 1875. It was stated that since the Registration Act has been in operation, in only 5 or 6 per cent. of cases have the causes of fatal diseases been uncertified by qualified persons. The Registrar-General asked for the aid of the College in perfecting the

form of certificate about to be issued, and for any suggestions the College might think desirable to make relative to the names of diseases and other points. A discussion took place on the question of payment of practitioners for the trouble of certifying the cause of death.

### Scarlet Fever.

Now that scarlet fever is spreading so rapidly in the metropolis, medical officers of health and their officers cannot be too cautious in their inquiries as to its dissemination. Ignorance is often the cause of the increase of this dreadful scourge; and in many instances medical aid is not asked for until it is too late. This disease is sometimes treated by the parents of children as sore-throat and rash, caused by cold, and even when desquamation of the skin occurs, no notice is taken of it; and if the case be a slight one, and the child providentially recovers, it is permitted, after a few days' confinement to the house, to mingle with its playmates in the streets, or perhaps sent to school. This last danger cannot be too carefully guarded against. Some notes of what is being done, and of the extent of the epidemic, may be added. We find that the mortality in London of the last week as yet returned amounted to 1,368 deaths, including 1 from small-pox, 8 from measles, 128 from scarlet fever, 4 from diphtheria, 12 from whooping-cough, 43 from different forms of fever, and 21 from diarrhoea. Scarlet fever, which in the previous week's returns showed signs of diminishing, is evidently increasing, the number of deaths registered from the disease exceeding that of any week since the end of 1870. It was most fatally prevalent in Hackney, Clerkenwell, Mile End Old Town, Bow, Poplar, and Brixton. Dr. Dudfield, medical officer of health for Kensington, in reporting to the vestry of the parish on the prevalence of scarlet fever in the district, hints that the School Board of London might, by the adoption of a rule that no convalescent should be readmitted into a school until all danger of infection was at an end, and by prohibiting the attendance at school of children from infected houses, be instrumental in limiting the progress of the present epidemic. Any action taken by the School Board in this direction would probably be widely followed by managers of private institutions. The Paddington Board of Guardians, in consequence of a patient suffering from scarlatina having been brought to the dispensary after being attended only three days at home, have given directions for posting the annexed notice in the dispensary waiting-room:—"Persons suffering with, or recently recovered from, scarlet fever, are on no account to be brought to the dispensary, as such a practice is attended with great danger to the patient, and is sure to spread the disease. The medical officers will attend such cases at their own homes." Dr. Stevenson, in his report of the health of St. Pancras for the five weeks ending October 3rd, shows that the death-rate during the period was only 15.8 per thousand annually—a figure considerably below the metropolitan average; but scarlet fever caused 52 per cent. of the total mortality. The disease would appear to be increasing in the parish. In accordance with the recommendation of Dr. Stephenson, the Vestry have issued circulars to managers and teachers in schools, ministers, district visitors, &c., calling their attention to the imperative need of isolating all cases of scarlet fever,

and of preventing the intercourse of infected with healthy children. The returns from the fever asylums show that there is no diminution of zymotic disease in London. In the south and south-west districts the number of cases is increasing. At Homerton Hospital there were 211 fever patients, 110 of whom suffered from scarlet fever, 71 from typhoid, and 30 from typhus. There are 34 cases of scarlet fever in the small-pox wards. At Stockwell there are 90 cases of scarlet fever, 30 of typhoid, and 16 of typhus.

### A Mechanical Miracle.

THE *Canadian Medical Record* gives a report of a meeting of the American Medical Association, held at Detroit, at which one of the delegates brought before a full meeting a new instrument which he has invented, and which he styles the "Compound Back-action Aurorecto Micro-spectroscopic Speculum." He insisted and attempted to prove that by its use a diagnosis of piles and ulcer of the stomach could be made out. He attempted by a sketch to show the passage of light to the speculum, but he experienced considerable difficulty in making his hearers understand how, in case the colon was impacted, the beam of light could be made to reach the diaphragm. The description and the exhibition of the drawing is said to have caused infinite amusement.

### The Destruction of Young Life in America.

THE *Philadelphia Reporter* alludes to some startling statistics which have been presented at an investigation into the management of the Foundling Farm, near New York. The assistant in charge of the foundling room testified that there were thirty-six babies at the farm two months ago, and there are now three there, all the rest having died.

If the little ones escape the Foundling farms they meet the Mills. There is a law in many States prohibiting the employment of children under ten years of age in factories. But the last labour report of Massachusetts says that there is scarcely a corporation in Fall River which does not violate the law, chiefly at the instigation of parents, who refuse to work unless their children are also employed.

### Pseudo-Charity.

THE London morning papers teem with the announcement of enormous sums given in what they, no doubt, suppose to be charity, by a few individuals in London. Six separate donations of £1,000 each, together with numerous smaller, but still munificent gifts, make up the total contributions to the London hospitals for the month to considerably over £10,000, which brings the month's benevolence in this way nearly to the level of last December, when fourteen separate donations of £1000 were made by one anonymous benefactor. It is a very unwelcome task to say a word in deprecation of generosity so royal, and intentions so beneficent; but, after all, we cannot but entertain a passing doubt that there is anything very wise or very virtuous in this indiscriminate and apparently thoughtless distribution of great wealth, and we very earnestly desire that benefactions so liberal could be placed in the hands of persons who would bring to the

work of distributing it all necessary vigilance, and the most cautious means of inquiry which are available.

There is—Heaven knows—plenty of demand for all the charitable donations which the most wealthy community could spare; but we have to reiterate our great doubts that any considerable portion of these vast sums ever reaches the deserving poor, or goes to alleviate real distress. If any part of it be turned aside from that object it cannot fail to bring evil upon the community, for it serves as an encouragement to adventurers and jobbers who live upon their wits and upon the careless generosity of the public. Apropos, we observe that it is proposed to divert the pitiful balance which remains out of the Hospital Saturday Fund, after payment of the £1,100 of "preliminary expenses," from the object for which it was contributed, to the building of a Sanitarium at Sheerness. Such a job, if carried out, would form a fitting capping to this movement, which, begotten in the vanity of pseudo-philanthropists, has culminated in the public exposure of the unutterable meanness of "the working man."

### Small-pox Inoculation in Ireland.

At the last meeting of the Castlebar guardians the sanitary officer of the Manulla district reported that there were eighteen cases of small-pox altogether in the five townlands around Castlebar; and the officer of the Ballyvary district reported that there were three cases in that neighbourhood. Inoculation, he said, was carried on to a fearful extent in this district, and that with impunity; and he believed that the majority of cases were the result of this nefarious practice.

The clerk was accordingly directed to communicate the complaint to the Local Government Board, informing them that the guardians had taken all possible steps in the matter.

The clerk said the Local Government Board had given directions to the police to make arrests, but nothing had come of it.

The chairman expressed the opinion that those districts in which small-pox existed ought to be put in quarantine; and one of the guardians said that when the foot-and-mouth disease broke out, they put the districts in which it existed under quarantine, and he did not see why they should not do the same in the case of districts affected with small-pox.

### Students' Lecture Examinations.

As one of the results of the recent discussion at the General Medical Council, we are glad to find that a system of fixed examination and instruction has been established at the School of the Royal College of Surgeons in Ireland. Parents can no longer complain that their sons are left without guidance or interest being taken in their progress. Students, on the other hand, who are at all industrious, will find a constant stimulus applied, while, at the end of the session, they will be furnished with a certificate of attendance which will guarantee to the examining body that a certain course of training has been pursued. The examiner will be thus certified that he is examining one who has availed himself of *bona fide* opportunities, while the candidate will with confidence submit himself to the

test. The certificates are not compulsory, but we apprehend will be highly valued.

In conformity with the suggestion made during the past session by the General Medical Council, that certificates of having attended the periodical examinations of the professors in medical schools should be furnished by candidates for diplomas, the authorities of the School have notified to students that during the present session examinations on the subjects lectured on during each week will be held as follows:—On Anatomy and Physiology, each week; and on Surgery, Chemistry, and Practice of Medicine on every alternate week. These examinations will be practical, oral, and written, and each student must put his name on the papers, which will be retained by the professor for reference and examination; and a certificate of having attended these examinations will be given at the close of the session, which the student can present to the examiner or Council in proof of his attendance and information.

### Change of Anatomical Nomenclature.

In a paper read before the Society of Anatomy at Paris, Professor Goubaud urged a change in the nomenclature of human anatomy in reference to the extremities, so as to facilitate the study of comparative anatomy and palæontology. He proposes that the hand should be placed in pronation; that the bones of the carpus in each row should only bear numeric names, proceeding from without inward; that the fingers also should be numbered from without inward; and that for the foot the bones should be classified in the same order.

### Scarlatina in Ireland.

THE Registrar-General's last report shows an apparent decrease in the deaths from scarlatina both in Dublin and Belfast compared with the numbers in the previous week. The deaths in Dublin were 17, being a reduction of 3, and in Belfast 23, being a diminution of 6 in the previous week's mortality.

### The Professorship of Chemistry in Dublin University.

THE Board of Trinity College and the College of Physicians have announced that the Professorship of Chemistry in the School of Physic, hitherto held by Professor Apjohn, became vacant on the 3rd of October, and that on Saturday, the 30th January, 1875, the Provost and Senior Fellows of Trinity College will proceed to elect a Professor of Chemistry.

The emoluments and advantages of the Professorship consist of the following items:—

- 1st. A fixed salary of £400 per annum.
- 2nd. An additional payment of £100 per annum, on condition that the Professor shall give free laboratory instruction to such Senior Sophisters as shall be nominated by the Bursar.
- 3rd. Fees for lectures and laboratory instruction to be regulated from time to time by the Provost and Senior Fellows.
- 4th. The Professor shall have the use of the College laboratory for analyses bearing on medical chemistry,

and approved by the Provost and Senior Fellows, such as medical and medico-legal investigations, and analyses connected with purposes of public health.

### A New Sanitary Difficulty.

DISTRICT registrars now refuse to supply medical officers of health with the weekly returns of births and deaths unless they are paid twopence a case; and the Registrar-General will no longer furnish the necessary information; neither will anyone be permitted to make copies of the Registers at Somerset House, the Registrar's office: consequently, until some one pays the coveted twopence per case, medical officers of health will be unable to give correct returns of the birth and death rate of their respective parishes; neither will sanitary officers have an opportunity of visiting houses in which cases of infectious disease have terminated fatally.

If the claim be a legal one, by all manner of means let it be paid; but the question is, where is the money to come from? If vestries do not think it incumbent on them to pay, on whom will the responsibility rest? But if district registrars will not give medical officers of health all the information they require, surely, for humanity's sake, they could send weekly, if not daily, a list of houses in which deaths from zymotic disease have occurred, in order that the sanitary officer may not be impeded in the execution of his duty, and not suffer death and disease to be sown broadcast in every direction.

### Homœopathic Dosage.

A CORRESPONDENT in the *Medical Times and Gazette* writes as follows:—

SIR,—In the *Monthly "Homœopathic" Review* for July, 1874, is to be found a would-be sarcastic address delivered by Dr. Dudgeon at the late "Homœopathic" Congress, of which he was the President. In this paper, among other interesting facts, we find the following (p. 419):—"One can now practise pure homœopathy within the bosom of the old school without exciting any opposition on the part of old-school colleagues—indeed with the applause of old-school journalists, and without disqualifying oneself for professional chairs and hospital appointments." This must be indeed good news—for some people; but if it is so easy to practise pure homœopathy within the bosom of the old school (which will probably be a fact previously unknown to most of your readers), it seems to be still easier to practise the system of the "old school" within the bosom of "homœopathy," as the following prescriptions by professed homœopaths now lying before me will demonstrate:—

1. Liquor sarzæ 3xij., kali hyd. 3ijss., ft. mist.
2. Kali hyd. 3v., decoctum sarzæ co. (concent.) 3xij., ft. mist.

This "homœopathic" mixture contains, therefore, four drugs! These two prescriptions are by a well-known City "homœopath," who is a member of the British "Homœopathic" Society, and one of its medical officers!

3. Podoph. gr. iij., ext. hyosc. gr. x., ft. pil. xij., to be silvered.

This is by a provincial "homœopath."

4. Podophyll. tinct. gtt. 30, sulph. 200 3ij. A draught to be taken at once.

5. Tartar emetic gr. iss., ignatia (3rd decimal), 3ij., ft. mist.

These last two are by a City "homœopath."

6. A patent medicine called "Ladies' Ointment," for sore nipples, sold at 13½d. per box by a "homœopath" in the North of London.

7. Mercurius solubilis purus gr. xx., opium purum gr. x., bread gr. xx., ft. pil. xlvij. (in syphilis).

8. Hydrarg. biniod. gr. ʒ, pot. iod. gr. ij., ft. pil. i., ter die (in secondary syphilis)

The authors of the last two are members of the British "Homœopathic" Society, and also medical officers of a provincial "homœopathic" dispensary.

The author of the last lately gave three-quarters of a grain of podophyllin for constipation, and nearly finished his patient off.

9. Tinct. opii ʒi., tinct. conii ʒiij., aquæ ʒviiij., ft. lotio.

This is a specimen of "homœopathic" practice in a large provincial town.

10. A few years ago a cupboard full of "allopathic" mixtures was found at a certain public "homœopathic" institution. To the credit of the lay authorities, it was removed; but the physicians who had employed them, and thus practised under false pretences, were allowed to remain.

There are, I believe, in London, some half-dozen *honest* homœopaths who really do conscientiously believe in Hahnemann's doctrines, and endeavour to faithfully carry them out, and there are a few more in the provinces. These of course all can respect as *honest men*, even when they cannot agree with them; but as for those who practise the old system, while calling themselves homœopaths, no one can look upon them without feelings of *disgust and contempt*.

I enclose my card.

I am, &c.,

JUNIUS.

### Contagion in Board Schools.

LONDON is suffering from an eruption of scarlet fever and the authorities are awakening to a sense of the danger of infection from sufferers in their large schools.

We directed attention to this when it was proposed to establish these schools in the various densely populated districts of the metropolis. Those who best know the habits of the poor will most readily appreciate the difficulties which beset the medical and other officers who endeavour to prevent the Board schools becoming centres of infection. The lowest classes herding together in single rooms, and in houses crammed from roof to cellar with families, dread the visit of the officer of health, because he may compel them to seek less crowded abodes, or incur some little expense which they can ill afford; thus they wilfully run increased risk: if sickness attacks any inmate, instead of flying, as their more prudent and richer neighbours would do, leaving the sufferer to the care of members of the family or a hired nurse, the poor assist each other, sit up with the patient night after night, for none know whose turn may be next to suffer, and all dread removal to the work-house, involving, as it often does, the destruction of bedding, the disinfection of the room, and the breaking up of the little home.

It is not until the inmates have decided that there is danger, that the parish doctor is sent for, then, and not till then, can any effective steps be taken to prevent the diffusion of the disease: and where is the *cordon* to be drawn?

The poor widow who sat up last night has gone charring at a villa or house in the neighbourhood, where young children will be exposed to the danger; another has gone home to her little ones, who had to be sent to school, and in the school they become centres of infection, from which it radiates in all directions.

This may be said to be an imaginary danger. Would that it were so! We have had painful experience of the truth and reality of the danger—a family of three young children swept away in one case by fever conveyed in the clothing of a charwoman; another afflicted by the chance visit of the daughter of an old and affectionate servant; a third caught from visiting a poor person in one of these over-crowded houses.

These difficulties appeared sufficient of themselves; but the *Times* of Monday last records a case in which the

enforcement of the compulsory attendance clauses has inflicted a great injury, and if such cases frequently occur, would make the difficulties insuperable. A poor widow was summoned for not having sent her child to school: she pleaded that one of her children, having been removed to the hospital, suffering from scarlet fever, she had kept the others at home. Not being provided with a certificate of the fact, she was sentenced to pay a fine of three shillings, and in default committed to prison.

The doctor has since certified to the truth of the poor woman's statement; the child was removed by his order to the Stockwell Fever Hospital. But what right has any authority to exact such a certificate without paying for it? We have heard of a number of instances similar to this, where a summons has not been issued; and if the poor are to be thus punished for exercising caution, the neglect of which should be penal, the difficulties and dangers of large schools will be so multiplied that their maintenance will be intolerable. In a case that lately came under our notice, the medical officer of health, in despair, endeavoured to teach the schoolmaster to look for certain symptoms; but, after a little effort, that official naturally said the matter was too technical for him.

DR. CAMERON, Professor of Hygiene in the College of Surgeons in Ireland, has in the press a "Manual of Hygiene and Compendium of the Sanitary Laws." This work will contain nearly 400 pages, and embrace chapters on sanitary legislation, duties of sanitary authorities, medical officers of health, and inspectors of nuisances, nature and definitions of sanitary nuisances, sources and quality of waters, and all the cognate subjects.

## Correspondence.

### HOMŒOPATHY AND THE MEDICAL PROFESSION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—“Hard words break no bones;” nevertheless, I am one of those who deplore the unfortunate condition of things which causes professional brethren to spend much of the time and energy which should be devoted to the cure of disease to the infliction of mental wounds one on another.

Can any good come of these criminations and recriminations? While doctors fight patients must suffer.

I would not trespass on your time and space were it not that you ask one or two questions which demand a courteous answer.

You say, “We want to know on what principle a disciple of Hahnemann who professes to believe that a billionth of a grain is necessarily and intrinsically the proper dose feels himself justified in prescribing ten grains, which he *must* believe to be a highly injurious quantity?”

To this the answer is very simple. No physician believing in infinitesimal or a small dose to be the *proper dose* could give a larger dose without grave immorality. But you give no proof that any physician has done so; and I doubt the fact.

If, however, you mean to say that a physician who would treat a case of pneumonia or of pleurisy with minute doses phosphorus or of bryonia must never give a teaspoonful of castor-oil or a dose of Friedrichshaller water to remove an accumulation of fecal matter from the intestines, I fail to see the right-sidedness of the argument.

The same moral obligation which forces a physician to treat certain cases of disease with infinitesimal doses may force him to treat other conditions (which his experience makes him believe to be better treated with larger or material doses) with grains or drops.

To do otherwise would prove him to be an unprincipled sectarian.

It is because the power for cure of infinitesimal agents has been ignored by the majority of the profession that the minority, who have a belief in this power, founded on careful experiment, have been called Homœopaths. But no such physician can, in honour, go further than his experience or his observation of the experience of others leads him.

You next ask, “And we also want to know whether homœopaths who avail themselves of the option,” &c. &c., “do tell their patients, when they choose to prescribe full

doses, that in their particular case they have no faith in billionths, and mean to give full doses?"

■ To this the answer is also simple. The habit is usual in such cases to give the patient a prescription, to be taken to an ordinary chemist, and where such a course is taken the reason is usually explained. In any case, no concealment is attempted; nor would it be possible, as is plain to the simplest understanding, seeing that infinitesimals have no taste, whereas all gross doses of medicines have taste, and most of them have both smell and taste.

These cases are extremely rare in the practice of the physician who has carefully and practically studied the homoeopathic materia medica; but where they do occur, no man truly deserving the name of a physician would for a moment hesitate to do his clear duty to his patient. Were he to be swayed by the taunts of the ignorant, or by any desire to please his patient by other arts than those of cure, he would deserve all that you say of him, and would at the same time act in direct disobedience to the first article in Hahnemann's "Organon," which it would be well to impress on all physicians, viz.—"The physician's high and only mission is to restore the sick to health—to cure, as it is termed."

Were physicians to study the power of infinitesimal agents to cause disease, of which it is possible to give many well-known examples, they would be less ready to deny the curative power of agents of like atomic division; but it is not my intention to enter on this subject in my present letter.

Yours very sincerely,

WILLIAM BAYES, M.D.

58 Brook Street, W., Nov. 5, 1874.

## Medical News.

**Coroner for Central Middlesex.**—The writ for the election of coroner in the room of the late Dr. Lankester has been received by the Sheriff of Middlesex. As the election must take place within fourteen days, the nomination will probably take place on Tuesday next. The constituents are freeholders resident in the district, whether registered or not, having property in any part of the county. There are three medical candidates, Dr. Hardwicke (for twelve years deputy to Dr. Lankester), Mr. Mortimer Granville, and Mr. Diplock; and two lawyers, Mr. Langham and Mr. Boulton.

## NOTICES TO CORRESPONDENTS.

■ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

MR. HILDEBRAND RAMSDEN is thanked.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—By a printer's error only a portion of the Pass-lists of October 29th furnished to us was inserted in our last. The following names of gentlemen (to whom we apologise) should have appeared in continuation of the other lists—October 29th, admitted as Licentiates of the College:—

Alderton, Thomas Gunton, West London Hospital, W.  
Andrews, Samuel, New Southgate, N.  
Byrne, John Joseph, Cheetham, Manchester.  
Edwards, Octavius, Chaxhill Lawn, Gloucester.  
Forty, Daniel Herbert, Guy's Hospital, S.E.  
Hall, Frank Algernon, St. Bartholomew's Hospital, E.C.  
Jalland, Robert, Horncastle.  
Lamb, William Henry, Guy's Hospital, S.E.  
Payne, Henry Peter, Bournemouth.  
Roeckel, Waldemar Joseph, Royal United Hospital, Bath.  
Stephens, Augustus E. R., General Hospital, Cheltenham.  
Tyson, William Joseph, Guy's Hospital, S.E.

The following candidate, having passed in Medicine and Midwifery, will receive the College Licence on his obtaining a qualification in Surgery recognised by this College:—

Hobson, John Morrison, 12 Wynell Road, S.E.

**AN UNNOTICED SOCIAL EVIL.**—A correspondent sends us a letter clipped from one of our leading daily papers with the above heading. He justly expresses his abhorrence that such an indecency should have been admitted into the columns of a paper which has an extensive

family circulation. Our correspondent wrote a mild protest to the editor of the paper in question, but no notice whatever was taken of his letter. We have not space to reproduce the whole of the letter complained of; but if the upholders of "women doctors" seek to enforce their views upon the public in so objectionable a manner, such disgusting effusions cannot but offend those they strive to convert. The following extract will convey a pretty correct idea of the whole:—"We have no hope of the perpetrators of the revolting indecencies and monstrous wrongs of man midwifery. To all who know the vile system, their motives of gain and the gratification of base, carnal impulses are apparent. Reformation can never begin with them, for 'by this craft they have their wealth,' and with that the indulgence of the lust of touch first, and then of that of the eyes. Reformation would most gracefully begin and rapidly prosper if a few ladies of high position would adopt the bold, the true, the Christian course of breaking the trammels of an unholy and polluting modern fashion, by having, and letting it be known, that they had no man midwife to contaminate by his presence their chamber in their hour of trial. But if this may not be, all that is requisite to the utter extirpation of this evil, to the destruction of this moral upas, which has sprung out of, and thriven from the rankness and corruption of modern civilisation, is that the husbands and intending husbands of our time should make themselves acquainted with its nature. Let men but know how tarnished their wives will be if subjected to a treatment which outrages the moral sense and shocks all modesty and decency, and they will, I am sure, take prompt steps to save them from the ruin."

**CHEAP CHARITY.**—Our attention has been called to a printed bill (somewhat resembling the document in which your coal merchant "returns thanks for past favours and hopes to receive the honour of your esteemed orders") in which a Mr. Buller, of the London College of Surgeons, announces that he is open to bidders for his advice at Brent. "In order to show his consideration for the poorer classes," this benevolent gentleman will give his advice for the small charge of 1s. 6d. There is something in such self-sacrifice too divine for the mundane mind, and we confess that, at first sight, we were disposed to imagine that the 1s. 6d. was a very adequate and perhaps much longed-for honorarium.

We have received for publication several announcements of the appointment of Consulting Sanitary Officers under the Public Health (Ireland) Act. As a general rule, the workhouse medical officers throughout Ireland have been elected to the office in their union; but we shall eventually publish a complete list.

**LUNATIC.**—Previous personal experience in the treatment and management of lunatics in an asylum has not hitherto been considered essential qualifications for the appointment of resident medical superintendent, but the tendency appears just now to be to promote assistant-residents when possible, and we heartily approve of such principle. The appointment rests with the Lord-Lieutenant, and "outside influence" has always been the most potent factor in the selection.

**DR. ROSS, Monaghan.**—A description of the best form of disinfecting chambers will be found in the second edition of Mapother's "Lectures on Public Health." The apparatus is, however, expensive and very troublesome in the working. A much cheaper and nearly equally efficient apparatus may be had from an iron-founder, named Fraser, Commercial Road, London, respecting which we hope to have information next week.

## FEES FOR EMIGRATION CERTIFICATES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Permit me to suggest to my country brethren the propriety of charging for the above. No class could better afford to give £5 or £10 than our present class of emigrants. The Medical Association might perhaps lay down an uniform standard.

## A COUNTRY PRACTITIONER.

MR. HENRY MURRAY.—We believe the appointment has already been made, but we have forwarded your letter to the proper quarter.

**WATER-TESTING APPARATUS.**—About four months since a short article appeared in our columns upon a simple method of detecting impurities in water without the aid of much scientific knowledge or previous experience on the subject. Several correspondents during the past few weeks have written to ask us where the apparatus can be obtained. We beg, therefore, to answer them collectively by giving the address of the manufacturers at 157 Strand, London. But the same, we believe, is sold by agents in most large towns. The prices are half-a-guinea and a guinea each.

We are asked by Messrs. Ingram and Co., agents in this country for the Friedrichshall and other mineral waters, to state that communications only will receive attention which are sent to their new address, at 219 and 220 Upper Thames Street, E.C., as their late house at Bucklersbury is closed for City improvements.

OUR INDIAN CORRESPONDENT'S last communication came to hand as we were going to press; it shall appear in our next.

COMMUNICATIONS, Enclosures, &c., have been received from—Dr. Aveling, London. Dr. Van der Smaght, Ceylon. Dr. Hughlings Jackson. Dr. Handzel Griffiths, Dublin. Dr. Hime, Sheffield. Dr. E. Williams, Colchester. Dr. Monckton, Hurstpierpoint. Mr. Giles, Clifton. Dr. Campbell Black, Glasgow. Mr. Blackett, Society for Medical Relief. Mr. Ramsden, London. Dr. Greene, Peckham. Mr. Squire, London. Dr. Douglas, Wymondham. Dr. Boyd Mushet, New Brighton. Mr. H. Moore, Darwen. Mr. W. Berry, Wigan. Dr. Bayes, London. Mr. Southall, Birmingham. Mr. Tallerman, London. Dr. Warner, East London Hospital. Mr. H. Murray, Porteaon. Dr. Boyce, Foxrock. Dr. Kidd, Rathvilly. Dr. Hadden, Wexford. Dr. Kennedy, Tipperary. Dr. Hogan, Ballyvaughan. Dr. Hayes, Naas. Dr. Diamond, Rasharkin. Dr. Stewart, Glaslough. Dr. May, Kilmaganny. Dr. Latham, Ballymoney. Dr. Martin, Blackwatertown. Dr. Hodges, Belfast. Dr. Mahoney, Clonmel. Dr. Brodie, Limerick. Dr. Nevill, Dungannon. Dr. Bales, Kingstown. Dr. Jamieson, Aghnacloy. Dr. French, Glason. Dr. Kiteoon, Nenagh. Dr. Kinkad, Tuam. Dr. Jones, Cork. Dr. Myles, Colehill. Dr. Pollock, Dundalk. Dr. Rountree, Ballincolly. Dr. Hart, Innishofin. Dr. Maguire, Chapelizod. Dr. Parke, Derrygonnelly. Dr. Kidd, Dublin. Sir William Wilde, Dublin. Mr. Mills, Bourne.

#### VACANCIES.

Trinity College, Dublin. Professorship of Chemistry in the School of Physic. Fixed salary, £400 per annum, with other emoluments. (See Advt.)  
East London Hospital for Children, Ratcliff Cross. Resident Medical Officer. Salary, £80, with board, lodgings, &c. Apply for full information to the Secretary. (See Advt.)

#### APPOINTMENTS.

BARK, E. O., L.R.C.P.L., M.R.C.S.E., Resident Medical Officer of the City of London Hospital for Diseases of the Chest, Victoria Park.  
BAXTER, E. B., M.D., Assistant Physician to King's College Hospital.  
COLLES, A. J., F.R.C.S.I., M.B., Medical Officer to the Workhouse and No. 3 District of the Bridgnorth Union, Salop.  
CURNOW, J., M.D., M.R.C.P., Assistant Physician to King's College Hospital.  
DONOVAN, D., jun., M.D., Superintendent Medical Officer of Health for the Skibbereen Rural Sanitary District.  
FALVEY, F. J., L.R.C.P.Ed., Superintendent Medical Officer of Health for the Tralee Urban Sanitary District.  
FENTON, W. F., L.R.C.P.Ed., Superintendent Medical Officer of Health for the Clonheen Rural Sanitary District.  
FINLAY, D. W., M.D., C.M., Resident Obstetric Assistant at the Middlesex Hospital.  
FLEMING, H., M.D., Superintendent Medical Officer of Health for the Omagh Rural Sanitary District.  
GREENE, M., M.D., Sanitary Officer for the Ennis Urban Sanitary District.  
GRIFFIN, L. T., Ext. L.R.C.P.L., Superintendent Medical Officer of Health for the Killarney Rural Sanitary District.  
HORNIBROOKE, W. B., M.D., Superintendent Medical Officer of Health for the Kinsale Rural Sanitary District.  
JEFFERSON, J., L.R.C.P.Ed., Superintendent Medical Officer of Health for the Lisburn Urban Sanitary District.  
LENDON, E. H., M.B., Resident Physician's Assistant at the Middlesex Hospital.  
LYSTER, P. T., L.K.Q.C.P.I., Superintendent Medical Officer of Health for the Athlone Urban Sanitary District.  
M'IVER, J., M.R.C.S.E., Superintendent Medical Officer of Health for the Ardee Rural Sanitary District.  
M'MANUS, G., L.R.C.P.Ed., Superintendent Medical Officer of Health for the Trim Rural Sanitary District.  
MASSEY, D. C., L.R.C.P.Ed., Superintendent Medical Officer of Health for the Tubercular Rural Sanitary District.  
MOLONY, J., L.R.C.P.Ed., Superintendent Medical Officer of Health for the Ennis Urban Sanitary District.  
MOLONY, J., L.K.Q.C.P.I., Superintendent Medical Officer of Health for the Tulla Rural Sanitary District.  
MOORHEAD, M. J., M.D., Superintendent Medical Officer of Health for the Tullamore Rural Sanitary District.  
MORRISSEY, T. J., M.D., Superintendent Medical Officer of Health for the Tipperary Rural Sanitary District.  
MUNRO, A. C., M.B., Assistant Medical Officer to the Southern Counties Asylum, Dumfries.

for the Tuam Rural Sanitary District.

#### Marriages.

FLOOD—MUIR.—On the 29th ult., at St. John's, Greenock, Alexander Wm. Flood, L.K.Q.C.P.I., R.N., to Jessie Macleod Muir, daughter of Richard Muir, Esq.  
MANN—SHARMAN.—On the 4th inst., at St. Paul's, New Wandsworth, Horace, youngest son of the late George Smith Mann, F.R.C.S., Deputy Inspector-General of Hospitals, Bengal Army, to Adamina Lucy, youngest daughter of Henry Sharmar, of Park Road, Wandsworth Common.  
WILSON—BUCHANAN.—On the 4th inst., at 2 Sandford Place, Glasgow, J. G. Wilson, M.D., F.R.S.E., Glasgow, to Edith Gray, youngest daughter of the Rev. Robert Buchanan, D.D., Glasgow.

#### Deaths.

ANDERSON.—On the 2nd November, at Chiswick, Thos. Anderson, M.D., late Professor of Chemistry in the University of Glasgow, aged 55.  
KYNSEY.—On the 28th October, at Athy, co. Kildare, T. Brett Kynsey, M.D., aged 74.  
M'EVERS.—On the 2nd November, at his temporary residence, Rushbrook, John Francis M'Ever, M.D., of Cork.  
FULLAR.—On the 30th October, Wm. Y. Fullar, L.R.C.S.Ed., of Widness, Lancashire.  
WEST.—On the 1st November, at Cloone, co. Leitrim, Geo. B. West, L.R.C.P.Ed., Staff Surgeon Army.

**EAST LONDON HOSPITAL FOR CHILDREN, and DISPENSARY for WOMEN, Ratcliff Cross, E.**—The office of RESIDENT MEDICAL OFFICER to this Charity is now vacant, and applications are invited for the post. The candidate must be unmarried and a fully-qualified practitioner in Medicine and Surgery. There are 36 beds in the Hospital, and an average attendance of from 100 to 120 out-patients daily. The salary is £60 per annum, with board, lodging, and washing.

Application to be sent to the Secretary at the Hospital on or before Thursday, the 19th inst., at 12 o'clock, who will supply a copy of the rules and any other information required.

ASHTON WARNER, Secretary.

#### TRINITY COLLEGE, DUBLIN.—SCHOOL of PHYSIC IN IRELAND.

Pursuant to the provisions of the School of Physic Act, 40 Geo. III., ch. 84, and Amendment Act, 30 Victoria, ch. 9: Notice is hereby given that the Professorship of Chemistry in the School of Physic became vacant on the 3rd of OCTOBER, 1874; and that on SATURDAY, the 30th JANUARY, 1875, the Provost and Senior Fellows of Trinity College will, at the hour of twelve of the clock (noon), in the Board-room of the said College, proceed to elect a Professor of Chemistry, in the room of Professor James Apjohn, resigned.

The Emoluments and advantages of the Professorship consist of the following items:—

- 1st. A fixed salary of £400 per annum.
- 2nd. An additional payment of £100 per annum, on condition that the Professor shall give free Laboratory instruction to such Senior Sophisters as shall be nominated by the Bursar.
- 3rd. Fees for Lectures and Laboratory Instruction, to be regulated from time to time by the Provost and Senior Fellows.

N. B.—The fees as at present arranged are—  
Medical Lectures (Winter Course) . . . £3 3 0  
Medical Practical Course (Summer) . . . £5 5 0  
Laboratory Course (eight months) . . . £10 10 0

Graduates in Arts, and Students whose names are on the College books, are admitted to the Medical Courses on payment of half the above fees.

4th. The Professor shall have the use of the College Laboratory for analyses bearing on Medical Chemistry, and approved by the Provost and Senior Fellows, such as Medical and Medico-legal investigations, and analyses connected with purposes of Public Health.

All Candidates are required to send their names, with the places of their education, the Universities where they have taken their Medical Degrees, and the places where they have practised, to the Registrar of Trinity College, Dublin, and the Registrar of the King and Queen's College of Physicians in Ireland, on or before Saturday, the 23rd January, 1875.

Candidates wishing for further information are requested to communicate with the Rev. Dr. HAVONTON, Medical Registrar, Trinity College Dublin.

ANDREW S. HART, Registrar, T.C.D.  
J. MAGEE FINNY, Registrar, K. & Q.C.P.

doses, that in their particular case they have no faith in billionths, and mean to give full doses?"

To this the answer is also simple. The habit is usual in such cases to give the patient a prescription, to be taken to an ordinary chemist, and where such a course is taken the reason is usually explained. In any case, no concealment is attempted; nor would it be possible, as is plain to the simplest understanding, seeing that infinitesimals have no taste, whereas all gross doses of medicines have taste, and most of them have both smell and taste.

These cases are extremely rare in the practice of the physician who has carefully and practically studied the homoeopathic materia medica; but where they do occur, no man truly deserving the name of a physician would for a moment

## MALVERN COLLEGE.

This COLLEGE contains TWO DEPARTMENTS - the CLASSICAL and the MODERN. There is also a Preparatory LOWER SCHOOL. There are Boarding Houses within the College Grounds, held by the Head Master and others of his Staff; a Gymnasium, &c.

Board and Tuition under 14, £80; over 14, £90. Non-shareholders pay an extra fee of £6. Special advantages for Sons of Clergymen and Home Boarders.

For further information apply to the Rev. ARTHUR FABER, M.A., Head Master, late Fellow and Tutor of New College, Oxford.

The Examination for Scholarships and Exhibitions on December 22nd and 23rd.

**DISTRICT LUNATIC ASYLUMS, IRELAND.**—The Office of RESIDENT MEDICAL SUPERINTENDENT of the District Lunatic Asylum at Castlebar being now vacant by the transfer of the Resident Medical Superintendent of that Institution to the Ennisceorthy District Lunatic Asylum, candidates for that office are requested to forward their testimonials, with a statement of their peculiar qualifications for the appointment, to the Under-Secretary, Dublin Castle, on or before the 21st NOVEMBER next, in order that the same may be submitted to His Grace the Lord Lieutenant.

Applicants must be duly qualified to practise both in Medicine and Surgery, and registered as such under the Medical Act of 1853. Candidates over 40 years of age are ineligible.

The Candidate who may be selected for the Office in question will have to enter upon his duties forthwith.

Dublin Castle, 31st October, 1874.

## THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H. THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid. An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office,

40 MOLESWORTH STREET, DUBLIN.

W. O'NEILL, Secretary.

## DUBLIN INFIRMARY for DISEASES of the EYE and EAR, Ely Place.

Ophthalmic and Aural Surgeon:

ARCHIBALD HAMILTON JACOB, M.D. Dub., F.R.C.S., Ex-Ophthalmic and Aural Surgeon to the City of Dublin Hospital.

Consulting Physician:

EVORY KENNEDY, M.D. (Hon. Caus.) T.C.D. and Edin., Fellow and Ex-President King and Queen's College of Physicians.

Consulting Surgeon:

GEORGE H. PORTER, F.R.C.S.I.; M.Ch. T.C.D. (Hon. Caus.), Surgeon in Ordinary to Her Majesty the Queen in Ireland; Fellow and Ex-President, R.C.S.I.; Senior Surgeon to the Meath Hospital.

Obstetric Physician:

JOHN CRONYN, M.D., F.R.C.S., Examiner in Midwifery, Roy. Col. Surgeons; Ex-Assistant Physician Rotunda Hospital.

Work, Income, and Expenditure for Twelve Months, ending June 30, 1873.

Annual number of Dispensary patients	...	...	...	...
Number of visits paid by such patients	...	...	...	5,847
Number of patients within the Infirmary	...	...	...	124
Number of operations performed	...	...	...	163
Total gross expenditure per bed per annum	...	...	£27	15 0
Average expenditure per intern patient	...	...	1	10 6

The Infirmary is wholly dependent on private benefactions, and is in debt to the Medical Officer. SUBSCRIPTIONS ARE EARNESTLY REQUESTED

Established 1848.

## PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S., &c. (King's COLL.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

**PRACTICES AND PARTNERSHIPS NOW OPEN** for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

Z 56. In a fashionable watering-place, A MIDDLE-CLASS PRACTICE, with appointments, for TRANSFER. Average income upwards of £800 a year. The expenses of conduct of the business are small, as the whole connection lies within a narrow area, and no carriage is required. The house is centrally situate. Rent, £38.

Z 57. In a pleasant district of the Midland Counties, AN OLD-ESTABLISHED PRACTICE, easily conducted, and yielding £400 a year. Patients are all of a good class and there is excellent society. Midwifery fees £1 1s. to £5 5s. One horse does the work. No assistant required. The house is large and convenient, with extensive garden, green-house, and land, but a smaller residence could be obtained if desired. To a gentleman with means the connection affords pleasant occupation with ample leisure.

Z 55. PARTNERSHIP INTRODUCTION. The PRACTICE yields upwards of £500 a year. Appointments, £150. Patients middle-class. Great scope for increase. About £3 weekly is taken in cash. The connection is in a suburb of a large manufacturing town, and presents a favourable opportunity for a gentleman of limited means to commence practice.

Z 54. PARTNERSHIP in a NON-DISPENSING PRACTICE. Average receipts £800 a year, but the business is capable of immediate increase by the co-operation of a suitable partner. To an active gentleman £500 a year would be guaranteed. The half-share is for disposal.

Z 53. LONDON SUBURBS, N.W. A SMALL PRACTICE, which could be made the basis of a very large connection, is offered for sale, in consequence of the ill-health of the Vendor. The receipts average £250 a year. Midwifery fees, one, two, and three guineas. The house contains ten rooms, with large garden. Rent, fifty guineas. The neighbourhood is improving, and there is great scope for an active practitioner.

Z 52. WEST OF ENGLAND. In a pleasant, well-populated district, near the South Coast, AN EASILY-WORKED PRACTICE, yielding £400 a year. No qualified opposition within four miles. All expenses are very low. The house is large, with garden, stabling, &c. Rent, £20. The vendor retires in consequence of an accident.

Z 51. Within forty miles of London, with direct railway communication, AN OLD-ESTABLISHED PRACTICE, yielding £600 a year. Appointments, £40. The whole connection lies within a narrow compass. Patients good middle-class, and very few bad debts. Introduction as long as desired upon partnership conditions. The house has recently been put into complete repair, is small, but convenient, and in an excellent situation. Premium for a short introduction, a year's purchase, half of which may be left on security.

Z 50. Near a large town, AN INCREASING PRACTICE, yielding upwards of £450 a year, with great scope for an active gentleman. There is a convenient house, with good garden, &c. Rent, £35. Patients middle-class. Terms, one year's purchase, half to be paid down.

## Original Communications.

### THE CURE OF BENT KNEE AND THE IMMEDIATE TREATMENT OF CONTRACTED JOINTS.

By J. MORGAN, M.D., F.R.C.S.I.,

Surgeon to Mercer's Hospital, Professor of Surgical and Descriptive Anatomy to the Royal College of Surgeons, &c.

AMONGST the consequences of injury or disease there are few more distressing than the various deformities of joints, specially where they are of so great an extent as to render the limb of which they form part, not only useless, but absolutely inconvenient. They concern equally the practitioner and the patient: on the one hand, the surgeon who has treated the case and brought it through a severe and protracted ailment, finds that his best efforts have left but imperfect results, and that the limb, except for its freedom from pain and irritation, is not of much more use than during the actively diseased state, while on the other hand, the patient, after that a deal of suffering and risk has been submitted to, finds the joint which caused so much anxiety and distress, is but an incubus, and the limb but a useless appendage, to be so carried about for a lifetime.

Various methods have been applied for their cure. The plan of gradual extension by means of instruments steadily applied, with or without division of the tendon, is familiar, and it is asserted that by the steady and long-continued action of such mechanism, deformities can be overcome. Various have been the means adopted, some so complex and expensive as to be beyond the reach of any but the affluent, and others so tedious and difficult in their action that the disappointed patient gives them up. It is to be remembered also, that the method is applicable chiefly to cases of but recent, and more or less delicate deformities.

On the other hand, forcible extension by instrument or otherwise has been advocated by Dieffenbach and others, where by violent and more or less rapid extension, the

adhesions may be broken down by force, without resorting even to powerful apparatus such as those of Louvrier's, whereby fractures and lacerations were not unfrequently caused. By the application, however, of force necessary to accomplish these ends, such injuries to the nerves and vessels of the limb may result as might cause its death; cicatrices around might be reopened and other accidents occur which the application of mere force might entail. Any one practically acquainted with the difficulty of the construction and application of instruments, and the tediousness of their results, must admit that, could an effectual and ready method be attained of remedying the deformity of a stiff joint which would be comparatively free from danger, incalculable benefit would be conferred on a large class of sufferers, and on many whose daily bread depends on their own exertions and capability. The question stands thus, in fact—

Can a patient who has not walked for years (even as I record, for so long as eleven years) be restored to such a condition as to walk well, and for hours, without a stick or support of any kind, and that, in a few weeks after dealing with the condition of joint?

I believe it can be done safely, quickly, and satisfactorily, by the method of forcible extension, as exemplified in instances I am about detailing.

No doubt, at first sight, the idea seems serious of meddling with a joint which has for long been a "thorn in the flesh" of the patient, months or years even, of where early life may have been spent in contending with the results, tedious and painful as they are, of joint disease, a natural hesitation arises as to reawakening a mischief from which the sufferer has but barely escaped with life, and avoided amputation or excision. It is not to be wondered that differences of opinion should exist as to the question of interference in such cases. Mr. Broadhurst thus expresses his views, in advocating the application of direct extension: "Any tendons which are rigid should be divided; the limb is to be fixed so firmly that all motion is prevented, except that which the operator is about to impart to the limb; the adhesions are then to be instantaneously ruptured." Mr. Tamplin in his lectures, *contra*, remarks: "If you rupture the

adhesions, the probability is you will not improve the condition of the patient." Such statements are no doubt difficult to reconcile on any other grounds than that the remarks were not applied to the same cases or to the same class of cases, or where similar treatment was used, and that a much more intense and marked condition had existed than that usually found. I can, indeed, well conceive that a case requiring such powerful machinery as thus described, would not be at all events the one that would be most eligible to treatment. "A padded metal trough, firmly screwed on to a wooden frame, attached to the seat of a chair, receives the thigh, the leg rests within another, and the two cylinders are joined together at the popliteal region by a wheel and axle, furnished with strong catgut cords, and retained by a ratchet, and thus a power is exercised which will fracture the end of the femur itself, if by any accident true ankylosis should be substituted for fibrous adhesions."

The method of forcible extension which I have found successful has proved itself particularly so where a combination of tenotomy and forcible extension is used; (a) in some instances, however, the use of the tenotome may not be absolutely required: this will depend, for instance, on—

#### a. THE SIZE AND STRENGTH OF THE JOINT.

Obviously in a small joint, as for instance at the elbow, we may obtain much more results without division of the tendon, or of myotomy, than we could in the larger one of the knee. Such a joint as the elbow presents also advantages for grasping and for the adduction and abduction of the limb to break down any adhesions, as seen in the drawing, where the left hand is supposed to be placed between the elbow and a table, with the thumb pressed on the most painful point, and the right hand making the necessary motions of extension and of ad or ab-duction.

FIG. 1.

#### b. THE RESISTANCE THAT IS FOUND OUTSIDE THE JOINT CAPSULE (HOOD).

This will concern the hip and knee especially. It does not follow, as in the knee-joint, for instance, that a tendon is necessarily engaged; it may be one or other, or both the inner and outer hamstrings that will require division.

#### c. THE AGE OF THE PATIENT.

While we may, by brute force, and without much difficulty, tear or stretch the muscles of the young, owing to their small size, yet it is found practically that they bear this badly, they retract again directly, and less can be done in the young without tenotomy than in those more advanced in life.

(a) See Broadhurst, Barwell, Gross, &c. Croly, *MEDICAL PRESS*, 1872, p. 93.

#### d. THE ANGLE OF DEFORMITY.

The greater the arc that has to be described by the limb, the greater will be the advantage of "tenotomy" or "fasciotomy," if I may use the word as applying to contracted fascia or cicatricial tissues. In such cases, for instance, where the toes or half the foot rests on the ground, tenotomy will hardly be required, force alone sufficing; whereas in others, where the foot is ten or eleven inches from the ground, and the knee bent nearly to a right angle, tenotomy will be found advantageous, or even absolutely necessary. The instances where I have found the application of forced extension so successful are those of contracted joints, and of the knee notably most so; where previous inflammation had existed, and where suppuration even had ensued, or where the usual protracted suffering from "white swelling" and its consequences, confinement to bed, and a long drain on the system from suppuration has been experienced, and where the patient has recovered with a joint deformed to a greater or lesser degree. A certain amount of motion may be left, flexion may be possible, but not extension. The leg may be absolutely inconvenient from being in the way when sitting or lying, and must become daily more meagre and wasted from disuse and imperfect circulation.

The following very interesting case in the daughter of a gentleman in my own neighbourhood will afford an average and marked illustration of the class of case most suitable and most successful to deal with, at the same time being the most pitiable to leave unrelieved.

An unusually intelligent little girl, Miss E—, now aged ten years, suffered at the very early age of two years from the symptoms of white swelling of the knee-joint, which, after prolonged suffering and risk, left the joint contracted, and as shown in its angular position.

For nearly the last seven years, though various instruments were applied and tried from time to time, the limb has been useless, and for two years past she has absolutely used but one leg only, and consequently she was cut off from many of the joys and amusements of childhood, and suffered considerably in health from want of open-air exercise.

The child presented the following appearance and deformity:—

FIG. 2.

Case of Miss E., showing the position of the contracted knee on August 20, 1874.

On August 20, 1874, I put her under the influence of ether, and divided the tendon of the biceps with the tenotome from behind forwards, using caution to avoid the nerve, and then covered over the wound with plaster I made forcible extension, with the aid of an assistant

making traction at the leg, while I grasped steadily and forcibly the knee-joint all around, making even and tolerably powerful extension at the same time, the adhesions within the joint were felt distinctly to give way, and the limb was at once straightened. It was then laid in a splint well padded and prepared with an extending screw. Everything was made comfortable, the knee wrapped in wadding, and bandaging was methodically applied from the foot upwards. An opiate was given in the evening, and the child kept her bed for about two weeks, and during this period she had not a troublesome symptom of any kind. She was out walking and playing about, and even took a long walk within a month, of nearly half way round Howth within two months after the extension of a limb which had not been used for so many years. She uses no stick of any kind, but simply

FIG. 3.

Case of Miss E., showing the perfect position of the limb on October 5, 1874, after extension.

a band across the patella attached to lateral iron rods, and she can go up or down stairs two steps at a time. As may be expected, nothing can exceed the gratification of both the parents and the child at the comfort obtained and the ease with which she walks, a very slight halt being alone perceptible. The appearance represented in the illustration was drawn by Mr. Oldham in the first week of October, and shows the straightness of the limb, in remarkable contrast to the deformed condition of August 20th.

Having given the general details of this case, it will serve as a guide for the application of the combined treatment of tenotomy and forcible extension.

The point which presents itself for consideration is—What would influence us in interfering with such a joint with a hope of obtaining a good result?—a question indeed of no inconsiderable gravity.

In this case no sequestra had ever escaped from the joint. There was no evidence either of there having been at any stage of the disease an abnormal lateral or unnatural movement of the joint, and it had always retained the hinge or ginglymoid movements.

On examination it was found that the extremities of the bones were not knit together; a certain amount of flexion remained and also extension till "pulled up" by the offending tendon and adhesions, all arguing that bony ankylosis had not occurred.

The patient was able to bear her weight fully on the limb when put in the position for doing so.

The disease originated apparently in an injury, and ran a rather acute course in the beginning, all auguring that limited adhesions only had formed inside the joint.

Of course, the longer the deformity existed the more

firm would be adhesions, while the angle of flexure would be constantly diminishing, and I need hardly add that the suffering from want of air and exercise, and the limitation of enjoyments and of prospects, were also important considerations in determining on making an effort to relieve the joint. Had the deformity been merely one allowing of locomotion, there might have been some hesitation, but it required an extraordinary effort and position even to touch the foot to the ground. As Mr. Barwell puts it, "The use of considerable force is justifiable for the reduction of a malposture of the knee-joint, but unjustifiable in the re-establishment of mobility in a joint already in good position." Many are timid about interfering with such a joint, but it is to be remembered that the previous processes of inflammation and degeneration, as indicated often by the suppurative and long existing sinuses, have more or less destroyed the synovial structure; and just as an eye which has been the subject of disease bears interference so much better than a healthy one, so an abnormal joint, where immediate inflammatory action has passed off, will do likewise. A consideration of the steps I adopted in this case will best serve as a guide for the practice of this method of cure.

Ether was administered, because it is the safest, according to statistics; while the results are as good or better, as an American writer has unpleasantly put the case, that a practitioner should be punished if his patient should die under ether, as he can prevent it—whereas with chloroform, accidental deaths, or deaths from idiosyncrasy so-called, or in other words, inexplicable deaths will occur, and do occur pretty frequently.

Tenotomy was used with the sharp-pointed tenotome cutting towards the skin, but it may be done equally with a blunt-pointed one after a preliminary incision has been made at some distance in the skin. Marked alteration in the extensibility of the joint immediately ensued; I at once closed the wound over with plaster, and proceeded with the extension. The external wound being so small, and the tenotomy being made subcutaneously at a distance from it, I can hardly estimate as a danger that air would, as has been surmised, be sucked in at that point; at all events I have never seen it, or any other inconvenience. Of course, in dividing the biceps tendon, care should be taken to avoid the nerve, which can be done by pushing in the point of the finger well, and separating the tendon and nerve, and keeping on the inner edge of the tendon. There is practically no danger where discretion is used. Some prefer making the tenotomy a few days before the application of extension, and then letting the external wound heal first, and Mr. Barwell mentions a case where the inner and outer hamstrings were both recently divided, and where, when extension was applied, the skin was split from one to the other; it is difficult to conceive this accident from so small an incision as that of a tenotome, but as it is recorded, its possibility should be borne in mind. Having closed the wound over, I got an assistant to lay hold of the leg and make steady traction, more by the dead weight of the body than absolutely by pulling. I grasped round the joint with my hands, keeping the fingers of one hand well in the popliteal space to support the head of the tibia, fearing

FIG. 4.

Mode of manipulation for the extension of Bent Knee.

it might possibly slip backwards. I myself assisted actively in the extension, and I felt plainly the "crack, crack" of the adhesions giving way, and in a minute or two the limb was straight. As it is important, I think, that the surgeon should pull forward on the back of the head of the tibia, I append an outline of the position of the hands *in situ*.

In other instances, where greater force is required, it is well even to put the forearm near the elbow, under the knee, and thus pull forward the head of the tibia, while powerful extension would be made, and so avoid the possibility of a dislocation.

Fig. 5.

Mode of using the arm in the extension of Bent Knee.

(To be continued.)

#### CASE OF CROUP.

Under the care of JOHN LEONARD KEALY, L.R.C.S.I.,  
L.R.C.P.E.

Medical Officer St. Peter's E. WarJ, Dispensary District Drogheda.

On the 2nd November my friend, Dr. George Delahoyde, of Drogheda, in my absence from town, saw for me a child, aged three years, whom he found on examination to be suffering from croup. He prescribed emetics, and at the same time ordered beef-tea and other appropriate nourishment. On the following morning I saw the case, and expressed my opinion that the little patient had very slender chances indeed of recovery. I ordered the nourishment to be continued, and increased the emetic dose, promising to interfere surgically if the remedies given would not have a beneficial effect. Strange to say, the mother offered no objection to the proposed operation, but, on the contrary, asked me to do anything that I thought might give my patient a chance. Dr. Clarke, of Drogheda, and his father, Dr. Clarke, of Armagh (who has retired from practice), kindly gave me their advice on the case, in consultation with Dr. Delahoyde. These gentlemen believed there were very slender hopes that anything I could do would save my patient, but agreed, as the little fellow was fast sinking, it would be good surgery to operate as a *dernier ressort*.

Accordingly, with the very able assistance of my friends, I performed the operation of tracheotomy in the usual way. Owing to the great dyspnoea and consequent venous engorgement, there was some hæmorrhage, which, however, by pressure and cold applications, was easily controlled. Most surgeons recommend at this stage of the operation to wait until the hæmorrhage has completely ceased before the trachea is opened; but Collis points out that there is no necessity to do this, as pressure with wet lint is, in the majority of cases, sufficient to prevent blood getting into the tracheal wound; besides, the length of time you might have to wait would render the operation futile. The usual incision having been made into the trachea, and the tube being properly secured, manifest relief was experienced by the patient. Stimulants were freely given, and we had hopes that our interference might save life.

However, after a short time, it became evident that our patient, though relieved for a time, would die from asphyxia, which occurred in less than one hour after the operation had been completed.

I beg to bring this case under notice for two reasons:—

1. To urge on practitioners, when croup has been once fairly established, to lose no time in operating, as it is my conviction, had I interfered earlier in the case I am relating, and not have trusted to the emetic plan of treatment, the result in all probability would have been far different from what it was. M. Bretonneau, of Tours (if I remember rightly), operated very easily in croup, and with extraordinary success.

2. That even very young surgeons should have no hesitation in using the knife in such cases, as, to one acquainted with the anatomy of the parts, tracheotomy presents no unusual difficulty. Magnifying the danger of operations is, in my opinion, much to be deprecated, as it tends to discourage younger hands from interference surgically when such interference is necessary.

#### SUCCESSFUL CASE OF LIGATURE OF CAROTID ARTERY.

By R. H. SUPPLE, M.B., &c.,  
Medical Officer Collon Dispensary.

I WAS attending Mary C—, aged about 23, for sore throat of a severe form, accompanied by great fœtor and deep ulceration. She did well up to the 21st September, when, on my visit at 11 a.m., I found her sister very much alarmed about her, as she had bled a good deal out of the mouth during the early part of the morning, but it had stopped as suddenly as it began. I made a careful examination of the throat, but could not detect where the hæmorrhage had come from. I told them, should it recur, to send for me immediately. I had scarcely got out of the room when her sister ran after me to say that she was dying. I returned without delay, and found the poor girl bleeding frightfully. I instantly looked down the throat, and saw that an ulcer had eaten through the coats of a large artery. I directly put a pencil of argenti nit. into it, and sent for perchl. ferri and other styptics, all of which I tried in vain—they merely lessened the hæmorrhage for a time; I also made digital pressure on the carotid. By these means I kept my patient alive until Dr. Kealy, of Drogheda, arrived, as I had sent for him to assist me to tie the carotid artery, as the only means of saving the girl's life. When Dr. Kealy saw the case he quite concurred with me about the propriety of the operation I had decided on. We got the bed our patient was in lifted to the window, as the room was dark, and she was too weak to move to another. I then made an incision about three inches long upon the anterior edge of the sterno-mastoid, and exposed the sheath of the vessels without much difficulty; some branches of the descendens noni nerve gave a good deal of trouble; the jugular vein was quite empty and was easily drawn to one side by the finger. I now easily passed an aneurism-needle armed with a strong silk ligature from without inwards round the artery, and, having tied it, cut off one end close to the vessel and left the other hanging out of the wound, which was closed by two sutures, and a pad of lint fastened by plaster completed the operation. There was not a drop of hæmorrhage from the moment the artery was tied, nor was there more than half-an-ounce of blood lost during the entire operation. The case progressed most favourably from this, the ligature came away in the dressings on the seventeenth day, and in a week more she was able to go away for change, as I thought it advisable, owing to her delicate state. She has just returned in excellent health.

I cannot conclude without expressing my gratitude to Dr. Kealy for the able assistance he rendered me in so difficult and trying an operation.

## INTRODUCTORY ADDRESS

DELIVERED IN THE

THEATRE OF THE RICHMOND HOSPITAL, DUBLIN.

By W. THOMSON, M.D., F.R.C.S.I.,

Surgeon to the Hospital.

Mr. Thompson, after a few opening remarks, said he had selected for his subject Medical Education, preliminary and professional, and in the course of his address said:—

The question of medical education has been somewhat prominently brought before us this year by the proceedings of the General Medical Council. This body, as you know, is constituted by Act of Parliament, and is composed of distinguished representatives of the different branches of the profession in the three kingdoms. With these lie the control and direction of the education of our students. Very recently they have sent commissioners to various examinations throughout the country, for the purpose of reporting upon their efficiency as tests of the candidates' technical knowledge. These gentlemen, I may say, have not reported favourably of very many. The judgments in some cases have been rather adverse, and it has been generally admitted that some changes were necessary. Yet I think I express a very wide-spread feeling when I say that, in the course of the discussion upon these reports, observations were made by certain members regarding Irish examinations which were tinged with an undeserved severity, while other bodies in England and Scotland, very distinguished for their deficiencies, had attention diverted from them almost totally. This is not the place to make more than a passing allusion to the Report of the Commissioners. The observations and suggestions submitted, however, will doubtless lead to changes which cannot fail to be of interest to you. What these will be it is not possible very definitely to say; but this much appears certain, that in the future, examinations will become increasingly practical, and that no mere book-knowledge will satisfy the court as to the pupil's proficiency. It will not be possible for a man to become a surgeon whose sole grasp of anatomy consists in his acquaintance with some handbook, or who can give eloquent descriptions of cases in the hall which he is utterly unable to recognise in the hospital. The practical spirit which exists round about us has also become diffused through our own profession, and it is right that I should warn you to adopt it, and to be prepared for its developments. Taking up my subject in its natural order, I wish to speak a very few sentences with regard to preliminary education. I do so with some diffidence; but whatever opinions I hold, they have been long forming, and are not the produce of any new-born zeal. It seems to me that a great mistake is too often committed in the insufficient preparatory training of our students. I do not blame parents for this; they are anxious to have their sons start early in life, and they naturally believe that in fulfilling the requirements of the law they have done all that is necessary. The body at fault appears to be the General Medical Council—not the Government, not the public, not any particular institution. The Council prescribes the examinations which every young student must pass in order to be duly registered. But it is not a little startling to know that it recognises some fifty different tests, all dissimilar in difficulty and extent, ranging from the most severe to the most simple. Nor are we reassured by examining the slender basis upon which the pupil is expected to rear a superstructure of knowledge involving the most intricate and subtle considerations. We have heard a great deal about conjoint schemes and the raising of the standard of professional examination. We are assured of the great advantages which the "single portal" mode of admission to the profession possesses, and under certain conditions I believe in them. But have not the Medical Council and the advocates of these changes commenced at the wrong end? Are they not falling into the error of demanding a uniformity of result

without trying to secure any uniformity of preparation? One other mistake lying at the root of this question is the early age at which the student may enter upon his work. If professional study were only to count from, say 17, or later, ample time would be afforded him to engage the mind in something more intellectually strengthening than that which forms the course of instruction in the great majority of schools. If he is able to take a full arts curriculum in a university, so much the better; but I believe that he should be at least required to undergo an examination equivalent to what is known as the "little-go," as a test of his educational status. Besides subjects which are obviously necessary, there should be a fair knowledge of a foreign modern language and of the literature of his own, of the elements of logic, with some of the higher mathematics, and experimental physics. I am quite aware that a great many of our students do possess knowledge much in advance of this, and, on the other hand, that those who have never gone through any such course pass high examinations in technical subjects. But what I wish to be understood as pressing is this, that he who had pursued it would prove a more appreciative student, and rational and probably successful physician or surgeon, than he who had contented himself with satisfying the test of the General Council. To my mind, it is a positive injury to the student to receive him on such terms: he is deprived—because he is as yet unable to exercise judgment in the matter—of the pleasures which are to be found in an acquaintance with general literature and philosophy; his mind has never undergone any of the strengthening discipline resulting from a practice of the simplest rules of logic; and before he has learned anything of the laws of thought, or been able to arrive at any mental breadth or depth, he is plunged into the midst of professional study. With great respect, I do not believe in the wisdom which makes such a thing possible. The requirements for admission should, if anything, be superior to those demanded for law or divinity, in neither of which, as a profession, is there the great variety of study or the multiplicity of subjects with which every medical man must make himself acquainted. But, independent of the utility of general culture for purposes of the profession itself, there is another consideration which would render it desirable. It is a well-founded observation that there is a tendency in devotion to any one particular line of study to force the mind into a narrow groove; it becomes impregnated with law or medicine as the case may be; and if it be not now and then watered with the gentle dews of "deep philosophy, wit, eloquence, and poesy," it will soon become like a desert, parched and unbeautiful. Moreover, I think there is in it for the student a safeguard which ought not to be neglected. Separated from home, without friends perhaps in the city to take any special interest in him, the student seeks relaxation for his wearied brain. For many it may be found in turning to lighter reading, and renewing the acquaintance with old familiar words; but some search for it in places which are certainly not conducive to increased knowledge of their profession. I am an advocate of recreation provided it be sensible and pure; but in a large city like this there are attractions which ought only to be known to be shunned, and which have brought to those who set out with fairest prospects misery and disaster. A recourse to literature is a pastime which would save them from a temptation to ignoble pursuits, and afford them much profit, serving to make wider and firmer the basis of their knowledge, and to raise their office to a higher dignity by their general intelligence and by the nobility of their conduct.

Mr. Thomson then proceeded to speak at some length upon professional education, impressing upon his hearers the need of a careful study of anatomy, physiology, histology, pathology, &c. He urged the importance of hospital work and of note-taking, and, while condemning the idlers, defended the class of medical students from the charges of people who were themselves little accustomed to disinterested self-sacrifice, and who were for the most

part content with a passive and frequently selfish existence.

After a brief sketch of the more important recent advances in surgery, he said: These are great achievements, but they are not by any means all, and in the future we may expect that enthusiasm, well directed, will lead to victories more brilliant still. The whole field of science is open wherein to exercise your highest faculties. It is true that at no period have the workers been so many; but do not fear that there is no room for your exertion. What has been discovered seems to be but upon the borderland. There is a vast unknown country beyond, full of buried truths, with crowds of eager explorers, crying, like Goethe, for "more light," ever pressing upon it. It may be that that truth of which you are in search lies deep down amid much grosser stuff, and will take much time and patience to bring to the light of day; or it may be but lightly covered, to be turned over by the foot of some heedless dreamer. But do not depend upon such chance discovery. They who have been most successful, who have done the greatest good, and have left behind an enduring name, are the men who, with sweat of brain as well as sweat of brow, have toiled through many years in unflinching hope of reaching the goal at last. Strive, therefore, resolutely but reverently, to widen still further the bounds of scientific knowledge. Endeavouring thus to stimulate you into real work, I may be permitted to remind you that, as students of the School of Dublin Surgery, you have much honour to maintain. We have had in this city men whose names will ever be associated with whatever of glory belongs to our profession—Crampton, Cusack, Porter, Colles; and in connection with this old Richmond Hospital—as renowned as venerable—Carmichael, Todd, Peile, McDowel, Hutton, and the illustrious teacher of many of us, Robert W. Smith; and one more—we have the distinguished Father of Surgery in this country—Robert Adams—of whom it is the highest praise to say that, recognising the magnitude and responsibility of his work, he has done and continues to do that work well and nobly. These and others whose names will occur to you have given us a heritage of fame which it is our duty jealously to guard. Let them be exemplars in ceaseless activity, in unflinching perseverance, and in fidelity to principle. As with them, disappointment and defeat will meet us often; but even from these we shall gain something if they help to nerve our falling hands and to give new vigour and determination to our effort. And when at last it shall come to you and me to cease from our labour, may we find some solace in the consciousness that "in hearts we leave behind" there will abide for us a tender memory of an useful life and an honourable name.

Mr. Thomson concluded amid loud applause.

The Chairman (Mr. John Hamilton) announced that the clinical prize had been awarded to Mr. Effingham McDowel.

## INDIAN MEDICAL NOTES.—No. XXIX.

(FROM OUR SPECIAL CORRESPONDENT.)

MEERUT, October, 1874.

### "PRACTICAL."

ONE dark oppressive night, or rather morning, in September, when the regular work here involved hourly life and death anxiety, the riding-horses, the servants, the natives, all sick, or hard pressed to carry on the current duties, the following note, received in bed, was startling, especially the address, from Sirdhana, 14 miles distant, the latter part of the road three weary, jolting, spring-breaking miles, over a partially ploughed field, along the bank of the canal:—

"Major — went out shooting at 5 a.m. to-day intending to return to lunch, but, interested, and getting good sport, went on without refreshment, excepting cold tea—soon expended; walked 24 miles, took off his helmet to stalk deer, got a slight sunstroke, and fainting, was

restored by means of cold water poured on his head by attendant; but again he became insensible, so remaining some time, finally managing to crawl back 4 miles, resting by the way, retching every few minutes, and in absolute agony with cramps, which seized feet, legs—every part of his body. He failed at the steps up to the house, and when I saw him, at 9 p.m., he was in cold perspiration and torture one moment, fainting away the next. He had been standing a good deal in water, and was wet up to the waist. I gave him brandy, and he got into bed, but brought back the brandy with a rush, and it has been all we can do to rub his legs, with hot bottles, and hold them, for he is in very great pain, violent spasms, his limbs twisting without control. Madly thirsty, he has drunk eight bottles of soda-water, bringing each up instantly. Cold water to his head, mustard applied over the stomach, the feet in mustard and hot water. His eyes are so oddly sunk; and some medicine given him by a native doctor was immediately vomited."

The remainder of the letter contained the usual alarm and cry for help, written by the patient's wife—graphically expressive—the apology for quotation here.

As usual, three courses were open—either to plead fever, to send the note to the civil surgeon, who attends waifs and strays, else, the message being so urgent, every moment of consequence, to go. The latter course adopted; and as the house is perfectly solitary, it was necessary to carry medicines, blisters, catheters, hypodermic syringe, essence of beef—a heap of things, including stimulants. So the pet grey flea-bitten Arab and dog-cart (a splendid bargain for £50, the property lately of a consumptive captain) had to be trotted out. That clever novel, "The True Reformer," opens at Sirdhana, where the Begum Somroo lived and built a church, besides endowing schools for the transformation of native children into French Roman Catholics. "The True Reformer" received a different note, conveying the news of inherited wealth, whilst pig-sticking in the district. Besides two tapering towers and a pleasant peal of bells, the church boasts of the Begum's tomb, a fantastic jumble of fairly executed figures in monumental marble, the old lady uppermost. When her disorganised troops were short of pay, they placed their commanding officer, denuded of his trousers, astride a heated gun. Amongst the squalid natives in the dirty bazaar has lived alone, for many years, an English lady, now grey-headed, with a painful history, better untold. The general effect of Sirdhana—harshly discordant—about as harmonious as a Hindoo temple and priests would be in a quiet peaceful village, such as Friern Barnet, where clever Dr. Anstie rests. At the present moment the sound of firing over a poor fellow's grave, a quiet simple Christian, recalls to mind the words "Blessed are the dead, for they rest from their labours."

The scorching sun glared maliciously down as the distressed over-driven little horse, covered with foam, panted through the substantial gates of the lodge, along the shady avenue, through the graceful sweet-smelling orange-groves leading to the Begum's palace, a fine-looking house, generally empty, occasionally occupied by convalescents, or some traveller favoured by Mr. Billings, who worthily represents the absent owner, the Hon. Mrs. Forrester.

The patient, very much better, had almost shaken off the attack. Aged 42; off and on in India since 1852; had endured fever, ague, rheumatism, dysentery, besides, in 1854, a mild attack of cholera, attributed to drinking ditch-water, so decided that all but one servant deserted, panic-stricken. Yesterday, when parched with thirst, he drank muddy water out of a dirty village well, possibly influencing the dyspnoea, impending suffocation, retention of urine, vertigo, cramps from feet to knees, the muscles standing out like ropes, the toes turned down, the great toe separate, the arms free; no epileptic history. A gallant, indeed, distinguished soldier, a great smoker, by no means the stamp of man to make much ado about nothing, his case, in my humble opinion,

would have been genuine cholera but for the previous attack. Mere assumption—opinions grounded on vague report though they be—I do not stand alone in the idea promulgated. Malarious Sirdhana contains the usual dirty ponds covered with green vegetation, varied by white, pink, or purple water-lilies, surrounded by banks of slimy mud. In 1866 all the old grain pits became full of water, when persons and animals feeding on the spoilt grain fatally sickened.

(To be continued.)

## Hospital Reports.

### METROPOLITAN FREE HOSPITAL.

(Cases under the care of Dr. CHARLES R. DRYSDALE.)

#### *Dysentery and Ipecacuanha.*

RICHARD LEEDHAM, 34, formerly in the Bombay army, contracted dysentery in Poonah in 1866. He was in hospital for two months with the disease, and was invalided to England in 1871 for this disease and liver disease. There is a scar at the edges of the ribs, at the level of 2nd, below xiphoid cartilage, through which blood and matter issued on board ship returning home. After getting to Netley the dysentery was cured, and he had no more attacks until four months back; but he has had it ever since then. Had perhaps a dozen stools in twenty-four hours, slightly tinged with blood, and often entirely composed of blood and slime.

March 17.—To take five-grain doses of powdered ipecacuanha four times a day.

March 31.—Returns to say he has only four motions a day, in the twenty-four hours; no blood; no straining; tongue white, furred. The medicine does not make him sick now; it did at first. He was soon quite well.

Isabella Jenkins, aged 54, has been a widow for eighteen years. In the year 1863 she had cholera, and was eight weeks in St. Mark's Hospital. She has since that time continually suffered in the abdomen. Had blood in the motions, and also matter. She came to the Metropolitan Hospital in April, 1874, complaining of great relaxation of the bowels. Five grains of ipecacuanha powder were prescribed, to be taken occasionally. The patient came on the 14th April and said she was very much better; she said she could not tell the comfort she had; was better the first powder she took. Motions are now regular—one a day. The last powder made her sick.

### CASHEL UNION HOSPITAL.

(Cases under the care of Dr. LAFFAN.)

By Dr. W. P. HOURIGAN,

Medical Officer Tullaroan Dispensary, formerly Dresser to the Hospital, and subsequently Resident Medical Officer to Mater Misericordiae Hospital.

#### *Fistula in the Neck.*

PATIENT a young man, æt. 28. The track extended from the clavicle between the sternal and clavicular origins of the right sterno-mastoid muscle to within a short distance of the mastoid process of the temporal bone, becoming deeper as it ascended. The affection had lasted for six years, and from the patient's own account appears to have had expended on its treatment most of the resources of legitimate and illegitimate art. Anatomical considerations suggested to Dr. Laffan the prudence of giving a trial to palliative measures, and these were accordingly tried for a period of more than two months, but without perceptible effect. Dr. Laffan then cut the lower half of the fistula open with the knife, and plugged it from the bottom with lint. He reserved the upper half for division by the galvanic cautery, as the safest course to be adopted. The part of the fistula which had been incised

healed up in a few weeks, and some delay having unexpectedly arisen in getting the galvanic apparatus ready, Dr. Laffan found to his great surprise, on examining the patient some weeks subsequently, that the incision already made had been sufficient to cure the entire fistula.

#### *Fistula in the Thigh.*

This happened in a boy, æt. 6. Had existed for some months, and extended from the apex to the base of Scarpa's triangle of the right thigh. Palliative treatment had in this case, as in the former instance, been given a trial, and with the same result. Dr. Laffan then cut open the fistula, and the consequence was equally satisfactory as in the former cases.

## Transactions of Societies.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, OCTOBER 27TH.

Mr. TIMOTHY HOLMES in the Chair.

#### A CASE OF ABDOMINAL ANEURISM OF UNUSUAL SIZE.

By Dr. BAKWELL, of Trinidad.

The patient was a man 38 years old, who had been a soldier for fourteen years, serving part of the time in India, but for the last seven years had followed the occupation of a painter. He had had gonorrhoea and syphilis, but no other illness, and was not of particularly intemperate habits. Four or five months before being seen by Dr. Bakewell he suffered from severe pain in the back and loins, during a voyage from New Zealand; but this soon got better, returning, however, with increased severity on January 1st, 1874, and affecting also the left thigh and knee. When seen on April 24th, he was unable to flex the thigh upon the trunk, and on examination a swelling was found in the left loin, which formed a large smooth fluctuating tumour filling the left lumbar region, and felt also from the front. There was an entire absence of pulsation, and after another examination the diagnosis of lumbar abscess was considered clear. A month later the tumour was found to have undergone an enormous increase in size, and now occupied the whole left side of the abdominal cavity, which was bulged in front and behind; there was visible and expansile pulsation all over the tumour, and fluctuation could also be detected from the back as far forwards as the linea alba. A loud bruit was also audible all over the tumour. The diagnosis of aneurism was now evident, and the swelling rapidly increased; but some one having suggested that it might be a renal cyst, a trocar was inserted at the posterior part, and the canula, from which only blood issued, was left in with its orifice plugged. Three weeks afterwards the canula sloughed out, and the patient died two days later from exhaustion, the pulsation having considerably diminished. After death the left semi-circumference of the abdomen was found to be seven inches larger than the right, and there was a large slough over the posterior part of the tumour. The aneurism was found to occupy the whole left side of the abdominal cavity, from the diaphragm to the iliac fossa, the peritoneum was stretched over it, but not perforated, and the organs displaced and compressed. The interior of the wall of the sac was lined by an irregular layer of laminated fibrinous coagula, which in some parts was of considerable thickness; and the sac contained also a quantity of fluid blood and coagula. There was erosion of some of the upper lumbar and lower dorsal vertebrae. The sac of the aneurism communicated with the aorta by an oval orifice opposite the eleventh and twelfth dorsal vertebrae. The author stated that he had found no record of an aneurism of such size; he expressed his belief that the sac had in the first instance passed between the psoas magnus and quadratus lumborum muscles, and that to their pressure was due the absence of pulsation when first examined; that later, by the giving way of the psoas, the rapid increase occurred, and fluctuation, pulsation, &c., were developed. He considered the cause of the disease doubtful.

# A CASE OF RECOVERY AFTER REMOVAL OF A FOREIGN BODY IMPACTED IN THE FEMALE PELVIS FOR TWENTY MONTHS.

By Mr. BARWELL.

The patient was a young woman who, having reason to fear the occurrence of pregnancy, consulted an abortionist, who, it was supposed, attempted to introduce a gum-elastic catheter into the uterus. The patient, finding it slipping out whilst at the closet, had endeavoured to push it in farther, and it had then disappeared, much to the alarm of the abortion-monger. Two or three months later the patient complained of severe pain in the left hip, thigh, and leg, which was ascribed by the medical attendant to some deep-seated irritation. The pain, however, was relieved, and it was not till twelve months later that any further symptoms were complained of, when a large abscess formed over the left hip; and on inquiry being made, the patient related the history of the gum-elastic catheter. On examination, in addition to the abscess, there was found a sinus in front of the tuber ischii, through which a probe, when introduced, passed up by the side of the rectum, but did not enter the bowel or the abscess. By incision, a large quantity of feculent pus was evacuated from the abscess, but no foreign body found. A few days later, on making a careful examination per vaginam, a hard transverse ridge was found at the upper and posterior part of the vagina; and by rectal examination a corresponding ridge was discovered, and a part of it was found to be due to some foreign body lying in a pouch communicating with the rectum. By the aid of the finger and polypus forceps this was got hold of and drawn out, and was found to be the catheter, which had lain transversely, and in a curve corresponding with that of the brim of the pelvis. The patient recovered without any unfavourable symptoms. The explanation of the case given by the author was that the catheter had been passed into the cervix uteri and through its posterior wall, and by a careless removal of the stilette it had been forced still further. Pelvic cellulitis and perimetritis were set up, and had given rise to the abscesses in the hips and buttock.

# A SUCCESSFUL OPERATION FOR THE REMOVAL OF A LARGE FIBRO-MYOMA FROM THE FUNDUS UTERI.

By Mr. LAWSON TAIT, of Birmingham.

The patient, whose age was 34, had suffered from a large abdominal tumour of rather rapid growth for five years. There was profuse menstruation, and frequent symptoms of pressure on the pelvic organs. The tumour was central, and reached two inches above the umbilicus; was completely solid, and movable with the uterus. It was removed by an operation on January 16th, the steps of the operation being exactly the same as for ovariectomy. The tumour was found to spring from the whole of the fundus uteri, and the part of that organ above the internal os was removed with it. Recovery was rapid and uninterrupted, and the clamp came away on the eighth day. The tumour weighed eleven pounds, and was an ordinary fibro-myoma.

# MEDICAL SOCIETY OF LONDON.

MONDAY, OCTOBER 26TH.

Mr. VICTOR DE MERIC, F.R.C.S., in the Chair.

Mr. FRANCIS MASON exhibited a patient, aged 19, who had been under his observation for about five weeks, with a well-marked infecting sore on the upper part of the thigh situated over the great trochanter. The patient had a secondary eruption, and there was no other sore on any part of the body to account for it. Mr. Mason brought the case forward because the true nature of such cases was so frequently overlooked.

Mr. MASON also exhibited a child, aged 7 months, who had a congenital deformity of the right hand, which consisted of a palm with two fingers only, and these were webbed. Mr. Mason had placed a silk thread through the proximal end of the web, and this was allowed to remain for three weeks, when the perforation was found to be quite healed. The web was then divided and the wound rapidly cicatrised, the fingers being kept apart with lint. Mr. Mason showed a cast of the deformity before he had operated.

Mr. MAUNDER showed a girl of 15 years of age with an exostosis of the femur, which he had broken off with a large

pair of forceps (borrowed from the gasfitter) without any incision. The piece had become reunited in spite of daily motion, but the great pain was relieved and free action of the leg and thigh acquired.

# Dr. J. MILNER FOTHERGILL then read a paper on THE MUTUAL RELATIONS OF THE DISEASES OF THE HEART AND RESPIRATORY ORGANS.

He said, whenever there exists disease at the mitral valve the blood-pressure in the pulmonic circulation is increased. The capacity of the thorax is often diminished by attacks of congestion and dyspnoic results. The pulmonary vessels are thickened and dilated, and a similar condition exists in the muscular chamber of the right heart. There is often a development of connective tissue in the lungs, which may possibly give strength to the lung-tissue, and protect it from rupture in the violent respiration so often found in mitral disease. There may be rupture of the blood-vessels and hæmoptysis, or the formation of the infarctus Laennecii. The nerves of the lung are not structurally altered, but congestion of the lungs produces the dry, harsh cough, pathognomonic of cardiac disease. The effects of venous congestion are felt in the bronchial veins, and in advanced cases there is usually bronchorrhœa. Some were inclined to regard this as due to the increased pulmonary congestion; but the clinical fact is, that this so-called bronchitis is best relieved by digitalis, which increased the blood-pressure in the pulmonic circulation. The true pathology is fulness of the bronchial veins. The pleuritic effusions of advanced heart-disease are also due to general venous fulness. At other times diseases of the respiratory organs induced change in the right side of the heart. A case recently recorded by Dr. A. W. Foot showed that as well as right side hypertrophy there was enlargement of the pulmonary artery and its valves, by a hyperplasia of cell-elements not passing into inflammation. Commonly, disease in the lung led to disease in the circulation; but, as Niemeyer pointed out, this was not the case in the diminished bulk of blood in pulmonary tuberculosis. Frequently, in acute disease of the respiratory organs, death threatened from exhaustion in the right heart, where there was pre-existing mitral disease. Attacks of bronchitis were very fatal, unless the right heart were remembered in the treatment. In the treatment of diseases of the heart and of the respiratory organs, the true pathological sequences must be borne in mind, and certain consequential changes foreseen and guarded against.

# MEDICAL MICROSCOPICAL SOCIETY.

Mr. JAEZ HOGG President, in the Chair.

At the first meeting of this Society, for the session 1874-5, a paper communicated by Mr. John Gorham, of Tunbridge, "On a New and Expeditious Method of Micrometry," was read by the President.

The principle of the instrument described depended upon the measurement of lines drawn parallel to the base of an isosceles triangle—the base of the latter being given—by means of the sides, which are divided into a known number of parts. The triangle is obtained by dividing through the centre a disk of brass, about 1½ inch in diameter and half an inch thick, and bevelled at the edge, so as to allow of its being embraced by a stout india-rubber ring, by which means the two portions are held in perfect apposition at the edges of the section. The line of section, for the distance of one inch from the circumference, is marked out into fractions of an inch—at least into thirty-two parts—a less number being insufficient to obtain accurate results. A piece of paper of known thickness is now inserted between the halves of the disk, and moved along till its edge touches the commencement of the marked inch, the elastic band retaining it in its place, and thus an isosceles triangle, or gap, is left, with a base the thickness of the slip of paper, and with an edge of one inch, divided, as stated, into thirty-two equal parts. If a hair or cobweb be passed along the slit from base to apex, it will be arrested somewhere, and by reading off the number opposite which it stops, a simple matter of multiplication, the base of the triangle being known, will give the diameter required. For microscopic purposes the instrument is placed on the stage, and the object to be measured, placed on a thin glass cover, is slid over the aperture till it exactly at one point spans it. The diameter is then read off. To obtain still greater accuracy, Mr. Browning has added a

screw of known value, to separate the halves of the micrometer in lieu of the slip of paper.

It is apparent, from the ability to calculate by the aid of an isosceles triangle the value of all lines parallel to its base, such a figure would doubtless have been used long ago for measuring minute bodies if only bases sufficiently small and of known value had been placed within our reach; these being discovered, there would seem to be no real obstacle to the measurement of particles occupying such small portions of space as to be limited only by the confines of (so to speak) nothing. It is certain that no substance however small can elude the vigilance of such an instrument, and no substance, if the instrument be properly constructed, can even slide to its apex.

In answer to some questions by members of the Society, the President replied that the instrument was specially designed for unmounted objects, the thickness of an ordinary glass slide being rather an objection in the case of mounted ones. A thin glass cover might be in all cases employed for placing the specimen, *c.g.*, blood, or pus, upon.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 18, 1874.

### MR. STANSFELD AND THE CONTAGIOUS DISEASES ACT.

It needed none of Mr. Bouverie's prophetic spirit to enable anyone to divine the cause of the downfall of the late Ministry. The elements of destruction were too plainly visible to those who were watching the doings of many of the men Mr. Gladstone was unwise enough to admit into his counsel. The Ayrtons and Stansfelds did what they could to repel and offend his best friends and disgust the public mind. Such men were quite in their element when they were treading on every one's toes that came in their way. But it is most unpardonable that they should now be putting on an aggressive demeanour towards their chief, and endeavouring to bring discredit on the doings of the party with whom they were supposed to be acting in concert. Mr. Stansfeld one fine morning, finding himself at the head of a department he was utterly incompetent to conduct, hit upon a mode of concealing his ignorance by seeking to disgust and drive out of the office those better able and fitted for the work than himself. The able work of years, as well as the men who had inaugurated and carried it on successfully was thus very nearly sacrificed to the country. The "blundering and plundering" stupidity of this member of the Cabinet was fortunately brought to an early close by the falling to pieces of his party.

Two or three weeks ago Mr. Stansfeld reappeared on

the political stage as an opponent of the Contagious Diseases Acts, which he denounced, as putting a restraint upon the liberty of the subject. He seemed bursting with indignation, for he exclaimed, "I have marked these things—I have put my hand to the plough; I have cast in my lot with those men and women for ever revered in their names, as they led a forlorn hope: and never will I desist, and never will they desist from this sacred agitation until these degrading laws are blotted out from the statute-book for ever." We cannot help wondering how this right honourable gentleman stood quietly and tamely by when in office—nay, assisted his colleagues to enact a law which he now feels it a sacred duty to resist.

There can be no doubt that Mr. Stansfeld was in earnest, for last week he addressed another meeting, which was held at Bradford, under the presidency of Sir H. Johnstone, M.P., to promote the repeal of the Acts. There were, he said, two things which would have to be done towards securing their object—first, to induce religious denominations and other organisations concerned in the moral and religious welfare of the nation to take up the question; and, secondly, to show that the question had never yet been dealt with in a truly scientific spirit. A medical association in support of the movement had just been started, and it was already a great success. He was not in favour of the League attempting to make this a test question at Parliamentary elections. They should extend their organisation to all parts of the country. Sir H. Johnstone said he had undertaken to bring in a bill for the repeal of the Acts during the next session of Parliament.

We hardly congratulate the opponents of the Acts on the accession of Mr. Stansfeld, and may add that this is not the only way of showing his contempt for the profession. The position of the MEDICAL PRESS on this question is known, and is, we believe, more independent and more just than that of the other medical weeklies which have taken up a violent prejudice. We have, however, no taste for C. D. A. literature, and we view with indignation the proposal to set religious denominations by the ears on a subject which would thus be forced on the notice of people who should remain ignorant of it.

### THE ACTION OF DRUGS.

#### III.

THE third section of Professor Bennett's report contains various experiments, undertaken in order to determine whether there be any antagonism between hydrate of chloral and Calabar bean.

In seven cases extract of Calabar bean was given a few minutes after the hydrate of chloral, and the result seems to show that if the Calabar bean be given when the animals are completely under the influence of chloral the symptoms are modified, and the fatal result postponed. Then twelve experiments were made to ascertain more precisely, by the application of a crucial test, whether or not life could be saved from a fatal dose of extract of Calabar bean, and it was found that five out of seven rabbits survived; and these animals were killed eight days after by the same dose of extract of Calabar bean, without previous administration of chloral, in from six to fifteen minutes.

We here note, however, that although in the former

report *three-quarters* of a grain of extract of Calabar bean was given as the minimum fatal dose for a rabbit weighing 3 lbs., yet in Experiments 239, 243, and 244, rabbits, each weighing 3 lbs., recovered when *two-thirds* of a grain of extract of Calabar bean was given after fifteen grains of chloral, but died from same dose given alone some days after. And in Experiment 247 the rabbit weighed 3 lbs. 3 ozs., and succumbed to two-thirds of a grain of extract of Calabar bean. This, however, Professor Bennett accounts for by saying:—

“At this stage of the inquiry, it was found that the solution of the extract of Calabar bean supplied by Dr. Cook had evidently altered in strength, as two-thirds of a grain constituted a fatal dose for a rabbit weighing 3 lbs., instead of three-quarters of a grain as had been determined to be the fatal dose in the chloral-strychnia experiments. (See Table IX.) The difference between two-thirds and three-quarters of a grain is one-twelfth of a grain—that is, the fatal dose of the solution of extract of Calabar bean supplied by Dr. Cook had become one-twelfth of a grain less for a rabbit of 3 lbs. weight.”

In the next twelve experiments the extract of Calabar bean was given before the chloral, and, as Professor Bennett says, the experiments contained in Tables 17 and 18 “clearly show that, if hydrate of chloral be given before extract of Calabar bean, so that the animal is deeply under the influence of hydrate of chloral before it receives the extract of Calabar bean, the symptoms of the latter are much modified, and life saved from the effects of what would otherwise be a fatal dose. On the other hand, chloral hydrate is of comparatively little service as an antagonist to extract of Calabar bean if given some time after the latter. The reason of this is quite evident. Extract of Calabar bean produces its more severe physiological effects ten or twelve minutes after the administration of the fatal dose. In some cases the effects occur even sooner. On the other hand, a rabbit is not deeply under the influence of hydrate of chloral until fifteen or twenty minutes after it has been given. If the effects of extract of Calabar bean appear before those of hydrate of chloral, they usually run quickly to a fatal issue, because the antagonist, hydrate of chloral, is not acting with sufficient vigour to restrain them.

“It comes to be considered what is the nature of the physiological antagonism between extract of Calabar bean and hydrate of chloral. Is it a true antagonism, a neutralisation of the physiological effect of the one by that of the other? The effects of the one do not appear to be completely neutralised by those of the other. Even in those animals deeply under the influence of hydrate of chloral into which a fatal dose of extract of Calabar bean has been subsequently introduced, we do not find a complete absence of the symptoms referable to the presence of extract of Calabar bean. *There are still twitchings and startings, tremors, salivation, contracted pupil, &c.* (The italics are ours). But, on the other hand, the tendency to death by convulsions is obviated. If the animal be kept quiet, with a free circulation of air around it, it may recover. Cases of death after the introduction of both substances are to be referred to pulmonary congestion and the accumulation of fluid in the air-passages.

“From these experiments, it is evident that, in the

action of chloral hydrate and extract of Calabar bean, we have a good example of physiological antagonism (!!). This antagonism is, however, limited, as in all such cases, by two conditions: 1. *By the doses administered.* More than a minimum fatal dose of extract of Calabar bean destroys life, notwithstanding the administration of chloral hydrate. 2. *By the interval of time between the administration of the two substances.* There is a great probability of saving life in those instances in which both substances are given almost simultaneously. This probability is diminished if the chloral hydrate be given five or eight minutes after the extract of Calabar bean; while there is no chance at all if the chloral hydrate be given *more than eight minutes (!)* (italics ours) after a fatal dose of extract of Calabar bean. But even in those cases in which death occurs after the introduction of both substances, the effects of the Calabar bean are much less marked.

“These results must be regarded as very important. Several cases are now on record where ships coming from Africa have discharged Calabar beans on the shore, and which have been eaten by children with more or less poisonous effects. In such cases, the administration of chloral hydrate should at once be resorted to (within eight minutes we suppose). In Africa, fatal doses are designedly given by the ignorant natives as a test of guilt or innocence; and it will be well to remember that there it may not unfrequently occur that, as civilisation opens up the country to our missionaries and medical men, life may, in this way, not unfrequently be saved.”

Thus it is evident that, if the chloral hydrate be given more than eight minutes after a fatal dose of extract of Calabar bean, there is no chance at all of saving life. Such being the case, it is very doubtful if chloral would be of much practical value in the treatment of a case of poisoning in man by Calabar bean. And here again we incline to believe that the immediate inhalation of chloroform would be as efficacious, if not more so; it might be supplemented by the subcutaneous injection of chloral, so as to keep the patient some time under the influence. That the symptoms produced by Calabar bean are modified to a great extent when chloral is given first, and but slightly, if at all affected when the Calabar bean is given previously, we can quite understand when we remember Professor Fraser's experiments, showing that Calabar bean destroys the reflex functions of the cord, and eventually the conducting power of the nerves, which function chloral is evidently powerless to restore; in fact, chloral, through its primary action on the blood, depresses the reflex activity of the cord, and, if given first, only delays or prevents the *manifestation* of the action of the Calabar bean, simply because both drugs influence the same part. We must also bear in mind that, whereas, on the one hand, the Calabar bean exerts its influence almost immediately on introduction into the body (for in Experiment 119 a rabbit, after one and a-half grains, died in seven minutes), whilst, on the other hand, chloral (accepting Liebreich's theory) cannot commence to act till it has met sufficient alkali to decompose it, and thus set the chloroform free; moreover, the interval between the giving of the chloral and the development of its effects is most uncertain, and as yet it is difficult to say by what circumstances influenced, M. Byasson saying that the difference in the physiological phenomena is explained by

the intervention of formic acid, produced at the same time as the chloroform, and acting under special conditions, while M. Personne believes the combination of chloral with albumen explains the longer duration of the action of this body compared with chloroform.

The fourth section of the report under consideration still deals with Calabar bean, and may therefore be considered in connection with what has preceded. Morphia is next tried as an antagonist to Calabar bean.

Professor Bennett details the results of various experiments undertaken to ascertain the antagonism between hydrochlorate and meconate of morphia and Calabar bean. In the first place, nineteen rabbits were experimented on with hydrochlorate of morphia, to ascertain the minimum fatal dose, which Professor Bennett gives as *twelve grains* for a rabbit weighing 3 lbs., and states that "the predominant symptoms preceding death by a fatal dose were as follows: restlessness, contraction of the pupil, muscular twitchings, forward movements, convulsions, at first clonic, afterwards tonic—frequently at first there was a tendency to bending of the body forwards (emprostotonos), but always before death there was opisthotonos, that is, bending backwards." In the next place, ten rabbits were experimented with to ascertain the minimum fatal dose of meconate of morphia, and the conclusion arrived at was that about ten grains was the minimum fatal dose, the difference between the hydrochlorate and meconate being probably due to the superior solubility of the latter. Ten rabbits were then taken to test the question of the antagonism of morphia and Calabar bean. In five cases hydrochlorate, and in five meconate of morphia was given first, followed by extract of Calabar bean, and it was found that in all cases fatal results ensued. And Professor Bennett then concludes that these morphia salts are not antagonistic to Calabar bean.

In glancing over the various experiments recorded in the report, we note that *twelve grains* of hydrochlorate of morphia is given as the minimum fatal dose for a rabbit weighing 3 lbs., and that in Experiment 268 *five grains* given to a rabbit weighing 5 lbs. *only* produced drowsiness and contraction of pupil. Yet we find that *twelve grains* given to a colt produces muscular twitching, rigidity, restlessness, delirium, and increased action of heart, while *thirty-six grains* has been given to a horse without fatal results. But, according to previous researches, it only requires half a grain to narcotise a dog; (a) and probably less than a grain given in one dose would kill a man; (b) and in several instances one grain has proved fatal, and certainly a dose of two grains might kill a healthy adult unaccustomed to opiates. (c) Thus, we see that, *although* in all animals the influence of the drug is on the *same* parts, yet the effects produced vary greatly, according to the dose in different animals; this is a point that should be kept in mind when drawing inferences from experiments on animals.

It may not be out of place to observe that almost all lecturers on materia medica are in the habit of warning their students that many drugs poisonous to man may be

consumed with comparative impunity by many of the lower animals, and especially by the rodentia.

The conclusion arrived at by Professor Bennett in reference to the antagonism of morphia salts and Calabar bean is what we should naturally expect, for as both drugs act upon the same part—viz, the spinal cord—although the morphia also acts upon the cerebrum—partly as an excitant, partly as a depressant—and also deranges the function of the vagus nerve, thus depressing and enfeebling the heart's action—while, as we have already stated, Calabar bean destroys the reflex function of the cord, so we could hardly expect these drugs to antagonise each other. Thus, we see in Experiment 275 a rabbit weighing 4 lbs. recovers after thirteen grains of hydrochlorate of morphia, while in Experiment 293, to one of same weight was given three grains of hydrochlorate of morphia, and in six minutes two-thirds of a grain of extract of Calabar bean, and death ensued in seventeen minutes. Thus, although less than the fatal dose of each drug was given, the result was death, clearly proving that these drugs are the opposite of antagonists to each other.

## Notes on Current Topics.

### Toxic Quality of the Flowers of the *Colchicum Autumnale*.

WE noted very recently the occurrence of cattle poisoning in the county of Mayo, which was stated by the local paper to have been traced to the eating of the *Colchicum autumnale* by the stock on the land. The existence of a serious poison in the flowers of the plant had not hitherto been generally known. But we observe that a letter on this subject has been recently communicated to the French Academy, and is published in the *Comptes Rendus*. M. Pierre, the author, says that, having plucked some fully-expanded flowers in order to examine them more closely, he was surprised to notice that, after a few seconds, his fingers had changed colour, and taken the livid greenish yellow tint characteristic of a corpse in a state of incipient decomposition. After about ten seconds the skin regained its usual colour. As the discolouration extended throughout the length of the fingers, and even beyond, the question arose whether or not it was caused by absorption by contact at the extremity of the fingers. M. Pierre therefore extended his hand over a large clump of flowers, and carefully avoided all contact. The same phenomenon was produced with the same rapidity, and disappeared as quickly when the hand was removed. The experiment was repeated several times, and by different persons, but always with the same result.

Upon comparing the flowers capable of producing the phenomenon with those which appeared to have lost the power, it was noticed that the inactive flowers had commenced to fade, and that the pistils and filaments of the stamens were much paler in colour than on the preceding day, or than those of less advanced flowers. He therefore thinks it presumable that it is principally during or approaching the act of fecundation that the colchicum flower possesses in the highest degree the property above described.

(a) Dr. John Harley, "The Old Vegetable Neurotics." Burness and Mavor, "The Specific Action of Drugs," p. 131.

(b) Dr. Guy, "Forensic Medicine."

(c) Dr. Tanner "On Poisons."

The substance in the flower capable of producing this effect, the author thinks, is probably an extremely volatile substance which has not yet been studied. In this view he is supported by the fact that after a number of experiments, without contact, and without raising his hand to his mouth, M. Pierre experienced in the organs of taste a peculiar sensation (*sensation vireuse*), whilst his assistant, using the same finger many times, experienced a numbness in it which was persistent during several hours.

In connection with this action of certain principles of the colchicum flower, the author remarks that in the Gâtinais, where saffron is cultivated on a large scale, some persons, especially among women and children, cannot work at plucking the flowers without suffering from the symptoms of a peculiar poisoning, which manifests itself externally in a swollen and bloated appearance.

### Cutaneous Medicine.

DR. H. S. PURDON, Physician to the Belfast General Hospital, and to the Hospital for Diseases of the Skin has in the press a volume on this specialty. Dr. Purdon's work will contain the results of ten years' observation at the Belfast Hospital for Diseases of the Skin, embracing several new features as regards the successful treatment of certain forms of cutaneous affections.

### The late Dr. Anderson.

WE regret, says *Nature*, to have to record the death at Chiswick, on the 2nd inst., of Dr. Thomas Anderson, late Professor of Chemistry in the University of Glasgow. Dr. Anderson was born in 1819, and was educated at the University of Edinburgh. On leaving college he visited Stockholm, where he studied for some time under Berzelius, and afterwards went to Gießen and studied under Liebig. Returning to Edinburgh, he acquired considerable reputation by teaching chemistry in the Extra Academic Medical School at Edinburgh, and whilst so engaged received the appointment of consulting chemist to the Highland and Agricultural Society. In 1852 he succeeded Dr. Thomas Thompson as Professor of chemistry in the University of Glasgow, and discharged the duties of the Chair with great acceptance until 1869, when he was incapacitated from work by a paralytic seizure. Having had another attack of paralysis in May of the present year, he resigned his professorship in July last. Dr. Anderson was the author of several papers on the organic bases, especially those bases obtained from opium and coal-tar, and in the destructive distillation of animal substances. In a paper on "The Chemistry of Opium," read before the Chemical Society in 1862, he described a valuable method of extracting the alkaloids of opium, and determining their relative qualities.

### Paris Academy of Medicine.

PROPOSALS for the "reform" of the Paris Academy of Medicine are being carefully discussed by that body. It is proposed to reduce the number of members from 100 to 60.

### Paris Medical School.

THE Paris medical students have again been indulging their political prejudices by insulting a newly appointed

professor, supposed to be *clerical* in politics. They would have shown more sense by listening to what he had to say on pathology. The school has been closed for a time, and we hope when it reopens these silly young fellows will have found out that political views do not influence scientific teaching, and that rowdiness in the lecture theatre is a disgrace to any body of students.

### Is a Workhouse Infirmary an Hospital?

THE *Observer* understands that at the weekly meeting of the Chelsea guardians this question was raised under very peculiar circumstances. A woman had cut her throat, and Mr. Turner, one of the medical officers, on being called in, finding her sinking from loss of blood, took her to the workhouse infirmary, as being the nearest place to obtain proper assistance; but she died, and he was compelled to hear that the guardians considered his conduct "reprehensible." Mr. Turner sent a letter explaining the case, and expressing surprise that the action of a medical man in endeavouring to save the life of a fellow-creature, should be thus designated. It came out that the term "reprehensible" was only the expression of one individual guardian of the name of Birch. The board declared Mr. Turner's conduct satisfactory, but as a general principle it was not advisable to convert the workhouse infirmary into a hospital by admitting accidents into its wards.

### The Value of Oatmeal as Infants' Food.

IN a communication to the Société Médicale des Hôpitaux, MM. Dujardin-Beaumetz and Hardy make known the results of the employment of oatmeal on the alimentation and hygiene of infants. According to them, oatmeal is the aliment which, by reason of its plastic and respiratory elements, makes the nearest approach to human milk. It also is one of those which contains most iron and salts, and especially the phosphate of lime, so necessary for infants. It also has the property of preventing and arresting the diarrhoeas which are so frequent and so dangerous at this age. According to the trials made by Mr. Marie, infants from four to eleven months of age fed exclusively upon Scotch oatmeal and cow's milk thrive very nearly as well as do children of the same age suckled by a good nurse.

### Vitality of Jews compared with that of Christians.

A WRITER in the *Philadelphia Reporter* communicates several facts which are worthy of consideration. He addressed letters of inquiry to all the prominent Jews in the United States, asking the question, "Do the Jews ever have consumption?" From every quarter he received one reply—"The disease is very rare among them." The writer states that in an extensive practice he never saw a single case of consumption among the Jews.

Why this comparative immunity from this disease? Answer to this is made by quoting (1) tables of vital statistics made up from observations in the great centres of civilisation—England, Germany, France, &c. These tables revealed the following remarkable facts:—

In the first five years of life, of 100 Jewish children, 12 die; of 100 Christian children, 24 die. Among 100 Christians, 38 attained to 50 years. Among 100 Jews,

54 attained 50 years. Thirteen Christians in 100 attain 70 years, while out of 100 Jews, 27 attained 70 years. One quarter of all Christians attain only 6 years and 11 months. One quarter of all Jews attain 28 years and 3 months.

(2) In explanation of these facts, Dr. Neufville gives the following facts: There are no proletarians among the Jews, while one-tenth of the Christians live on charity. The difference between the Christian and Jewish merchants is strikingly pointed out by the tables before quoted. These show that among 100 merchants, one-half of the Christians die before 57, while one-half of the Jews live until 67. Why this greater relative longevity, this greater immunity from disease, and tenacity of life among the Jews than among the Christians? Is it from their rigid adherence to articles of faith and the hygienic, sanitary, and dietetic regulations of their religion? The *Pacific Medical Journal* remarks that a careful scientific inquiry into the cause of the above facts would be of incalculable benefit. If it should be found that obedience to physical and other laws was the cause of their physical strength, &c., then we should learn how to rejuvenate consumptive and other degenerate classes.

#### Hay Fever Sufferers.

THE hay fever refugees among the White Mountains have formed a permanent association for the discovery and spread of whatever promises to relieve or cure the malady.

#### Homœopathic Surgery.

RECENT criticisms of the Philadelphia newspapers as to the efficiency of the Homœopathic Hospital in that city are the reverse of flattering. It appears that by an extraordinary order of the Mayor, accident cases have of late been carried by the police to that institution, and a death having occurred, a coroner's inquest was held, which returned a verdict that death was due to delay in medical treatment, and that the physicians in charge were in the highest degree censurable.

#### Irish Visitors of Examinations.

WE note in the columns of the *British Medical Journal* a letter from a "Fellow of the King and Queen's College of Physicians in Ireland," in which the statement that the names of certain gentlemen had been "sent up or recommended" by the licensing bodies to the Branch Council is categorically denied. Inasmuch as the statement in question was copied directly from the MEDICAL PRESS AND CIRCULAR, we feel it necessary to repeat that—at least, as regards the great majority of the licensing bodies—it is perfectly accurate. The Council of the Royal College of Surgeons did send forward the names only of those Fellows whom they recommended, although there were many other candidates, and we believe that the University of Dublin and the Apothecaries' Hall followed the same course. As regards the Queen's University, the statement contained in our journal, and repeated in the *British Medical Journal*, turns out to be not equally accurate. No names of graduates were recommended from the Senate, but the reason was not—as our statement implied—a refusal on the part of the Senate to co-operate. The fact is, that in the hurry of the examinations,

which were at that time going on, the matter was overlooked.

### Horse-hair Sutures.

DR. FAYRER says, in a recent work: "Well selected white hair out of a horse's tail is, in many respects, better than any suture hitherto devised. . . . That from the tail of a white or grey horse is the best. I hardly know why it should be so, but I find the white is better than the black hair."

### The Visiting List.

ALREADY Messrs. Smith and Co. have issued their invaluable—nay, almost indispensable, companion for 1875. So well is the work known, and so often have we commended it, that we have nothing new to say of it. We have carried it in our pocket again all through the year, which the new edition reminds us is fast vanishing, and we hope to carry the List for 1875 through the coming year.

### The Dwellings of the Poor.

THIS may be considered as a question of special interest to the profession, and our readers will not have forgotten the action taken about it by the London College of Physicians. No doubt the question presses, and time passes while action seems delayed. It is therefore gratifying to record from time to time the attempts of philanthropists to bring home to Government and people the importance of this matter. This week Sir S. H. Waterlow has, at the suggestion of the right hon. gentleman, addressed to the Home Secretary a letter on the subject. Premising that the company of which he is chairman has already spent, and is about to spend, sums amounting to a total of £335,000 in providing dwellings for upwards of 9,000 persons, and that other associations and individuals have provided accommodation for about 20,000 persons, the hon. baronet says the only difficulty in the way of the rapid progress of the work is the impossibility of obtaining suitable sites in densely populated districts. It is of the greatest importance to the vast majority of the working classes that they should reside near the place of their employment, and to the markets for their trades. The efforts which have been made to lessen the evils of over-crowding and to improve the dwellings of the labouring classes, although they have had very beneficial results, do not reach the real evil, which is the inability, owing to the variety of interests in this kind of property, to purchase and

remove houses unfit for human habitation. Compulsory powers are necessary, and these ought only to be exercised by some public authority. Sir Sidney Waterlow suggests that the Legislature, recognising the local authority which the Metropolitan Board of Works and the City of London exercise over the districts under their control, should impose upon these two public bodies, or upon some other public authority, or upon public commissioners, the responsibility and the duty of submitting to Parliament, from time to time, schemes for public improvement, involving the destruction of houses unfit for occupation, and the appropriation of the sites when cleared for the reconstruction of tenement houses suitable for the labouring population, upon plans to be approved by the local authority. The various interests concerned would, of course, be compensated in the same way as if the property were taken for a street improvement. A sum of £2,000,000, the interest and repayment of which would be provided for by a rate of 1d. in the pound in the metropolis, would, if applied in the mode suggested, remove to a very large extent the houses in the metropolis at the present time unfit for human habitation. Sir S. Waterlow further suggests that the Public Works Loan Commissioners should be empowered to make loans to companies and individuals, as well as to local authorities, for the construction of dwellings for the working classes in populous places, at a lower rate of interest than four per cent. on the security of the property.

### Losses in War.

M. CHENU, Medical Inspector-General of the French Army, reports the losses sustained by the French to be as follows:—Killed, disappeared, or died of wounds and diseases, 138,871; wounded by the enemy's fire, 143,000; men disabled by marching, 11,421; 11,914 missing are treated as dead. These figures include 2,881 officers killed or who died of wounds and disease, and 96 missing, with 17,240 prisoners who died in Germany, 1,701 in Switzerland, and 124 in Belgium. While 17,240 deaths, then, occurred in captivity, only 1,220 soldiers were killed at Gravelotte, the bloodiest battle of the war. The German losses were:—Killed or died of wounds and disease, 40,741; missing and treated as dead, 4,000; wounded, 127,867. To these have to be added 1,795 killed, 6,600 wounded, and 1,539 missing in skirmishes, patrols, and slight engagements. The Germans had 44,000 deaths, the French, 138,871; the Germans 127,000 wounded, the French 143,000. The French had 11,421 men disabled by *plaies de marche*—that is, through defective socks, boots, and gaiters, while the Germans suffered but little from this cause. M. Chenu shows that in the Crimea and Italy, as well as in the last war, disease was more fatal than the sword, this being partly attributable to commissariat, outfit, and hospital shortcomings.

IN London 2,579 births and 1,446 deaths were registered last week. The births exceeded by 139, whilst the deaths were 140 below the average of the corresponding week of the last ten years. The annual death-rate, which in the last week was at 20 and 21, rose last week to 22 per 1,000 of the population.

### Proposed Reconversion of Hospital Buildings.

LAST week the Hampstead vestry had an excited meeting upon the question of the reconversion by the Metropolitan Asylums Board of the Hampstead Hospital buildings as an establishment for contagious diseases. A report from a few members of the profession was presented, stating that the site was most inappropriate. Not only were there several schools in the neighbourhood, but being in a hollow by the side of a hill, the contagion would be carried in a direct line down the Fleet Valley to the heart of London. It was also pointed out that there was a large establishment, the Orphan Working School, in close proximity. Upon the motion of Mr. Le Breton, member of the Metropolitan Board, a resolution was adopted declaring the site as wholly unfit for the purpose, and that a deputation wait upon the Metropolitan Asylums Board for the purpose of enforcing their views, and to try every possible means for the removal of the hospital.

### Scarlet Fever in the Metropolis.

THE Registrar-General reports that the deaths from scarlet fever, which in the two previous weeks had been 105 and 123, declined last week to 107, viz., 39 in the east, 25 in the north, and 22 in the south group of metropolitan districts. The annual death-rate from the disease averaged 1.6 per 1000 of the population. The disease was especially fatal last week in Shoreditch, Bow, and Poplar.

### Edinburgh University.

THE election of Lord Rector of this University took place on Saturday last, and resulted in the election of Lord Derby by a majority of 187 votes over Dr. Lyon Playfair. There was the usual amount of noisy rivalry between opposing factions, and the students indulged in those gentlemanly pastimes of pea-shooting, flour and rotten-egg throwing to their hearts' content, and to the no small annoyance of those who were specially singled out for their attention.

### The Wine Question.

A DINNER was given by the Portuguese Government in London on Saturday last, which possessed both political and commercial significance. The Portuguese were the largest exhibitors at the International Exhibition, now closed, having placed at the disposal of the public for tasting purposes the enormous quantity of 24,000 bottles of various kinds; and as a graceful compliment to the English press, and a fitting close to the recent Exhibition, this dinner was given. Dr. Frankland, Mr. Brudenell Carter, Mr. Gaskoin, and other members of the profession were present, presided over by Dr. De Aguiar, the Commissioner to the Portuguese Government, and a chemist of European celebrity. During the evening twenty-seven unfortified and unadulterated wines, the production of the various districts in Portugal, were passed round and enjoyed by the company present. In the course of his speech, Dr. Frankland remarked that, when wine came into contact with chemistry it was frequently a very suspicious matter, but having free access to the cellars at the Inter-

national, he had taken great interest in these wines, and the results of his analyses were eminently satisfactory, in fact, they confirmed the old adage, that "good wine needs no bush." The President, Dr. De Aguiar, delivered a most exhaustive speech in French, paying a graceful compliment to the wines of Hungary, which country was also represented by a commissioner present, and condemning very strongly the vitiated taste for brandied wines, and the abominable systems of almost universal adulteration which pandered to such tastes. Altogether the meeting was both enjoyable and instructive, and the thanks of all present were unanimously voted to Dr. De Aguiar for his courtesy.

### Progress of Cremation in Germany.

A SECOND act of cremation was successfully performed on the 6th inst. in the same oven at Dresden in which the body of Lady Dilke was recently consumed. The body was again that of a young married lady, twenty-three years of age, the wife of a South German physician. The hall around the furnace was decorated with flowers, and in every other respect the solemnity which should attend so serious a rite was duly observed. No clergyman could, however, be found to take part in the ceremony and speak a burial address over the dead body; so Herr Siemens, the constructor and proprietor of the oven, delivered a brief but impressive speech, after which the coffin was committed to the flames. The process of cremation was screened from the eyes of the lady's friends by an iron door, but a small number of physicians and other scientific men witnessed the operation through a slit in the wall. They describe the spectacle as free from anything offensive either to the senses or the imagination. The current of hot air burning up the body appeared as a transparent flame of a pale reddish hue. There was no smoke or any unsightly transformation of the body. When the coffin was consumed the body appeared in its natural state, then red hot, and at last appeared to be of translucent white. From this it crumbled into ashes. Up to the period of its entire consumption by the flames the process was merely as a rapid drying up. After seventy-eight minutes all organic matter was gone, and nothing remained but a small heap of ashes, which was conveyed away in an urn.

### Counter-Practice and "Simples that can do no harm."

DR. BUCKINGHAM, the Professor of Midwifery at Harvard University, publishes in the *Boston Medical Journal* some very admirable observations on the mutual relations of druggists and physicians, in the course of which the following cogent remarks occur:—

"There is one matter of interest to all of us, and to the public as well, which I am not sorry to have an opportunity to allude to. I refer to the habit which some druggists have of prescribing. 'Well,' say you, 'why is not my prescription as good as that of any old nurse, or any other neighbour who has strayed in?' It is exactly as good, and no better. The sore-throat, of which you know nothing, may be the result of insufficient dress, or of almond candy. The diarrhoea may be the beginning of a typhoid fever, or from want of flannel drawers. The constipation may be owing to too little food, or approaching disease of the brain. All of them may be simply

symptoms of dyspepsia. One dyspepsia may require an acid, another an alkali; one needs a dose of physic, another requires food; one wants out-of-door air, and another a warm bed. One needs to have the patient stop his head-work, and another would be benefited by any change from his present style of life. Cough may have cause in the head, in the throat, in the lungs, in the stomach. The very medicine which you give, without knowledge of the particular patient, and how to examine him, may be the means of aggravating the disease.

"To say that this medicine is very simple, and if it does no good, cannot do harm, is one of the most common of mistakes. If no other harm is done by it, there may be serious loss of time. But what is a simple remedy? You, perhaps, will say 'tollu, ipecac, castor-oil, salts, rhubarb.' If a man asks you for a compound cathartic pill, or for a dose of paregoric, that is all very well. I know of no reason for refusing him. If he asks you what the best cathartic for him is, or what would do his cough the most good, that is a very different matter. You know, and can know, nothing about it. If one man's meat is another's poison—and this is literally true—the parallel comparison will hold equally good concerning medicines.

"I have a case on my books which is a fair, but ludicrous illustration of the value of such prescriptions as are 'simple, and can't do any harm.' I was called to see a little girl, who had been kept at school on Saturday till after her usual dinner hour. When she got home, vexed and tired, notwithstanding she had a slight headache, a slice of beef-steak would have relieved her. The headache led the mother to give a dose of castor-oil, and to offer gruel, which was refused. Sunday, no improvement, and tincture of rhubarb was taken. On Monday, no better; senna and salts. Tuesday, no better, and a dose of elixir pro. On Wednesday afternoon I was called in, and informed by Mrs. — that, having no other medicine in the house, she had given the little girl an emetic, and it had brought up a great deal of bile, and she feared the child would never recover. The advice given was to feed the and let medicine alone. Yet these were all what are called simple medicines. With the exception of great weakness and loss of flesh, the child was in her usual health in twenty-four hours.

### A Deadly Medicine.

UNDER the above title the *Globe* of Friday last published the following remarks:—

The evidence given before a recent inquest at Manchester deserves attention, as proving the great danger attending the use of certain drugs that have come into fashion during late years. A man named Alfred Holme, being troubled with some sort of nervous headache, was recommended by a friend to try hydrate of chloral as a remedy. Following this foolish advice, he sent for a 6 oz. bottle of the compound on Monday, and within twenty-four hours he was found dead. According to the medical evidence the man's death was *syncope cordis*, produced by the action of the hydrate on a weak heart. The doctor who gave this testimony also stated that hydrate of chloral is very little understood even by medical men, he himself being ignorant as to whether its effects are cumulative. This allegation of general want of knowledge regarding the power of the medicine was corroborated by the chemist who sold the dose to the dead man. Yet, although it was his opinion that the hydrate of chloral ought not to be given except under medical advice, he appears to have made little inquiry when making up the prescription brought to him by Holme's daughter, a little girl about eight years of age. As the bottle contained 6 oz., while the label directed a tablespoonful to be taken every two hours, the unfortunate man was virtually instructed that he might with safety drink within every four-and-twenty hours what was almost certain to kill any one with a weak heart. The sad results following the use of the medicine in this case will, it is to be hoped, render hydrate of chloral and similar strong physic less fashionable. Unless perfectly

acquainted with their constitutions, people who fly to these remedies for relief may inadvertently be running the risk of death.

We quote this paragraph, although it contains but an incomplete history of the case, inasmuch as it would be well if all the organs of public opinion would set themselves against the too prevalent folly of indulging in the luxury of taking powerful drugs without medical advice. Injury is constantly done by such conduct. Too often life is thus sacrificed.

OUR Berlin contemporaries report that seventy-six cases of trichinosis have occurred among the garrison of that city.

Two men were last week suffocated in a nursery garden at Edinburgh by the vitiated air from a hothouse entering a lobby where they were sleeping.

A CASE of hydrophobia was reported last week at Manchester, the patient having been bitten by a stray dog, and death having resulted from the bite. A verdict in accordance with this evidence was given.

PROFESSOR ROLLESTON has been appointed to represent the University of Oxford, and Professor Humphry to represent the University of Cambridge in the General Council of Medical Education and Registration for the next five years.

THE Local Government Board have written to the Thurles Board of Guardians with respect to the salaries allowed by them to the sanitary medical officers. They consider the sums named totally inadequate.

LAST week the highest rate of mortality from typhoid fever was reached since the commencement of the outbreak—twenty-four persons having died. Although there have been so many fatal cases, Dr. Handle, the medical officer of health, states that the fever is now subsiding, that the fresh cases are comparatively few, and that the old ones are rapidly passing into convalescence.

CERTAIN alterations to secure isolation of the inmates of the Norwood schools, which have recently been visited with a severe outbreak of scarlet fever, were suggested at the last meeting of the board, and an instance was adduced in which fever had been introduced into one of the establishments of the board by means of a woman and a child who had come from an infected room visiting it. Thereupon the board of guardians very properly and promptly resolved that visitations to the several establishments under their control should be suspended during the prevalence of the epidemic.

THE India Museum will be arranged, by an efficient staff. Dr. J. Forbes Watson retains his appointment of Chief Reporter on the Products of India, and becomes Director of the Museum. The appointment of Assistant Reporter on the Products of India and Curator of the Museum has been conferred on Dr. Birdwood. Mr. Moore, Dr. Cooke, and Lieut. Royle—each of whom has made his

mark in the scientific world—have received appointments as assistant curators.

THE *Philadelphia Reporter* publishes one of the most remarkable series of coincidences on record, taken from the statistics of Iowa and Georgia in the matters of insanity, blindness, &c. The populations are given as follows:—Georgia, 1,185,000; Iowa, 1,182,933 (the national census made them 1,191,792 and 1,184,103 respectively), and the following were the showings of the two States as to their unfortunate classes:—

	Georgia.	Iowa.
Insane . . .	1,185	1,183
Idiotic . . .	790	789
Deaf and Dumb . .	677	676
Blind . . .	474	473

## Literature.

### NORTON'S OSTEOLOGY. (a)

WE welcome the new edition of Mr. Norton's "Osteology," which will be found of material assistance to the tyro in anatomy. It has frequently been said, and with truth, that a thorough knowledge of the bones is not only the best introduction to anatomy, but renders every other branch of that science comparatively easy. Mr. Norton's work possesses the cardinal merits of clearness and brevity. The descriptions, though less detailed than those of Ward, will, we believe, be found quite sufficient, and, by the aid of the plates, cannot be misunderstood. These plates, twenty in number, are beautifully executed, and may either be had separately, or bound up with the text in a single volume. The letterpress, too, deserves a word of commendation. Indeed, the work, as a whole, reflects credit on author, artists, and publishers alike.

The first portion of the work contains a concise description of each bone in the human body, with small numerals above the line referring to each point shown in the plates. These numerals are one of the improvements introduced into this edition, and cannot fail to arrest the student's attention. They save him the trouble of searching amongst the references attached to the plates for the point required.

The second portion of the work, or the "Atlas," which, as we have said, may also be had bound separately, is furnished with another set of references opposite to the figures. Thus, the Atlas may be used not only while reading the text, but also alone, for the purpose of self-examination, an exercise the student cannot too often indulge in. The author, however, cautions students against trusting to the plates alone, and urges them to have the bones constantly before them. This is undoubtedly good advice; but we believe that such plates as these cannot fail to assist him. The chapter on "Ossification" has been extended in this edition, the author, since the publication of the first, having himself made numerous dissections of fetal bones of different ages. The results are embodied in this chapter, which contains a fair summary of our present knowledge of the subject.

We have only met with one misprint, and that a trivial one—viz., the figure 8 being repeated twice, instead of 8 and 9, on page 16, line 4.

In a future edition, which the work deserves to reach speedily, Mr. Norton might add to its utility by including in the index the names of the muscles and ligaments mentioned in his descriptions.

By Arthur Trehern Norton, F.R.C.S., Assistant-Surgeon, Surgeon in charge of the Throat Department, and Lecturer on Anatomy, St. Mary's Hospital: Second Edition. London: Baillière, Tindall, and Cox. 1874.

### ARCHIVES OF DERMATOLOGY. (a)

THE first number of an American journal, devoted specially, though not exclusively, to the illustration of cutaneous diseases, has reached us, and it is got up in such a creditable manner and well edited, that we gladly welcome its appearance.

The first article in its pages is with reference to *Rothela*, or German measles, which is described with care and clearness by Dr. J. Lewis Smith. He observed the epidemic in New York from the close of 1873 to May, 1874. It will be read here with more interest, as a wide-spread epidemic of the same affection has for several months past occurred in this city, and dropping cases are still often met with. Dr. Smith speaks decisively on the point of *Rothela* being completely distinct from *roseola*, *measles*, and *scarlatina*, and states what other observers are fully agreed on, that it does attack children who a short time before or afterwards run through a well-marked attack of true measles. Thus, out of forty-eight cases seen by him up to May 1st, at least nineteen had had measles, and one who had the *rothela* took measles a month subsequently. Also "in the Foundling Hospital *rothela* closely followed an epidemic of measles. A considerable number of the children affected with the former disease had recently recovered from the latter." With regard to the distinction between it and *scarlatina*, Dr. Smith says: "That *rothela* is not a form of scarlet fever is evident from the fact that, as regards at least the New York epidemic, the rash was in most instances quite different from the scarlatinous effervescence, occurring, as we have seen, in small more or less circular points and patches. Moreover, there is in *rothela* a slight febrile movement, and general mildness of symptoms, quite unlike what we observe in *scarlatina*; or if there is a considerable febrile movement, it is of short duration. But the decisive proof of an essential difference between these two diseases is found in the fact already stated in regard to measles—namely, that an attack of the one malady does not prevent the occurrence of the other. There are, it is true, cases in which it is difficult to make the differential diagnosis between *rothela* and mild measles, or mild *scarlatina* at first; but when the course of the malady has been closely observed for three or four days, it rarely happens that we are unable to make out its character."

There is also a good descriptive paper upon *urticaria*, by Howard F. Damon, M.D., with reference to its frequency and varieties. Close upon 300 cases form the basis of his descriptions, which are drawn up with clearness and ability. We should hope that another paper, giving us some good general rules for the treatment of this Protean and troublesome symptom will reach us ere long. The attention Dr. Damon has devoted to tabulating its various external appearances convinces us that he has watched it with unusual care, and is most competent to offer us the desired paper on its rational treatment.

Dr. Bulkley contributes a short but suggestive paper on "Cases of *Herpes Zoster Frontalis* successfully treated by Electricity." The attack occurred to a lady, thirty-six years of age. The eruption had appeared five days previously. The right forehead was covered with groups of vesicles and bullæ, also the upper lip, eyelid, and through the scalp on the same side numerous clusters could be seen or felt. The right eye was closed by oedema of the lid, but the cornea was intact. She complained of intense and pretty constant pain through the eye, running backwards, with occasional sharp accessions, causing her to cry out, and sleep had been entirely interrupted.

"May 30.—Electricity was applied by Dr. G. M. Beard last evening. A continuous galvanic current from eight cells was employed, the negative pole being placed indifferently on the back of the head, neck, and epigastrium, and the positive passed with a moist electrode over the eruption and pressed upon the eye. The relief obtained

(a) "Archives of Dermatology," No. 1, vol. i. Edited by Duncan Bulkley, A.M., M.D. New York.

was prompt, occurring in about three hours, so that she slept comfortably, and had no very acute pain since the first application. The electricity was subsequently applied daily, gradually increasing its strength until sixteen cells were used. (June 8), with the view of hastening the exsiccation, diminishing the amount of scarring, and relieving the slight dull aching pain that remained."

If subsequent observation confirms the assertions here made, a valuable addition to the resources at our disposal for treating herpes zoster will be secured; at all events, the question is worth investigating.

There is a copious "digest of literature" on various topics bearing on cutaneous affections that must cost the compilers much research and trouble. In conclusion, we can with truth say we wish this journal long life and prosperity, and its editor and his staff every possible success.

### "ON MYCETOMA, OR THE FUNGUS DISEASE OF INDIA." (a)

ON prosecuting an inquiry into the etiology of an obscure form of disease it behoves us to be cautious, lest a preconceived opinion should bias the judgment and lead one to look upon a plausible theory as a settled fact. The faculty of nice discrimination is certainly required for the investigation of a disease supposed to be of parasitic origin. A remarkable form of affection, confined to the extremities, and peculiar to the Indian climate, believed to be due to a fungus growth, was first observed some twenty years ago by Dr. Gill. An amputated foot was "found to be a mass of disease of a fibro-cartilaginous nature, with entire destruction of the joints, cartilages, and ligaments; it had neither shape nor feature, and was covered with large fungoid excrescences discharging an offensive ichorous fluid." Since then a most indefatigable observer, Dr. Vandyke Carter, has given much time and attention to the study of the disease, and published several papers in the journals on the subject; the results of his labour now for the first time appear in a collected form, and Dr. Carter hopes thereby "to render his data and illustrations more accessible than before, and to extend a knowledge of the fungus disease of India."

This monograph certainly furnishes a very interesting clinical and medical history of the Madura-foot Disease. The author prefers to designate it "Mycetoma," and by which he means "a tumour resulting from the growth within the textures of the human body of a simple organized vegetable parasite." There are, he tells us, "two chief varieties, presenting two colours, 'melanoid' and 'ochroid' (pale and dark), and the particles themselves which appertain to each variety are termed *sclerotia* and *malacotia* (hard and soft). Dr. Carter proceeds to give the local and general characters, the anatomy, pathology, progress, and treatment of the disease, and its natural history. In an appendix he furnishes a brief summary of its bibliography, while numerous well-executed drawings of mycetoma in all its varied phases greatly assist the reader to comprehend the nature of the growth.

The pathological characters of the disease are peculiar, although a fuller and more accurate account of its incubation, or rather its earliest stage, is even now much required. The patient, it appears, is seldom seen "before a sinus is formed in the soft parts, and a discharge of the particles commenced;" this naturally leads to an unsatisfactory "perhaps" as to how the fungus germs first pass inward, develope, and grow. More frequently patients present themselves with a foot or a hand (generally the former) much swollen, of a dark colour, and studded with numerous sinuses; the form of the swelling

is more or less globular, and as to its extent, the whole of the member, on one side or part only, may be implicated. In the former case the projecting fingers appear to be imbedded, being themselves generally free, and the sole or palm is flat, or even convex. Seldom does the disease extend beyond the ankle or wrist, and its whole appearance, at first sight, somewhat resembles a long-standing scrofulous affection. The sinuses are many in number, and often clustered together about the sole, ankle, or dorsum of the foot; some are simple openings, others are raised upon soft elevations, or present a pouting edge. The appearance of the more recent, especially in preserved specimens, is characteristic, being circular in form, from one-third to one-half inch in diameter, and gradually deepening towards the central aperture from the removal of successive layers of cuticle; white patches are frequently seen around; the size of the foot, its globular form, and the number and appearance of the sinuses being the chief diagnostic characters, to which may be added the absence of a corresponding degree of constitutional disturbance, pain, or hectic fever. The patients generally have a scrofulous, or syphilitic taint. But there is one test which is applicable to almost all cases, and that is, the character of the discharge. Sometimes the fungus particles are so abundant as to block up the apertures of the sinuses, or float away in numbers in the thin serous or sero-purulent fluid, and when less numerous they may generally be detected with the aid of a lens. In the black variety a single glance will be sufficient, and in the pale and soft (which have been well compared to mustard, or poppy seeds) their appearance is hardly less characteristic. The presence of these particles in the discharge from the sinuses is an infallible test of the nature of the disease, and by the use of the microscope we are early enabled to make a correct diagnosis. The external appearances of mycetoma appear to be the same whatever the form of pseudo-growth; the sinuses are the terminations of canals more or less lengthy and tortuous, which occasionally lead to bone; but the latter will not usually yield to pressure of the probe, for it is not really in a carious condition, although partly absorbed.

A section of a foot thus affected presents on first view much confusion of parts. The skin is greatly thickened, and the bony, muscular, and fibrous tissues seem blended and intermixed with a glairy or tenacious slough-like material of reddish or blackish tint; globular masses of fungi, too, are seen scattered about, which are either yellowish and of cheery consistence, or deep brown or black, and much firmer.

The collections of fungi are lodged in spherical cavities, hollowed out in the osseous cancellous tissue, or in the soft parts, from which "loculi" branching tubular canals pass off, frequently inosculating, and terminating either in closed expanded extremities, or on the surface at the sinus apertures. These canals, like the loculi, are lined throughout by a membrane, easily separated from the bone, or blended with the softer tissues; and they also contain fungus particles embedded in the soft or glairy material above-mentioned. It is evident that their office is to conduct the fruits of the vegetable parasite to the external surface, where they are expelled in the serous discharge. A varying amount of inflammation, with its results, attends the growth of these foreign bodies, and the bones of the foot and leg, or of the hand, are affected in a striking manner; the spherical cavities which they contain are the most peculiar feature, and caries, or ulceration of the articulations is seldom present, absorption from pressure being the only agent at work.

The ordinary duration of the disease is prolonged. The cases seen vary from four to ten, or even thirty years' standing, and its termination seems only coeval with exhaustion of the vital powers. Some idea of the frequency of this unique affection may be gained from the fact that individual observers in this country (India) reckon their cases by the score. In Bombay a year seldom passes without three or four cases being seen at the Jamsetjee

(a) "On Mycetoma, or the Fungus Disease of India." By H. Vandyke Carter, M.D. Lond., of H. M.'s Indian Army. Churchill. 1874.

Jejeebhoy Hospital, although the disease is not endemic here. It has only been seen in natives hitherto, the explanation of which is that they go about bare-footed, and seldom wash the feet thoroughly. Other noteworthy features are the following: It has mostly a local manifestation; it is much more frequent in men than in women, and during the middle periods of life, and commonest among the agricultural classes; it is not hereditary, or peculiar to any diathesis; and is unlike a scrofulous affection, leprosy, or elephantiasis."

Our sketch of the disease is necessarily brief, but sufficiently comprehensive to make our readers acquainted with its general characters. Dr. Carter, as we have already intimated, describes two varieties of mycetoma—a pale and a dark—with two forms of discharge, and in common with other observers, has met with cases in which no evidence of a fungoid growth could be detected. Case 6, page 11, is a case in point—a Hindoo woman whose right foot was affected by a soft variety, and "the peculiar roe-like masses, quite beneath the skin, were at once examined under the microscope, and no fungus particles were discovered." This is by no means a solitary instance, and while the full details given evince a laudable desire to conceal nothing, they serve to give colour and strength to opinions expressed by other trustworthy investigators, who have hitherto failed to discover "fungus particles," (a) and in the words of the author, "become acquainted with any facts which would even suggest the idea of an infection of the whole system by entophytal spores." The author, however, asserts "that the foot disease of India is not a carious, strumous, myeloid, or any like affection, but a veritable parasitic disease, due to the growth and extension within the tissues of the human foot of an indigenous mould or fungus of a true plant nature." Dr. Carter be-

lieves, and is supported in this view by an eminent mycologist, that the fungus belongs to a peculiar and undefined species, although we notice recently a modification of his views in the pages of a contemporary (*Lancet*, July 11th, p. 44). He there writes: "The nature of the parasite is not now so much insisted upon as its presence; and the question is especially considered whether such foreign organism is not the sole proximate cause of a tumour (often large in size) of the foot or hand." Space will not permit us to follow Dr. Carter throughout in his arguments in favour of these views, and we must content ourselves by making a few remarks on the relation said to exist between the parasitic growth and the phenomena of disease in the foot. In the first place, we are free to confess that we do not quite see how the minute spores of a plant can penetrate and take root in the hard resisting structures of a hand or a foot, there germinate, and become developed into forms so entirely abnormal as those figured; and having completed the work of destruction amongst the soft and hard tissues, find their way once more to the surface, through sinuses and canals of their own making, rather than continue a damaging course in a soil at once congenial and in every way suited to feed upon. Certainly such a selecting parasite transcends our previous experience of analogous organisms. It is curious to observe also the power of selecting one foot or limb rather than the other, the right foot or the right hand; it gives a preference to the male sex rather than the female in a country where the feet of both sexes are equally exposed to the poison. In exceptional instances fungus forms no part of the diseased mass. At page 9 we read the examination of a foot gave negative results—"only red grains, like Cayenne pepper, crystalline bodies, and oil globules were found; nevertheless, from these bodies a red mould was grown." In another specimen, preserved in spirits, mould was successfully cultivated when sown on rice paste; and remarkable enough, the mould observed to be developed under these varying conditions was identified as one and the same kind of fungus. It is scarcely possible to believe that fungus spores preserved in spirits retain their vitality.

Indian medical men who have seen a great deal of Madura foot disease do not concur with Dr. Carter as to its "symmetrical and consentaneous character." Dr. Collas, for instance, says: "By the expression endemic degeneration of the bones of the foot, I mean a localisation in one foot of a benign diathesis, which develops itself in a marked manner, more frequently in men than in women, and is characterised by the production of a peculiar element, which, occupying the place of the bones of the foot, ends by inducing their destruction. It is impossible that this malady can be anything else than a tumour, of which the pathological element is made up of myeloplaxes, produced by a diathesis *sui generis*, and by hypergenesis, i.e., in a proportion much exceeding that encountered in the substance of the bones in a normal state." It is quite clear then that Collas does not look upon the fungus, when present, as the proximate cause of the disease, but rather as an incidental attendant on a pre-existing or contemporaneous morbid process.

Some discrepancy of opinion also seems to prevail among observers equally competent to interpret the microscopical characters of abnormal products. Portions of a Madura foot were submitted by Dr. Ballingall to the late Professor Quekett, and he entirely "failed to come to any definite opinion of their character." Cohn, Moxon, Cunningham, Lewis, the editor of the *Indian Medical Gazette*, &c., have been equally unsuccessful in the detection of fungus particles. Dr. Carter's explanation of this is, that at a certain stage of the disease, "its characteristic structure is lost, the fungi having undergone transformation, and become a nucleus of crystallisation." Mr. Hogg, in a paper contributed to the "Royal Microscopical Society Transactions," June, 1871, says: "A prolonged and careful microscopical examination only gave negative results, so far as fungi were concerned, and a chemical analysis of the 'fish-roe-like bodies' yielded only 'fatty

(a) So lately as October last we observe in *The Indian Medical Gazette* the particulars of a typical case of Madura-foot disease. The brief history, given by Dr. Cleghorn, of Allakabad, under whose care the patient came, is as follows: "A Brahmin, aged 45, residing in a village in Gwalior, by occupation a cultivator, first noticed a small swelling on the upper surface of the left foot. No suspicion of guinea worm, injury, or other exciting cause. The chowkidar of the village, who had lately come from another zillah, had a similar swelling of the foot, but no permanent resident of the village was affected."

"The foot presented the following appearance: The swelling commenced rather abruptly over the first row of tarsal bones, gradually increasing till it assumed an almost globular form near the distal half of the metatarsal bones. It was more rounded and protuberant on the plantar than on the dorsal aspect of the foot; the first two phalanges of the toes were absorbed into the swelling; the whole surface, more particularly the dorsal, was studded with well-defined elevations, oval in shape, varying in size from a split pea to a four anna piece; the skin in the centre of these elevations was thinned, but no breach of surface was detected; pain was not a prominent symptom, the patient simply complaining of a dull heavy feeling in the part. The foot was removed at the ankle-joint by Syme's operation, with a successful result."

The following were the appearances observed on dissection:—

"The projections on the surface contained dirty purulent matter and numerous roe-like bodies; the soft tissues of the foot on longitudinal section appeared as a dark coloured disorganised mass, containing irregular shaped cavities full of dirty coloured pus and roe-like particles; there was no tunnelling, such as is described in Aitkin's 'Practice of Medicine'; the black matter did not extend posteriorly beyond the first anatomical row of tarsal bones, and the disease was limited by a well defined margin, which, though irregular, did not blend with the prolongations into the contiguous healthy tissue. The blackened disorganised tissues adhered firmly to the periosteum, but the bones and cartilages of all the joints appeared to be perfectly healthy."

"Numerous microscopical examinations were made of the black matter, the roe-like particles, the purulent fluid, the textures contiguous to the diseases, the cartilages, and the cancellous texture of the bones, but no fungus elements were found. On boiling portions of the black mass in liq. potassæ, and teasing them with needles, mycelial looking fragments were noticed on two occasions, but these were understood to be due to splitting of the fibrous texture. Large fat cells of uniform size were in great excess and seen everywhere, and in appearance were not unlike the spores freed from their contents, depicted in Aitkin's 'Practice of Medicine,' in the article treating of this affection."

matters, phosphate of lime and iron, carbonate of lime, and some organic matter, albumen or fibrine." Mr. Berkeley, whose opinion strongly favours Dr. Carter's views, writes: "The little granular bodies are so closely involved in stearine that their germination is scarcely possible."

Certainly the earlier drawings of the fungus particles, serve rather to increase a distrust felt as to the fungoid nature of mycetoma than otherwise. It is impossible to conceive anything more misleading than the figures that accompany an early paper published in the *Intellectual Observer*, while the drawings in the "Pathological Society's Trans." are scarcely less creditable, or likely to clear up a difficulty. Dr. Carter, however, now makes ample amends for the shortcomings of those who failed in their attempts to represent *Chionyphe Carteri*; but withal, we venture to think that, on reflection, our author will scarcely insist that he has conclusively established the parasitic nature of the Madura foot disease of India. The exceptionally small proportion of fungus particles in any of the specimens we have examined point to but one conclusion—that the fungus must have been an extraneous growth subsequently and accidentally introduced into the diseased mass. We, however, unhesitatingly affirm that Dr. Carter, by the publication of this monograph, has done good service to the profession. His book throughout bears ample evidence of an immense amount of pains-taking research to clear up the more obscure points of the disease, and to him we look for a more extended knowledge of a remarkable affection which "is not carious, strumous, or myeloid, but a veritable parasitic disease."

We must add that Dr. Carter's volume is a valuable and handsome contribution to medical literature, and will amply repay perusal.

## EPIGRAM.

### DE CREMATIONE.

Ἐν δὲ πυρρὶ θανάτῳ νεκρὸν θέσαν, ἀχόμενοι κῆρ.  
*Iliados* xxiii. l. 165.

CHIRURGUS quidam exuri vult omne cadaver,

Ut cito, quod vermis tardius, ignis agat.

Hic querit semper lapidem, æternumque requirit—

*Calculus* est hodie; in sucla—cenotaphium.

### CREMATION.

THOMPSON to burn our corpses would persuade us,

To promptly pay the elements that made us;

The lithic Surgeon's aim is clearly shown—

Alive, a calculus; defunct—a stone.

W. BOYD MUSHET, M.B. Lond.

## Medical News.

**University of London.**—The following is a list of the candidates who passed the recent second M.B. examination:—

### First Division.

Braunfoot, Henry Seymour, Guy's Hospital.

Crocker, Henry Radcliffe, University College.

Duncan, Andrew, King's College.

Duncan, Peter Thomas, University College.

Eastes, Thomas, Guy's Hospital.

Gould, Alfred Pearce, University College.

Harris, Vincent Dormer, St Bartholomew's Hospital.

Nicholson, Arthur, King's College.

Rigby, James Arthur, Guy's Hospital.

Sturge, William Allen, University College.

Whittle, Edward George, University College.

### Second Division.

Ashby, Henry, Guy's Hospital.

Boach, Fletcher, King's College.

Briggs, George Chapman, King's College.

Davies, David Arthur, University College.

Houghton, Walter Benoni, University College.

Morley, Thomas Simmons, Guy's Hospital.

Moss, Herbert Campbell, King's College.

Percival, George Henry, Guy's Hospital.

**Astley Cooper Prize.**—The next triennial prize of £300, under the will of late Sir Astley Cooper, Bart., will be awarded to the author of the best essay or treatise on "The Anatomy, Physiology, and Pathology of the Sympathetic Nervous System." The condition annexed by the testator is, "That the essays or treatises to be written for such prize shall contain original experiments and observations, which shall not have been previously published; and that each essay or treatise shall (as far as the subject shall admit of) be illustrated by preparations and by drawings, which preparations and drawings shall be added to the Museum of Guy's Hospital, and shall, together with the work itself and the sole and exclusive interest therein and the copyright thereof, become henceforth the property of that institution, and shall be relinquished and transferred as such by the successful candidate." And it is expressly declared in the will "that no physician, or surgeon, or other officer for the time being, of Guy's Hospital or of St. Thomas' Hospital, in the borough of Southwark, nor any person related by blood or affinity to any such physician or surgeon, for the time being, or to any other officer for the time being in either of the said hospitals shall at any time receive or be entitled to claim the prize." But, with the exception here referred to, this prize is open for competition to the whole world. Candidates are informed that their essays, either written in the English language, or if in a foreign language, accompanied by an English translation, must be sent to Guy's Hospital on or before January 1st, 1877, addressed to the Physicians and Surgeons of Guy's Hospital. Each essay or treatise must be distinguished by a motto, and be accompanied by a sealed envelope containing the name and address of the writer. None of the envelopes will be opened except that which accompanies the successful treatise. The unsuccessful essays or treatises, with the illustrative preparations and drawings, will remain at the Museum of Guy's Hospital until claimed by the respective writers or their agents.

**The Hospital Saturday Fund**—At a meeting of the Council, on Saturday last, it was finally decided, after discussion, that the Report be circulated amongst the members, and be considered on the 9th proximo. In it a description was given of the various agencies employed on the 7th October, and the respective results. A number of boys were stationed with boxes in various public thoroughfares; and on Hospital Saturday several tables, presided over by ladies and gentlemen, were placed in the streets for the purpose of receiving public subscriptions. A sum of £258 14s. was obtained by the latter means at a cost of something over £30. The employment of the boys was not so successful, only £60 being collected, and the expenditure in wages and uniform, being more than 50 per cent. A portion of the money spent in printing subscription cheques was also thrown away, for this mode of collection proved unsuccessful. As the whole of the boxes have not yet been collected, the amount received by this means cannot be stated, but the average so far is about 7s. per box, collected at a cost of about 2s. each. A sum of £300 was raised for the fund by the performances given at Drury Lane, Adelphi, and the Princess's Theatres, and £75 by the promenade concerts at the Agricultural Hall; out of this, H.R.H. the Duke of Edinburgh gave £25. So far the total contributions barely reach £8,000, and the expenses will not fall short of £1,500. Some members of the Council deplored the paucity of contributions from the working classes; but this was attributed to the fact that they were of all others, the most suspicious, and would not, until they were satisfied with the *bonâ fides* of an undertaking, give it their support. We wonder how long it takes to satisfy the masses of the *bonâ fides* of hospitals which have been established centuries for their benefit! besides which, the Hospital Saturday Committee have had twelve months to satisfy them upon the point. The fact is, that so long as they can get medical advice and medicine for nothing they will prefer to spend their spare cash in the public-house.

**ASTLEY COOPER PRIZE.**—The next Triennial Prize of £300 will be awarded to the Author of the best Essay or Treatise on "The Anatomy, Physiology, and Pathology of the Sympathetic Nervous System." Candidates are informed that their Essays, either written in the English language, or if in a foreign language accompanied by an English translation, must be sent to Guy's Hospital on or before January 1st, 1877, addressed to the Physicians and Surgeons of Guy's Hospital.

Each Essay or Treatise must be distinguished by a motto, and be accompanied by a sealed envelope containing the name and address of the writer. For further particulars regarding the other conditions to be complied with, *vide* the printed forms, which may be obtained on application at the Hospital.

### A N EARNST APPEAL to CHRISTIAN CHARITY.

A Lady, daughter of an officer, now deceased, but who formerly held a high position in the British Army, and served his country at home and abroad for 54 years, is at present reduced to a state of the deepest distress, with four children, in consequence of the lengthened illness of her husband.

This illness, contracted abroad, has incapacitated him from supporting his family, and obliged him, through dire necessity, to seek refuge in one of the Dublin Hospitals, where he lies at present a helpless invalid.

The deceased Officer referred to was a Doctor in the British Army, and at the time of his death held the position of Inspector-General of Hospitals; his daughter, one of a large family, is precluded from obtaining relief from the Medical Benevolent Fund of Ireland in consequence of being married; whilst her husband is at present a patient in the Adelaide Hospital, and we hope soon to procure his admission into the Hospital for Incurables. For these reasons we ask your kind attention to this appeal. The smallest subscriptions will be received and acknowledged by

M. A. WARD, M.B., 1 Rathmines Road, Dublin.

JAMES WHITE, Rector of St. Thomas's,  
15 Middle Gardiner Street, Dublin

### TRINITY COLLEGE, DUBLIN.—SCHOOL of PHYSIC IN IRELAND.

Pursuant to the provisions of the School of Physic Act, 40 Geo. III., ch. 84, and Amendment Act, 30 Victoria, ch. 9: Notice is hereby given that the Professorship of Chemistry in the School of Physic became vacant on the 3rd of OCTOBER, 1874; and that on SATURDAY, the 80th JANUARY, 1875, the Provost and Senior Fellows of Trinity College will, at the hour of twelve of the clock (noon), in the Board-room of the said College, proceed to elect a Professor of Chemistry, in the room of Professor James Apjohn, resigned.

The Emoluments and advantages of the Professorship consist of the following items:—

- 1st. A fixed salary of £400 per annum.
- 2nd. An additional payment of £100 per annum, on condition that the Professor shall give free Laboratory instruction to such Senior Sophisters as shall be nominated by the Bursar.
- 3rd. Fees for Lectures and Laboratory Instruction, to be regulated from time to time by the Provost and Senior Fellows.

N. B.—The fees as at present arranged are—

Medical Lectures (Winter Course) . . . £3 3 0

Medical Practical Course (Summer) . . . £5 0 0

Laboratory Course (eight months) . . . £10 10 0

Graduates in Arts, and Students whose names are on the College books, are admitted to the Medical Courses on payment of half the above fees.

- 4th. The Professor shall have the use of the College Laboratory for analyses bearing on Medical Chemistry, and approved by the Provost and Senior Fellows, such as Medical and Medicolegal investigations, and analyses connected with purposes of Public Health.

All Candidates are required to send their names, with the places of their education, the Universities where they have taken their Medical Degrees, and the places where they have practised, to the Registrar of Trinity College, Dublin, and the Registrar of the King and Queen's College of Physicians in Ireland, on or before Saturday, the 23rd January, 1875.

Candidates wishing for further information are requested to communicate with the Rev. Dr. HAUGHTON, Medical Registrar, Trinity College Dublin.

ANDREW S. HART, Registrar, T.C.D.

J. MAGEE FINNY, Registrar, K. & Q.C.P.

**EAST LONDON HOSPITAL FOR CHILDREN, and DISPENSARY for WOMEN, Ratcliff Cross, E.**—The office of RESIDENT MEDICAL OFFICER to this Charity is now vacant, and applications are invited for the post. The candidate must be unmarried and a fully-qualified practitioner in Medicine and Surgery. There are 35 beds in the Hospital, and an average attendance of from 100 to 120 out-patients daily. The salary is £60 per annum, with board, lodging, and washing.

Application to be sent to the Secretary at the Hospital on or before Thursday, the 19th inst., at 12 o'clock, who will supply a copy of the rules and any other information required.

ASHTON WARNER, Secretary.

## MALVERN COLLEGE.

This COLLEGE contains TWO DEPARTMENTS—the CLASSICAL and the MODERN. There is also a Preparatory LOWER SCHOOL. There are Boarding Houses within the College Grounds, held by the Head Master and others of his Staff; a Gymnasium, &c.

Board and Tuition under 14, £80; over 14, £90. Non-shareholders pay an extra fee of £6. Special advantages for Sons of Clergymen and Home Boarders.

For further information apply to the Rev. ARTHUR FABER, M.A., Head Master, late Fellow and Tutor of New College, Oxford.

The Examination for Scholarships and Exhibitions on December 22nd and 23rd.

### DUBLIN INFIRMARY for DISEASES of the EYE and EAR, Ely Place.

Ophthalmic and Aural Surgeon:

ARCHIBALD HAMILTON JACOB, M.D. Dub., F.R.C.S., Ex-Ophthalmic and Aural Surgeon to the City of Dublin Hospital.

Consulting Physician:

EVERY KENNEDY, M.D. (Hon. Caus.) T.C.D. and Edin., Fellow and Ex-President King and Queen's College of Physicians.

Consulting Surgeon:

GEORGE H. PORTER, F.R.C.S.I.; M.Ch. T.C.D. (Hon. Caus.), Surgeon in Ordinary to Her Majesty the Queen in Ireland; Fellow and Ex-President, R.C.S.I.; Senior Surgeon to the Meath Hospital.

Obstetric Physician:

JOHN CRONYN, M.D., F.R.C.S., Examiner in Midwifery, Roy. Col. Surgeons; Ex-Assistant Physician Rotunda Hospital.

### Work, Income, and Expenditure for Twelve Months, ending June 30, 1873.

Annual number of Dispensary patients	...	...	...	5,847
Number of visits paid by such patients	...	...	...	124
Number of patients within the Infirmary	...	...	...	163
Number of operations performed	...	...	...	£37 15 0
Total gross expenditure per bed per annum	...	...	...	1 10 6
Average expenditure per intern patient	...	...	...	

The Infirmary is wholly dependent on private benefactions, and is in debt to the Medical Officer. SUBSCRIPTIONS ARE EARNESTLY REQUESTED

### THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H. THE PRINCE OF WALES.

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation. Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office,

40 MOLESWORTH STREET, DUBLIN,

W. O'NEILL, Secretary.

### BUTLER'S MEDICAL HALL, 53 & 54 LOWER SACKVILLE STREET, DUBLIN.

ESTABLISHED A.D. 1817,

or Compounding Prescriptions and Supplying Genuine Medicines, is conducted, as formerly, under the careful superintendence of

WILLIAM STARKEY, M.D.,

Licentiate Apothecary,

# The Medical Press & Circular.

### A Course of Lectures

ON THE

#### NATURE AND TREATMENT OF DEFORMITIES OF THE HUMAN BODY,

DELIVERED IN THE MEATH HOSPITAL, DUBLIN, BY  
LAMBERT H. ORMSBY,

Surgeon to the Hospital, and Demonstrator in the School of Surgery  
Royal College of Surgeons in Ireland.

LECTURE VIII. (*continued from page 415.*)

#### DEFORMITIES OF THE JAWS.

THE consideration of the deformities of the face would not be complete without making some allusion to the above. Tumours affect both the upper and lower jaw alike, and when of a large size produce perceptible deformity. To enter into the consideration of the consistence and character of the various tumours seen in the upper and lower jaw would be far beyond the limits of these lectures, and I will merely content myself with mentioning by name the most important—viz, 1, Osseous; 2, Vascular; 3, Fibrous; 4, Sarcomatous; 5, Enchondromatous; 6, Cystic; 7, Mucous Polypi; 8, Carcinomatous; 9, Melanotic; and 10, Myeloid Tumours.

These comprise nearly all that are met with, and occasionally attain an enormous size, giving the person a most hideous and revolting appearance. Tumours are also found springing from the alveolar process of the upper or lower jaw, termed epulis, and they either grow between or from the stump of a decayed tooth or teeth, implicating the osseous walls of the jaw, and is divided into two varieties, the simple or benign, and the malignant or cancerous. These are merely mentioned for the sake of the deformity they produce, and the treatment does not

differ materially from the treatment of tumours elsewhere. The simple is a fibrous tumour, and is removed by excision, taking care to remove the tumour in its entirety, or it will likely return. The malignant requires the same treatment, but a great deal more of the parts have to be removed, as the jaw is much more extensively implicated. Next in frequency, producing deformity, are the various changes that take place in the jaws, either due to inflammation, abscess, periosteal thickening, or necrosis, which is a disease that nearly always causes the face to assume a permanent swollen and deformed condition; the general assigned causes are—blows, salivation from mercury, exposure to the fumes of phosphorus in the manufacture of lucifer and other matches; again, it has occurred idiopathically, where no cause whatever could be ascertained for giving rise to the disease. Necrosis may destroy the whole jaw, or in part, and the treatment here does not differ from the treatment of necrosis elsewhere, except that any operative procedure for the removal of dead bone must be so performed as to leave behind as little deformity as possible, and any sequestrum to be removed should be extracted from the inside of the mouth, if possible, which, however, is not in all cases an easy matter. The next deformities we will consider are due to enlargements of the antrum, which may arise from an accumulation of fluid, either consisting of—1. A glairy mucus, something like what is contained in a ranula, commonly called dropsy of the antrum; or it may be due to—2. Suppuration, and contain pus; 3. Or it may be due to some tumour or abnormal growth arising from the walls of the cavity. Whatever it may be, the walls of the antrum very soon bulge out, and become prominent and perceptible externally, the patient complaining at the same time of dull aching pain, attended with occasionally throbbing, perhaps rigors and fever, and it may so bulge internally towards the nostril as to stop it up, and prevent air to pass through, or to pass with difficulty. This deformity can be easily removed by timely operation and judicious treatment—viz, the removal of either the bicuspid or molar tooth corresponding to the inferior part of the antrum, and pushing a strong trochar or stout pair of scissors through the empty socket of the tooth removed up into the floor of the cavity: the matter will soon be thus

evacuated, and the antrum should then be syringed out with warm water.

We now come to the various tumours and growths before mentioned arising from the jaws, which are numerous and important, inasmuch as they produce distressing deformity, and their complete removal requires perhaps more skill and patience and anatomical information than any other operation in the whole scope of surgery. And for an accurate account of the various tumours of the jaws—the diagnosis, prognosis, and operative treatment of such, I refer you to the most instructive and elaborate work I know on the subject, written by Mr. Christopher Heath, (a) in which work you will see a great number of faithful woodcuts depicting the various forms of growths, and also the hideous and distressing appearance the face assumes from the consequence of such abnormal enlargements.

#### CLOSURE OF THE JAWS.

Such cases are occasionally met with, quite independent of Trismus, or *locked jaw*, as a symptom of tetanus, which, as a matter of course, requires a separate consideration, and is therefore beyond the limits of this work. Mr. Heath mentions that spasmodic closure of the jaws is nearly always caused by eruption of the wisdom teeth in the lower jaw, owing to want of room between the second molar tooth and the ramus of the lower jaw; the pressure which it exerts produces irritation to the parts surrounding, setting up tonic spasm in the masseter and internal pterygoid muscles, which keep the jaws spasmodically closed.

The spasmodic closure is met with at about the time the last molar tooth makes its appearance, and generally passes away when its complete eruption has taken place and the irritating causes removed. The jaws, however, may be divaricated by a screw gag, or, under chloroform, to forcibly separate the jaws asunder, and insert a wedge of wood, or other hard substance. Dental surgeons recommend the extraction of the second molar tooth, or, if the last can be reached, to remove it instead. Closure of the jaws, or inability to open the mouth to its full extent, may come on from inflammation and abscess of the gum.

Permanent closure of the jaws is of a still more important nature to the practical surgeon than the preceding, as it generally arises from a different set of causes, such as—1. Sloughing of the cheek, the result of cancrum oris; 2. Profuse salivation; 3. Inflammation and adhesion of the gums, with portion of the cheeks, after operation for removal of necrosed bone; 4. From wounds of the cheeks or other traumatic causes; 5. Disease and impairment of the temporo-maxillary articulation, ending in false or true ankylosis; 6. The immobility may be caused by a bony ridge or osseous band connecting the lower jaw with the upper.

Permanent closure of the lower jaw, then, will be found more frequently to arise from—1. Contraction, adhesion, and cicatrization of the substance of the cheek, within or without the mouth, consequent on sloughing of the tissues in cancrum oris, and burns or other traumatic causes. 2. From change in the temporo-maxillary articulation, producing either true or false ankylosis. In either form there is at times complete closure of the jaws, so much so that neither patient nor surgeon can separate them, even when considerable force is applied.

For permanent closure of the jaw, for the first set of causes, simple division of the contracted soft tissues and the masseter has been often performed; but contraction comes on again, and the jaws in some time are closed nearly as bad as before. Professor Esmarch, of Kiel, recommends an operation which consists in removing a wedge-shaped piece of the lower jaw in front of the insertion of the masseter muscle, say a piece measuring a quarter of an inch on the upper margin and half an inch on the lower margin. This is done at one side, and enables that half of

the jaw to be separated from the upper, although the other side remains still in its abnormal position. Professor Rizzoli, of Bologna, proposed an operation for simple division of the lower jaw, to effect the same object, from the inside of the mouth, and not requiring any external incision at all. This division was made with a powerful bone forceps. This operation labours under the disadvantage of not being permanent, for the bone unites at the seat of division, and the case becomes as bad as ever. Full information of these operations is given in Mr. Heath's work on the jaws.

#### ANCHYLOSIS OF THE LOWER JAW.

True, or osseous ankylosis, is very rare, although cases are recorded as having occurred from time to time, and of complete osseous union of the lower jaw to the temporal bone. In Guy's Hospital Museum there is a skull of a negro who had complete osseous ankylosis of the temporo-maxillary articulation.

The history of such cases are necessarily very obscure, and few are ever recognised until the osseous union is found to be completed, and then treatment seems to do very little for such cases unless something very heroic is put into practice. However, a mild attempt ought to be made to try and relieve and remedy the deformity, endeavouring to set up passive motion with gags and wedges, and gradual force applied for the purpose of opening the jaws is recommended; but it is found that the jaws become just as closed as ever when treatment is relinquished; dividing the ramus through the mouth as high up as possible with a bone forceps and establishing a false joint; the neck of the jaw has been also broken with a chisel and hammer, and a false joint established, and is recorded as being successful.

*False Ankylosis*, or fibrous adhesions about the joint, is of more frequent occurrence than the preceding; it comes on from a variety of causes, among which I may mention cold, scrofulous disease, syphilitic synovitis, and chronic rheumatism. Arthritis may come on after fever, scarlatina, measles, and acute rheumatism, and in some cases stiffness occurs in this joint without any assignable cause. I had a very successful case under my care in the Meath Hospital, of a little boy, set. 10, of very healthy-looking appearance, who had his jaws closed for two years; the teeth were as close as possible, and the only way he could take nourishment and feed himself was by an interval that was made by the loss of some teeth in the upper and lower jaw, and he could not chew any solid food, and had to merely be satisfied by taking fluids by suction, or, if any solid food, it had to be mashed, or cut up very finely. He had been subjected to a variety of treatments before I saw him, but the stiffness and immobility did not disappear. After admission into the hospital I made a careful examination of the jaws, and found although the jaws were so tightly closed, when they were grasped firmly by the hand, and an endeavour made to set up movement, a slight yielding was perceptible. I then determined to put him under chloroform, which I did, and with some force I separated the jaws nearly a quarter of an inch. I then inserted the blades, armed and covered with lint, of a screw gag, and when inserted well between the teeth I turned the screw, which had the power of divaricating the blades. On that occasion I was not anxious to accomplish all in the one operation, but inserted a small wedge of soft wood between the teeth, when I had separated the jaws a little more by the motion of the screw, and put the lad to bed, ordered a nice saline purgative draught, and a cold evaporating lotion to be applied on lint behind and below the ears, over the temporo-maxillary articulation. On the next day after the operation there was not much inflammation or pain present, and on the third day I applied the gag again, and separated the jaws still more, and at intervals of three days to a week I attempted separation with the gag, so that at the end of six weeks I had the jaws completely separated, so as to enable him to eat solid food and chew with the greatest ease, and since that time I have heard of him being perfectly well. The reason I took my time about the case was to prevent

(a) "Injuries and Diseases of the Jaws," being the Jacksonian Prize Essay of the Royal College of Surgeons of England, 1867. By Christopher Heath, F.R.C.S., Surgeon to University College Hospital, &c. London: J. and A. Churchill, 1872. Second Edition.

any likelihood of extensive inflammation arising due to tearing or sudden breaking up of the adhesions, which would stop all treatment for the time. The child's mother could not give any reason as to the cause of this closure, except that one day, about two years ago, he knocked his chin against a desk at school, but did not complain of any pain at the time, and since that the stiffness came on gradually.

## CHOLERA: ITS ÆTIOLOGY, CONTAGIOUSNESS, AND TREATMENT.

By WM. BOYD MUSHET, M.B. Lond., M.R.C.P.,

Late Physician to the North London Hospital for Consumption, formerly Resident Physician at St. Marylebone Infirmary.

### ÆTIOLOGY.

(Continued from page 371.)

Most authorities agree that cholera cannot become epidemic except under certain conditions of the atmosphere. Dr. Gavin Milroy, Sir Thomas Watson, Dr. Bastian, and Professor Maclean admit an epidemic constitution. We can no more clearly explain why cholera should be, or be not epidemic, and why its epidemic features vary, than why typhus, small-pox, scarlet fever, measles, and influenza should be periodically epidemic, and alter so greatly in prevalence and severity. Why does scarlatina epidemically assume a malignant type? Why does it more greatly prevail at special seasons? Why did measles appear about the eighth century? And why do diseases at times assume a peculiar character, as during the "furunculoid" epidemic nearly two decades since? Scarlatina is always more or less rife, but is not malignant; diarrhoea always is more or less prevalent, but not cholera. Is there any pathognomonic or diagnostic feature, or line of demarcation, to distinguish diarrhoea from premonitory cholera? Diarrhoea graduates imperceptibly into the most malignant forms of cholera. Cholera may be sporadic, slightly or severely epidemic, or almost pandemic—analogueous to other diseases which equally vary in intensity, but are specifically identical. Thus, measles may be *mild* or *black*; scarlatina mere indisposition or a pestilence; small-pox may be discrete and *benignant*, or *malignant* and hemorrhagic. Fever even may be comparatively mild, or accompanied with buboes and sloughing, even in England, and it may assume almost the characters of plague. Cholera and diarrhoea differ in degree in intensity, but they must be held to be, in my opinion, fundamentally and pathologically the same disease. The profession indirectly confesses the identity of diarrhoea and cholera, as ordinary cases of diarrhoea are denominated English cholera, and in the *Lancet* (September, 1854) the necessity of calling every case of diarrhoea cholera is imperatively insisted on. The Committee of the Board of Health, also in the same year, considers that "when cholera and diarrhoea prevail together epidemically they are (with differences of degree) the same disease." In returns of deaths from cholera, deaths from diarrhoea are always included and placed side by side. Why is this if the affections are distinct, and diarrhoea is unconnected with cholera. Does not one practitioner call many of the severer forms of diarrhoea cholera, which another designates choleraic diarrhoea? It is said that cholera may, and does kill, without the supervention of diarrhoea, and that the latter is only a local pathological expression, or anatomical character, so to speak. Dr. MacLoughlin believes such cases to be mythical, and they are, to say the least, infinitely rare, and there is no authentic case, I believe, where the stomach and intestines have been found free from excretions, and in which there has been absence of diarrhoea and vomiting from the attack to death.

The theory of a septic animal poison is in accordance with the origin and mode of propagation of the disease, as on what other hypothesis can we explain its appearance in distant parts after the visit of vessels from infected

countries, or its development on shipboard far from any port? May it not, as M. Guérin believes, arise *de novo*? as it originally did in India; and may not the apparent importation be merely a coincidence, occurring at a time when the epidemic influence exists, and is capable of developing the disease in hitherto unaffected quarters? And when appearing in mid-ocean, is it not due to septic matters collected in the confined limits of the vessel, and rendered active by the ship traversing in its passage the epidemic atmosphere which is passing from one continent to another.

Of course, those who affirm that the epidemic is always the result of importation, the product of contagion, or a special invisible zyme, sometimes dormant, sometimes active, equally affirm the absolute non-connection, non-identity of diarrhoea and cholera. With such, although the symptoms in cholera point most obviously to the intestinal tract, the disease is regarded to be the result of a constitutional poison manifesting itself by local effects; whilst diarrhoea is wholly referable to local, not to systemic causes; and they explain the reason of diarrhoea assuming choleraic features by the fact of diseases being frequently modified by the prevailing epidemic, and assuming more or less of its impress and character. But I rather regard cholera as diarrhoea invested with peculiar malignancy from operation of an epidemic influence, as no division can be practically established between simple diarrhoea and the most virulent algide cholera during the existence of an epidemic.

Dr. Charlton Bastian ("Epidemic and Specific Contagious Diseases"), with whose views I coincide, believes that cholera, typhoid, typhus, plague, relapsing fever, influenza, cerebro-spinal meningitis, erysipelas, pyæmia, puerperal fever, glanders, hydrophobia, and syphilis may be generated *de novo*. He also believes that the several (contagious) specific diseases may have at times a spontaneous origin. He utterly rejects the "germ" theory, as there is no evidence of the presence of germs in the blood or other fluids of the body, and the theory demands a belief in the existence of about twenty different kinds of organisms, never known in their mature condition. He thinks epidemic diseases "are caused and propagated by chemico-physical agencies, and not by multiplication of living units."

Mr. Jonathan Hutchinson, too (*Brit. Med. Journal*, Feb. 7th, 1874), after an immense experience, believes that the several hospital plagues—viz., septicæmia, pyæmia, erysipelas, and hospital gangrene are frequently of autogenetic origin, though they subsequently spread by contagion.

During visitations of cholera, numerous cases of severe or choleraic diarrhoea occur and recover—many without treatment—not verging into collapse, explicable by the constitutional vigour of those affected, or by the mildness of the septic agency, or non-existence of sufficient epidemic influence, or a combination of several of these operations antagonistic to the development of the malignant form. It is said that there is greatly increased prevalence of diarrhoea at cholera periods; but are the cases, though doubtless more numerous, apparently augmented in consequence of public apprehension and more frequent application of patients for medical assistance? Cases wherein the algide symptoms appear to be almost unpreceded by premonitory diarrhoea are to be explained by the antecedents of the patient, as age, exhaustion, privation, &c., rendering him peculiarly prone to the reception of the poison, which, on such occasions, may be of profound malignity and intensity.

In a large proportion of cases, and even during a local outbreak of cholera, impurity in the water may be adequate to explain the propagation of the disease, but it is altogether inefficient to account for the origin, the *causa causans* of the pestilence. Water only proves a source of disease when loaded with animal impurities, under which circumstances it acts by introduction of septic materials into the system during the persistence of the epidemic influence.

With reference to this point, Dr. Sutherland observes, in his Report to the Board of Health in 1854, that "it is believed by some, that the water which induces cholera

contains the specific poison of cholera in it, probably derived from the evacuations of cholera patients; while others believe there is no sufficient evidence of this being the case, and they consider all the facts go to prove that water containing putrescent organic matter acts as a very powerful predisposing cause of the pestilence in a similar way as does putrescent organic matter introduced into the system by the atmosphere or by food, but not as a specific poison." In a like manner, recent disclosures advise us that vitiated milk may be a vehicle of septic poison.

According to such testimony, cholera requires *two* factors for its generation—viz., septic material *plus* the epidemic influence. This latter, the epidemic influence, seems to be indispensable in the causation of the disease, as dirt, filth, and overcrowding are inoperative *per se*, otherwise cholera would be a constant, not an occasional scourge. On the contrary, zymotic diseases, though varying in prevalence, are never altogether absent from the community. This epidemic influence, physically inappreciable (?) appears to be only active in the vicinity of centres of putrefaction. It would appear to be a meteorological or atmospheric condition, itself variable in energy, even when existent, diffusible according to the direction of the winds, temperature, &c.

The disease is most rife, most malignant, in situations where there is greatest aggregation and evolution of septic animal matters, low level and stagnation of the atmosphere almost invariably contributing to intensify their operation. After a time, the epidemic influence may be dissipated or exhausted, but it appears to be capable of continuance or continued generation, as cholera is reported to be endemic in the Delta of the Ganges, and also amongst the Russian troops in the Caucasus.

The history of plagues and pestilences obviously establishes their intimate connection with the neglect of sanitary laws, and although there may be requisite a peculiar epidemic constitution of the body or of the atmosphere, disease is unproducible without the presence of filth, dirt, refuse, impure water, organic decomposition, or neglect, defiance, or violation of hygienic measures. Dr. Roupell laid great stress on animal effluvia, defective sewerage, and intramural cemeteries, and Dr. Parkes says, that "cholera is most violent and common in the dirtiest and densest parts of the town, less severe among the English soldiers, and not at all seen in the houses of the English residents scattered about." Mr. Grove concurs that diseases amongst the poor owe much of their inveteracy to the accumulation of effete organic matters about their clothes and persons.

The septic poison of cholera, which is sufficient to produce every variety or degree of symptoms, from simple diarrhoea to overwhelming collapse, does not materially interfere with the sensorium or the muscular apparatus, inasmuch as there is no impairment of the vital integrity, no specific poisoning of the blood. There is no exaltation or exaggeration of nutrition, no increased disintegration of tissue or organic change, as in fever, but a *diminution down to a total arrest of the nutritive operations*; so that there are no deleterious elements in the circulation. At the outset, the irritation of putrescent matters in the alimentary canal is most probably local, accompanied by more or less profuse shedding of epithelium; though later, it is likely that an impression is exerted on the sympathetic nerve of the abdomen, which may secondarily become involved. Dr. Carpenter admits that nutrition, secretion, and other vital processes may take place independent of nervous influence, and the enormous surface of the denuded intestines may passively allow the copious transudation which ensues. Still, the nerves greatly influence secretion, and it is a remarkable fact, that notwithstanding the blood is universally dark in the vessels, I distinctly noted, in two cases of abortion in which the subjects died during collapse, that the hæmorrhage from the uterus was arterial, bright red in colour. The functions of the placenta, which are very active and important, are performed, it will be remembered, entirely without the assistance of the nervous system.

I now pause to discuss categorically the widely disseminated

doctrines of Dr. George Johnson, who occupies a most conspicuous position amongst recent writers on cholera. It is essential, therefore, to be somewhat discursive, and afford a special *résumé* of the views of this physician, with the arguments which may warrantably be urged against the soundness of his conclusions.

According to Dr. Johnson, cholera is the result of a material and portable poison, capable of conveyance from place to place, and of communication from person to person. It may enter through the lungs or alimentary canal.

Water is a main vehicle by which the poison enters the system.

It is absorbed into the blood.

The period of incubation is usually from one to three or four days.

The discharges are a conservative effort to expel the poison and its products, analogous to the eruption of small-pox and the diarrhoea of typhoid fever.

The discharges, when abundant, may be so copious as to kill.

They bear, however, no direct relation to the degree of collapse, and they are not the essential or chief cause of collapse, as collapse and death may occur without discharges, and with but scanty secretion into the bowels.

There is impeded circulation through the lungs, as the pulse is small or absent; there is fulness of the veins and lividity, and, after death, the left side of the heart is empty; the right side, the pulmonary artery, and the large veins distended; the lungs anæmic, light in weight. The explanation is, there is contraction of the minute pulmonary arteries—a primary asphyxia, a secondary apnoea. Dr. Johnson believes the cause of contraction of the walls of the minute pulmonary arteries is the poison in the blood, which acts as an irritant upon the muscular coat of the vessels, and the relative deficiency of carbonic acid in the blood he explains by the fact that the small current of blood through the pulmonary capillaries involves a correspondingly diminished formation of carbonic acid.

(To be continued.)

## REPORT ON SYPHILIS.

By C. R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.,  
Senior Physician to the Metropolitan Free Hospital.

DR. FOURNIER ON TERTIARY SYPHILIS OF THE ANUS  
AND RECTUM.

DR. ALFRED FOURNIER continues his lectures at the Lourcine, as follows (*France Médicale*, October 10):—

I propose to speak to you to-day, gentlemen, about tertiary lesions of the anus and rectum, and those of the anus first of all.

*I. Tertiary Lesions of the Anus.*—Tertiary lesions of the anus are infinitely rarer than those of the generative organs, about which I have spoken in our last lecture. They occur, however, with a certain amount of frequency which commends them to our attention.

Thus, lesions consist especially in accidents of ulcerative form. The gummy form is not observed in the anal region, save in truly exceptional cases.

Some words will suffice for the description of these two orders of accidents, for they present themselves here with their habitual characters, and owe only to the conditions of their position the peculiarities of which I am about to speak.

*1. Ulcerative Syphilitic Affections.*—Ulcerative anal syphilitic affections develop themselves either exactly at the level of the mucous ring of the anus, or more frequently at the level of this mucous ring, at the same time as on the peripheric cutaneous region.

They are here what they are elsewhere, that is to say, ulcerations, more or less hollowed out, more or less extensive, variable in aspect and colour, and presenting

for the most part a yellowish base, or vinous red hue, secreting rather abundantly a purulent sanious matter, which is sometimes striated with blood.

The sole peculiarity they present worthy of remark consists in the configuration they affect. Situated on a dusky region, with convergent radiating folds, they cannot evidently lend themselves to the regularity of form which is commonly observed in them on flat surfaces. They obey naturally the conditions of the ground on which they are produced, and then one of two things happens :

Either they are, when seated on the margin of the anus, of lengthened form, following the direction of the folds of the region. They are more or less extended in surface ; sometimes they occupy a rather considerable portion of the margin of the anus ; more frequently they are reduced to the proportions of a simple fissure, or what is commonly called a *rhagade*. Frequently the parts on which they rest become symptomatically inflamed, and this engorges, thickens, and hardens the anal folds, and transforms them into coarse projecting folds.

In this case, however little extended the ulceration may be, it takes on a wavy form, in this way, that it is alternately raised in prominent eminences and depressed in the furrows between. If, on the other hand, it is more restricted and limited to the bottom of the furrows, it is then hidden by the projection of the nodules which cover it, and sometimes even completely dissimulated by the reciprocal touching of these masses, so as not to be perceived until the folds are forcibly held asunder.

Or, again, seated at the very level of the orifice of the rectum, these ulcerative syphilitic affections form wounds with walls ulcerated and opposed to each other, as is the healthy anal mucous membrane. If the anus be then deprived of its folds, these ulcerations open like the leaves of a book, to return into contact as soon as the sphincter is distended. As supplementary detail, let us add that, in most cases, the ulcerated lesions are accompanied by a certain degree of inflammatory, œdematous, or sclerous swelling of the anal mucous membrane. Almost always in such cases we find the orifice of the rectum surrounded with a series of ovoid teats flattened laterally, as large as a gooseberry, or a white bean, rosy on the surface, and presenting a hardness either inflammatory and pasty, or dry, parchment-like, and elastic, comparable to chancreous induration.

Sometimes one only of these lesions presents itself at the anus ; at other times we notice several of them. We even see in certain cases the whole circumference of the anus converted into one sore by an extensive ulcerating syphilitic affection, or by the fusion of several of these ulcerations, which at first were separated.

It is almost superfluous to say that, on account of their position, these lesions are of an essentially persistent character. Exposed, in fact, to being made unclean by the feces, and to being dragged asunder, distended, and torn by the passage of these matters, they ought to be, and are generally, rather obstinate. We do not succeed in curing them save by using minute care, a careful local hygiene and appropriate dressings. *A fortiori*, these lesions are persistent, and subject to become complicated with inflammatory accidents when they are left to themselves, neglected or irritated by different causes.

These lesions give rise to functional disturbances more or less marked. They are often painful ; they keep up a constant feeling of uneasiness in the region, with tension and heat ; they arouse false desires for defæcation, and sometimes even true tenesmus ; they finally do not admit of evacuation save at the price of rather severe sufferings.

Nevertheless, a double remark ought to be made in this place. In the first place, these ulcerations are generally less painful than one would suppose, *a priori*, from their nature, their extent, their depth, and especially according to their position on the region submitted to alternate relaxation and contraction, on a region where the smallest anal fissure is often the origin of cruel anguish. In the second place, these ulcerations scarcely

ever cause (at least, as far as I have hitherto observed) those spasms so frightfully painful which accompany and characterise the fissure of the anus. These are, then, relatively tolerant ulcerations, if I may thus express myself, not awakening those contractions of the sphincter and those atrocious neuralgic attacks which other anal lesions of less importance sometimes excite during or after defæcation.

2. *Gummy Lesions*.—Gummy lesions are quite exceptional at the anus. I have never observed them, for my part, save from extension to the anus of peripheric gummy ulcerations. Such was, as example, the case of a young woman we had in the wards during the few years past.

This patient presented on the left buttock an enormous ulcerated gummy tumour of phagedænic character. In its strange progress the lesion ended in nearing and then in attacking the anus, and determining there a deep ulceration, which penetrated into the rectum.

Perhaps, however, certain anal lesions which we observe in the condition of ulcerations are but the last phase of gummata, which were at first solid and then ulcerated. I should be tempted to believe this without daring to affirm it, for the demonstration of the fact has escaped me until now.

II. *Tertiary Lesions of the Rectum*.—The tertiary lesions of the rectum are of several orders. They may be ranged under the three following heads : —

#### 1. *Ulcerated Syphilitic Lesions*.

##### 2. *Gummy*.

3. *Ano-rectal Syphiloma*, one of the most curious lesions, and not yet histologically determined in its initial stage, but ending in an advanced stage in the retractile hardening of the walls of the rectum, and thus becoming the most common origin of rectal strictures.

I shall speak but briefly on the two first groups of this lesion. The ulcerative syphilitic affections, in fact, do not present here characters differing from those which they have on other mucous membranes ; and as to gummy syphilitic lesions, they are so rare in the rectum, that it will suffice to mention them. I shall require, in revenge, to insist at length on the recto-anal syphiloma, a lesion as important as it is little known up to this day—a lesion to which there attaches, as you will see, a considerable practical interest.

1. *Ulcerative Syphilitic Affections*.—The rectal tertiary syphilitic affections of ulcerated form are observed in two orders of different conditions.

Most frequently they are confined to the lowest part of the rectum, and are only the intra-rectal continuation of ulcers of the same nature developed upon the anus. Almost always, indeed, we see them co-existing, and confounded with ulcerative anal syphilitic affections. They extend more or less high up the intestine, generally one or two centimetres from the sphincter, more rarely three or four centimetres. In two cases I have seen them passing the limits to which the eye could follow them, even with aid of the speculum, or the valve used by Sims.

It is, then, firstly, incontestable that tertiary ulcerations may exist in the rectum, from the fact of propagation and extension of anal syphilitic affections, and may constitute in the intestine true *intra-rectal* sores. On this first point there is no discussion allowable, and no difficulty.

But the second point is more open to discussion, and more delicate. Do we observe in the rectum any ulcerations which are independent of anal ulcerations ? Do there exist rectal syphilitic affections which are originally and primarily rectal, just as there exist uterine lesions without any connection with vulvar ones ? Well, yes ; lesions of this kind have been recognised ; yes, tertiary ulcerations may at once arise in the rectum, without proceeding by irradiation from anal lesions. Examples of this have been seen, and that in two different orders of cases, namely—1. In cases where the autopsy showed multiple intestinal ulcerations, not only limited to the

rectum, but disseminated in the iliac flexure and the colon. 2. In the cases where the rectum alone was the seat of ulcerations of this nature. These ulcerations, observed several times on living patients, occupied the rectal wall at various heights, most commonly at the level of the ampullar region. They could sometimes be appreciated simply by digital examination, because of their uneven surface, which contrasted with the smooth and velvety surfaces of the neighbouring parts. They become manifest by direct examination in the form of solutions of continuity with irregular edges, with red and bleeding base, partially covered with greyish detritus or adherent mucosity.

But, let us add that, if these ulcerations have an incontestable existence, they are excessively, nay prodigiously rare. They are, I would venture to affirm, quite exceptional lesions. You may believe, gentlemen, that this rarity is more apparent than real, in the sense that people do not always pay sufficient attention to these lesions, or look for them with enough care, and that they have every chance in this way of remaining unnoticed. This is not the case. I affirm to you that, for my part, I have conscientiously sought for rectal syphilitic affections, and that I have met them only in a very small number of cases. Other observers have sought for them without being more fortunate. So that they are hardly referred to in the majority of special treatises.

2. *Gummy Syphilitic Affections.*—More exceptional still than the foregoing are those rectal lesions of gummy form. They have sometimes been spoken of, but without ever any very authentic example being exhibited, with the exception of a case cited by Professor Verneuil. For my part, I declare I have never met with one.

Let us, then, content ourselves with mentioning in its place this kind of lesion, and let us pass on to the study of another lesion, far otherwise worthy on all accounts to fix our attention—namely, the ano-rectal syphiloma.

#### WASTING OF THE TESTES ATTRIBUTED TO IODIDE OF POTASSIUM.

Dr. Lomon (*Gaz. M. de Paris*) gives the case of a young man, set. 27, father of two children, and married, who had, among other symptoms of syphilis, orchitis, and tertiary affections of mouth and pharynx. Mercury was given, and then iodide of potassium in large and increasing doses until healing of lesions. A year after this there was disease of the pharynx, and the patient himself took iodide of potassium in very large doses. He obtained a cure of the ulceration of the pharynx, but after this coarsely made treatment he remarked a notable diminution in his testicles. In the course of a year and some months Dr. Lomon, asked to examine him, found with surprise that the right testis had disappeared, without leaving any trace, and the left was reduced to the size of an almond.

The patient said he had only erections which were difficult to obtain, and painful, although more persistent than before, and that copulation was painful, without any ejaculation.

#### INDIAN MEDICAL NOTES.—No. XXIX.

(FROM OUR SPECIAL CORRESPONDENT.)

MEERUT, October, 1874.

"PRACTICAL" (continued).

ON returning to Meerut, after strolling curiously about the Bazaar, not at all resembling the Burlington Arcade, or the Crystal Palace, or Langham Bazaar, I felt very ill; but it passed off, and next day one could reply, "Not sick, my lord, unless it be in mind." Nor have we leisure to be sick in bustling times. Just now certain complications of fever—for instance, delirium, which induced Oliver Cromwell to pistol two commanders—requires great perpetual tact, when hospital space, resources, and attendants are limited. The old hospitals, one-storeyed double verandahs, mud walls, thatched roof, flagged floors, as long as height

and space and through ventilation were permitted; and, above all things, the latrines so placed as not to be dangerous to the wards; these buildings had, amongst other advantages, no temptation for jumping out of window. The maniac, running along the flat plain, may break his neck at a drain, or drown himself in a shallow tank—yet very rarely. The tendency may be to inflict injury on others. My present most valued attendant not many months ago was fumbling at another patient's throat at night with a knife—soon removed. One man imagined he was in Noah's Ark, and complained of the overcrowding and the smell of the animals. As a rule, sullen, sulky, bombastic, blasphemous, full of grievances, anxious to be off, certain patients are difficult to manage, for the delusions change so capriciously and are so contradictory. One man will lament his *alter ego* dead in India, another be indignant at detention in hospital, the black faces, pun-kahs, surroundings very puzzling. A cunning patient, after long fasting, long coaxing, may open his mouth, take a little nourishment, retained for a minute, then spat in your face. Never hungry or thirsty, he may refuse food for days; neither by the rectum nor the nostril can the waste of tissue be repaired. The temperature of a bath being about 80°—all ice required for drinking purposes—the immersion of burning patients may not reduce temperature at first—may not reduce it at all, nor will the wet sheet invariably answer. Inunction with oil succeeds better than frequent sponging. I am very fond of carbolic oil, keeping off the pestering flies. Ether spray to head and spine—so valuable in many a case in England—may not be available; the rapid evaporation in climate, where also india-rubber appliances, galvanic batteries, certain medicines soon become valueless to be considered. In England also, before shaving the head of a golden-haired beauty, or any bread-winner who cannot afford a wig, you can temporise—not always, for many and many a life may be lost by such consideration. Here, beyond neuralgia, and the look of the thing, there are no objections, the necessity imperative. Bladders of ice to the shaved head, a frequent stream of water down the patient's spine, a hot bottle to his feet, require constant watching, to see these things are done. One night, dropping in accidentally at the hospital, there was a patient 106° in axilla, sleeping—that is, drifting into coma; soon diverted by taking him into the air and scusing the naked body. In the way of medicines, the experience gained at home and abroad, also the teachings of a limited library, lead to the following conclusions regarding India: Chloral, opium, henbane, digitalis, conium by the mouth may do harm in delirium, inducing coma, else aggravating symptoms, if not straining heart, lung, brain, or kidney. Hypodermic injections, friends of my childhood, may play very falsely. Cannabis indica has not been personally tried here; nor did it answer at home. Tartar emetic and opium a good combination. An ancient apothecary, when attacked with fever, locks himself up, lives on this particular remedy, and returns to duty fresh as paint—as good as new. Bromide of potassium may answer, often followed by boils, which the tossing patient turns into ugly bed-sores, difficult to heal. The only suppositories believed in are those of belladonna in substantial doses. Paregoric containing excess of camphor at present is the favourite of the moment, administered by the mouth. Chlorodyne, discarded, is again advancing in favour. Lini-ments of opium, aconite, chloroform, belladonna, and camphor along the spine; beef-juice, egg-flip, wine, or punch, given in quantities dictated by the pulse, breathing, tongue, and urine, all very good—brandy and Madeira specially. At the commencement of delirium a dark room, leeches to the head, blisters to the neck, cotton-wool in the ears, turpentine enema are my weapons, including, if possible, a European nurse—best of all, a comrade who will humour and coax instead of irritating the patient into fiercer delirium, when restrain only increases shouting, heard by other patients, and the muscular contortions, so violent at first, create the more exhaustion. Constant expectoration, frequent micturition, insensibility of

skin, constipation or retention of urine may be followed by prostrating debility, boils, deafness, cuticular hyperæsthesia, paralysis, insanity, or death, when nutrition or digestion fail in a subject who has a constitutional flaw somewhere; and who has not? In a delirium of fever during pregnancy it is obviously almost impossible to adopt the very valuable expedient of cold affusion, or even the wet sheet; still, you can afford great relief to the distended burning abdomen by inunction, which can never be accused of killing the child. The other day a woman, a martyr to fever during pregnancy, had uræmic convulsions, so often dangerous to both. The foetal murmur became hushed, the child fell, the breasts drooped; yet the labour was natural, the infant weak, sallow, premature, four pounds weight—lived a few days. I feared death to mother and child. When children are delirious it is very easy to pop them backwards and forwards into cold water in the early part of the day—not late in the evening, when the water really is too cold for safety. Holding a naked child over a Macbeth caldron of hot water I have found beneficial when skin and kidneys struck work. In the delirium of adults, leeches, blisters, cold affusion, wet sheet, turpentine enemata, sometimes mercurial inunction, alcohol, milk, beef-juice, camphor, opium, and the other remedies are all excellent in their way; but unless you have a good nurse, or, neglecting other patients, do the nursing yourself, at the same time taking the case on its own merits, be most guarded in forming, still more so in expressing, any opinion. Every hour tided over, sleep regained, food digested, pulse, respiration, temperature, urine, excreta—all satisfactory, the patient cheerful, the friends happy, all these things, however, must not shut your eyes to the fact that delirium is very insidious, so apt permanently to damage even the strongest brain.

## Transactions of Societies.

### MEDICAL SOCIETY OF LONDON.

MONDAY, NOVEMBER 9TH, 1874.

Mr. VICTOR DE MERIO, F.R.C.S., in the Chair.

Mr. HENRY SMITH exhibited a tumour removed from a young girl aged 6½ years, to demonstrate the difficulty of diagnosis of tumours. It was situated over the hip-joint, extending down the thigh, and appeared about the size of a man's fist. Three eminent surgeons had seen the patient, and two of them were of opinion that the tumour was cystic, while the third maintained that it was of a solid consistency. Mr. Smith thought at first that it was cystic, but as puncturing with a grooved needle produced no fluid, he concluded that it belonged to the fatty class, and dissected it out from the adjoining tissues. It was adherent to the periosteum over the great trochanter, and was a well-marked instance of fibro-fatty tumour. Its history proved that it should have been removed before, and Mr. Smith had seen several cases of fatty tumour which recurred first in the form of fibroid fatty tumour—i.e., with increase of fibrous element, and lastly, in a malignant form. He wished to know the opinion of the Society as to whether fatty tumours often were followed by malignant ones.

Dr. CLEVELAND and the PRESIDENT having made some remarks,

Mr. WILLIAM ROSE stated that a microscopical examination of this tumour assigned to it a semi-malignant character.

Dr. THEO. WILLIAMS communicated

A CASE OF TRANSFUSION OF LAMB'S BLOOD IN PULMONARY CONSUMPTION, RELATED BY THE RECIPIENT, DR. REDTEL, OF KÖBEN.

The author, who had well-marked tubercular consolidation of the left lung and ulceration of the larynx, accompanied by a certain amount of pyrexia and dysphagia,

was transfused with lamb's blood by Dr. Hesse, of Nordhausen, on the 1st of July, and he narrates his symptoms after the operation. The apparatus consisted of two glass tubes and an india-rubber pipe filled with cold solution of carbonate of soda. By means of this blood flowed from the lamb into the median basilic vein the author for the space of ninety-five seconds. The first sensations were warmth in the arm, formication and redness in the face, and after fifty-five seconds dyspnoea, which became intense, ensued. The operation had to be discontinued at the end of ninety-five seconds. Violent pains in the loins succeeded, which, though they diminished in intensity, lasted some hours, then afterwards assumed a pulsatile character, synchronous with each arterial beat, and were assigned by the author to pressure by the distended inferior vena cava and abdominal aorta on the lumbar sympathetic. Forty minutes after the operation a general rigor, with slight cyanosis appeared, followed an hour later by a reaction and profuse perspiration, lasting for five hours. Pulse 140, resp. 32. The patient slept without drugs, though badly, on account of his cough. On the second day the urine contained a trace of albumen, and five days later the usual eruption of urticaria, accompanied by rather high fever, appeared. This lasted two days, and greatly prostrated him. On the 8th of July some improvement took place in his appetite. The result of the operation appears to have been that no change took place in the symptoms with the exception of the dysphagia. Physical examination showed a considerable diminution of the lung consolidation. Dr. Hesse stated that he regulates the quantity of blood transfused by the patient's appearance and sensations. He has performed the operation thirty-two times with one bad result. He recommends it in cases of phthisis where anæmia is a marked symptom, and especially where the discharge is ushered in by extensive hæmoptysis, accompanied by slight or doubtful physical signs. The pulse is one great indication. If it be full and strong the transfusion is dangerous. Dr. Redtel suggests the use of transfusion of lamb's blood in time of war to supply loss of blood from severe wounds, and stated in conclusion that three weeks after the operation he was gradually becoming worse, having reaped no material benefit from it.

The PRESIDENT mentioned a case that had occurred in the German Hospital, that a patient having lost blood largely through hæmorrhage from caries, a sheep that happened to be on the premises was connected by a simple apparatus like that used by Dr. Hesse, and blood was transfused; the patient, however, died.

Dr. AVELING thought that the objection to the instrument used by Dr. Hesse was the impossibility of measuring the quantity of blood transfused; with Dr. Aveling's instrument there was no difficulty on this score. He preferred human blood to lamb's blood, and stated that he was the first to inject lamb's blood in this country, which he did in the beginning of the present year.

Dr. RICHARDSON then read a paper

#### ON CERTAIN TYPES OF DISEASES INCLUDED UNDER THE TERM PURPURA HÆMORRHAGICA.

He commenced by indicating that in the progress of medical science and art it had often happened that one or more distinct diseases had been discovered to exist under a single generic term. This particularly obtained in respect to the application of the term purpura hæmorrhagica. In the short and practical paper which followed, Dr. Richardson defined three forms of purpuric disease, each having a distinct pathology, etiology, diagnosis, and prognosis, and each requiring a particular treatment. To the forms thus referred to he applied different names, viz.—(1) aqueous purpura; (2) saline purpura; (3) vascular purpura. Aqueous purpura was so named because in it the water of the blood is in excess, and the colloidal and crystalloidal parts are relatively diseased. There is no evidence that the actual quantity of fibrine is reduced, but it is distributed through too large a volume of water. Hence the blood, imperfectly protected by its coagulable fibrine, is ready to flow from the vessels like water from the smallest wound. It is also ready to diffuse through vessels that may be injured by a blow or by pressure. This type of purpura has been studied by the synthetical method, and comparisons were drawn by the author between the blood observed in those researches and the blood of the human subject under the disease in question. The origin of this type of the malady was traced to hereditary causes mainly, but it may arise from mental

shock. Two cases illustrative of this origin were related, in one of which the symptoms came on after fright, in the other after sudden and intense grief. Saline purpura was so named because in it the blood is not surcharged with water, but is surcharged with some saline soluble substance by which the plastic colloidal fibrine is held in undue solution in the water. The synthesis of this type of malady was also explained. The disease is not hereditary, but is induced by some error of diet or other cause that increases the solubility of the fibrine through the blood. The true scorbutic eruptions and scurvy of the old schools of physic come under this head. The author added that he had seen this type of purpura induced by the excessive use of chloral. Much loss of blood is not common in this type of purpura, but passive exudation from vascular parts, as from the jaws, are common with the excess of saline matter. The blood, in fact, will transude from both structures; but after it has passed from the body the fibrine will slowly separate and become pectous. Vascular purpura is a type of the disease in which the blood is not modified at all; the proportions of its water remain the same as in health, but owing to some defect in the vessels of the minute circulation, those vessels allow the blood to escape if they are subjected to any blow or strain or pressure. The nature of the vascular change is obscure: it may be a paralysis of the vessels; but the author is rather inclined to think it due to some actual structural modification of the vessels themselves. The subjects of this type of purpura are usually young, and, as a rule, they present some deformity more or less marked of the skeleton. The diagnosis, differential and general, of these three types of purpura were minutely described, the different characters of the symptoms being defined with especial care; particularly it was pointed out that in the vascular type of the disease the eruption was hard and prominent, from the fact that the blood is natural, the fibrine separates when it is thrown out, and coagulates then. There is sometimes a combination of these types of purpuric disease. Dr. Richardson related a most interesting fact of this nature in the case of a patient from whom an extremely fluid blood flowed from five points on the surface of the body. The paper included finally a review of the special modes of treatment required in each type of purpura that had previously been described. A special point was made of the best method of arresting the hæmorrhage from wounds, as after the extraction of a tooth, in instances of aqueous purpura. In six cases of this kind to which Dr. Richardson had been summoned, to stop what was found to be fatal hæmorrhage, the flow of blood had been checked by the attention paid not less to the general than to the local measures. The general treatment consisted in sustaining the patient with food and administering mineral acids internally, even though the flow of blood were still imperfectly staunched. The local method consists in applying with firm pressure a plastic styptic to the bleeding part; caustic styptics were specially condemned. In conclusion, the value of turpentine for the treatment of the vascular variety of purpura was strongly enforced, and rules for the subject of each type of the disease were specified.

In the discussion which followed the President complimented Dr. Richardson on his useful and convenient classification of purpura, which might lead us to a better knowledge of the causes of that symptom, and to its more scientific treatment. He had seen a well-marked purpuric eruption in a patient deeply imbued with syphilis, and wished to know in what class this instance would be included?

Dr. DALDY had seen several cases of purpura among people living in the low lands near Lewisham, and found it was generally connected with enlarged spleen.

Dr. HARE had seen a most acute case of purpura occur in a man æt. 50, living at Chelsea. At first sight the patient presented the appearance of suffering from glanders. Both face and neck were a mass of extravasated blood patches, which spread afterwards to the body, assuming at first a symmetrical character, but eventually covering the whole body. He died in twenty days from the commencement of the disease, and a cavity was found in one lung, which Dr. Hare considered had something to do with the origin of the complaint.

Dr. CLEVELAND said he had seen purpura occur in patients of all ages—in the child of a few months and in persons over eighty. The worst case he had ever witnessed was one mistaken for malignant small-pox, where blood flowed from every pore, and hæmorrhage took place in the nostrils, bowels, and stomach, soon ending fatally. Though turpen-

tine was good in these cases, he found acetate of lead better than all; and as an instance of Dr. Richardson's third form of purpura, he related a case where a large spot of extravasated blood on one of the limbs was accompanied with aneurism of the aorta, thus showing the tendency of the vessels to degeneration and rupture.

Mr. WOODHOUSE BRAINE had seen a good instance of purpura following the use of chloral. A gentleman at sixty had been given chloral to induce sleep, in doses of 1 dr. the first night, 10 gr. the second, 2 sc. the third, and then  $\frac{1}{2}$  dr. for two successive nights. On the sixth day large purpuric spots appeared on the calves. On two other occasions he took the same doses of chloral, with the same effects.

Dr. THEODORE WILLIAMS highly praised Dr. Richardson's classification, being based as it was on the analysis of the blood, and would prove very useful to future workers, though modification might become necessary, especially to the connection of purpura with diseases of various organs. He was surprised at no mention being made of the common occurrence of purpura with diseases of the liver, especially in jaundice, where purpura, chiefly of the lower extremities, often made its appearance when the jaundice had lasted long; it was by no means rare in the later stages of granular kidney. Its occurrence in malarious districts was well known, and of its following the use of chloral. Dr. Williams gave a marked example of an asthmatic who took chloral for three days at the rate of a scruple every three hours; the asthma ceased, but a purpuric eruption appeared affecting the lower extremities and abdomen, and lasted two days. Its disappearance was followed by a return of the asthma.

Dr. HARE remarked on the fatal prognosis which purpura in scarlet fever generally indicated. He had never known a case of scarlet fever where even one purpuric spot appeared that had not proved fatal.

Dr. SANSON dwelt on the great difficulty of diagnosing purpura from some forms of variola, and in reply

Dr. Richardson stated that in his classification he had kept quite clear of variola and scarlatina, which, with cases arising from marsh miasm, he regarded as the result of severe blood-poisoning, forming a class by themselves; syphilitic purpura and that arising from poisoning by chloral or mercury he would include in class 2, or saline purpura; and he remarked that both fibrine and albumen had been diffused with saline and then dialysed through animal membranes. He was sorry to say that as yet he knew little about the pulse in purpura, and hoped for future observation on this point.

NOVEMBER 16TH, 1874.

Mr. BRAINE showed (through the kindness of Dr. Waller Lewis) one of the *employees* at the General Post Office, who had a large hypertrophied fold of the mucous membrane on each side of the frænum coming from the upper lip, and so large that when the lip was drawn tightly over the teeth the growth slipped from behind it, and, dropping down, entirely covered the upper teeth. The patient was about 18 years of age. He stated that the growth commenced about six years ago. There was no family history of any like growth.

Mr. NAPIER had noticed this peculiarity when there had been great irritation of the mucous membrane of the mouth. Certain teeth being absent, the edges of the other teeth irritated the soft parts, and this was the result.

Dr. FAYRER had seen something similar in another part of the body, in the scrotum, and he had called it evoid elephantiasis. It had since been described by Dr. Vandyke Carter under another name, and shown to be an affection of the lymphatics of the parts.

Mr. SEWILL had seen the affection before, generally in scrofulous patients.

Mr. BRAINE also exhibited for Dr. Cleveland a small tumour of doubtful character removed from a lady, æt. 74. She had always enjoyed general good health, and from her earliest recollection had had a small swelling or wart on the skin of the abdomen. About nine years ago this growth had bled a little, but did not begin to enlarge until the beginning of the present year, when, after a journey from Scotland, it grew to the size of a hazel nut, causing considerable pain and uneasiness. In the course of three or four days it presented a melanotic appearance; and when shown to Sir James Paget, he believed it to be cancerous.

It was removed by the knife. A digging incision was made, and the wound freely dressed with cold perchloride of iron. The patient has since done well.

The PRESIDENT had noticed in the case of warts about the vagina and anus, that after successive removals the last growths are certainly of a malignant kind.

Mr. SEBASTIAN WILKINSON said it should be noted that the locality from which this growth was removed was often the seat of epithelioma, and that many of these so-called warts were really epithelial growths.

Dr. ROUTH remarked that, as regards vaginal warts and epithelioma, the microscope gave no distinctions, for under it they were identical.

Mr. W. D. NAPIER then made a communication,

SOMETHING NEW, OR BELIEVED TO BE SO, IN THE SCIENCE OF DENTAL SURGERY.

After a brief allusion to the encouragement afforded by the Society towards the general advancement of science, he proceeded to treat of a case lately under his care, in which he had, by an original mode of treatment, been able to perfect a new and, as he esteemed it, desirable process of operating on the mouth without causing pain to the patient, who, in this instance, objected to the use of anæsthesia in any shape. The case, which was illustrated by casts, was somewhat rare, the teeth in both jaws having been reduced by mercurial salivation or other cause to the condition of sharp, jagged spikes, giving great discomfort and nervous irritation. The process of filing necessary to reduce them to the level of the gum was done satisfactorily by the aid of ether locally applied during the operation, until the exposure of the nerve, &c., rendered the employment of it nugatory. It was then—in lieu of destroying the nerve, which is the ordinary practice under these circumstances—Mr. Napier very cautiously and gently applied to the exposed portion of it in each tooth successively a pencil of hickory wood dipped in nitric acid, by which simple method it was rendered insensate, and the operation necessary to enable the mouth to receive artificial substitutes was completed. Mr. Napier was anxious that the principle involved should receive a fair share of attention, as he held the present system of nerve-demolition to be at variance with true science. The paper concluded with an expression of the author's hope that the merits of a better acquaintance with dental surgery would soon be recognised by others than those whose speciality it is, and he intimated his conviction that the latter would be inestimably benefited by obtaining their education and training in duly organised schools, where alone they can obtain perfected instruction in every branch of physiology that will enable them to excel in one.

Mr. SEWILL asked whether the pulps were exposed when the patient was first seen, and whether they were removed under an anæsthetic. If there was no exposure, Mr. Sewill recommended the use of astringents, and if there was, he much preferred total removal of the pulp to the very painful application of actual cautery.

Dr. CRISP asked whether nitric acid caused pain, and whether there was a history of syphilis.

Dr. LEE, who had seen the patient, testified to his general improvement in health since his teeth had been set right.

Mr. NAPIER, in reply, gave a short explanation on the points in question.

Dr. R. J. LEE then read a paper on

#### MATERNAL IMPRESSIONS.

The author commenced by expressing an opinion that although the subject had been often discussed, yet the progress of scientific knowledge was a reason for considering it from time to time if it could be proved that there were sufficient grounds for modifying our views regarding it. The case related by Moriceau of his relation, who was affected during life with tremor of the hands in consequence of the fright his mother sustained previous to his birth from the sudden loss of her husband (who was stabbed by a servant), was taken as an example of a certain class of cases of this kind. The value of a system of classification of abnormalities in the fetus according to anatomical details was shown to be useful in establishing the view that such abnormalities follow certain physiological laws, but that this system does not attempt to explain their cause. The necessity of defining what we mean by maternal impression was pointed out as the first step towards explaining the manner in which

an impression can affect the child. There appeared to be certain effects which followed purely emotional disturbances, and others which were the consequences of impressions produced by objects of fear or disgust, while between purely emotional and objective impressions there were a great variety which affected the emotions and the senses simultaneously. Experience proved that the first and last of these classes of impressions were more commonly stated to be causes of various abnormal conditions in the child, but that such effects were exhibited in some deficiency of its intellectual and moral nature rather than in deformity or abnormality in special organs or parts of its body. In illustration of the truth of this view a few cases were selected; and Dr. Lee concluded by recommending it to the attention of the members of the Society as of greater importance than that which attempts to connect particular kinds of deformity with the object which was stated to have produced "an impression" on the mother.

#### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

NOVEMBER 10.

MR. WHITE COOPER in the Chair.

A paper was read by Mr. WEST entitled,

OBSERVATIONS ON THE ELIMINATION OF UREA IN CERTAIN DISEASES.

The author related cases of pneumonia, rheumatic fever, Addison's disease, diabetes, and aneurism.

It was found in pneumonia cases that when the temperature was 104°2, there were excreted 14·87 grammes of urea, and when the temperature was 100°3, the quantity of urea excreted was 20·00. In another case, where the patient died, the percentage of urea varied between 2·2 and 2·35. There was much nitrogen taken in by the patients, and the percentage eliminated was very small. It seems probable that, in pneumonia, there is excretion of the nitrogen by the kidneys taking place in some other form than that of urea. The excretion of urea seems to vary greatly in pneumonia.

In the cases of Addison's disease, the amount of urea eliminated is diminished, and this on account of the want of appetite.

In the diabetes case, the great amount of urea excreted was remarkable, as much as 57·5 grammes a day. It was not on account of the food the patient took, but on the waste of tissues. The percentage of urea is always high in fevers, and falls when the pyrexia ceases. Changes of diet in fever cause the same oscillations as in health. It would be important to ascertain the total nitrogen excreted.

Dr. DICKINSON said that Haughton observed that the amount of urea in diabetes was more or less connected with the sugar. Three grammes per 14 lbs. is about the amount of urea excreted per diem in health: making this allowance, all the nitrogen going into the urea and the carbon and hydrogen into the sugar. In the cases of diabetes insipidus, the urea is largely increased. The author observed that in one case of polyurea he had examined the amount, and not found this.

#### THE ACTION OF DRUGS.

##### IV.

THE fifth section of Professor Bennett's report is devoted to recording the results of various experiments undertaken to ascertain the antagonism between sulphate of atropia and meconate of morphia. The inquiry was divided into three parts: 1. To ascertain as precisely as

possible the physiological action of meconate of morphia on the rabbit and on the dog; 2. To ascertain in the same way the physiological action of sulphate of atropia on the rabbit and on the dog; and 3. To ascertain the combined action of the two substances, introduced either simultaneously, or the one before the other, in these animals.

In reference to the first point, Experiment 299 shows that a rabbit weighing  $3\frac{1}{2}$  lbs. recovered after receiving six grains of the morphia salt; while in Experiment 300 one of the same weight died after receiving nine grains. Yet in former report ten grains were given as the minimum fatal dose. In both cases lowering of respiration and cardiac impulse was observed.

Experiments 301, 302, 303 are extremely useful in showing that in rabbits under the influence of morphia the sciatic nerve responds to stimulus; also that if the vagi be exposed and stimulated by the induction current, total stoppage of the heart's action follows; also, if the sympathetic nerve be stimulated, contraction of pupil follows. These experiments are exceedingly interesting and important.

Experiments 304, 305 we quote at full length, as, being on dogs, they are of more interest and more to be relied upon as a means of elucidating the physiological action of the drug in question. They also serve to indicate the difference in the dose required to affect a rabbit and a dog, for in Experiment 304, on a dog, we find marked physiological effects produced by 2 grains, and in Experiment 305 by  $3\frac{1}{2}$  grains, while in rabbits 6, 9, and 10 grains were given; and it has already been shown that these animals will bear from 7 to 8 grains without any marked effect except drowsiness and contraction of pupil and slight spasms (Experiment 284). This difference should be borne in mind by future experimenters.

"*Experiment 304.*—Male black and tan terrier dog, weighing 20 $\frac{1}{2}$  lbs. Ten minims of a solution of meconate of morphia, containing two grains of the meconate, were injected under the skin on the back. In four minutes it vomited three times. In another minute it attempted to stand up, and trembled violently. It laid its head down on the floor. In another minute it lay flat on its abdomen, with its head extended on the fore paws, and the tongue protruded. The pupil was now much contracted. It remained in this condition for half-an-hour. It defæcated a quantity of soft green pulaceous matter. In another half hour it walked with a staggering gait to the other end of the laboratory, when it lay down and apparently fell asleep. It was roused three hours after the time of receiving the dose of meconate of morphia, and it then took food. It recovered slowly, as for several days it was observed that the hind legs were weak. There seemed to be also, to a slight extent, a loss of co-ordinating power.

"*Experiment 305.*—Male Scotch terrier, weighing 14 $\frac{1}{2}$  lbs. Three grains and a half of meconate of morphia dissolved in eighteen minims of distilled water were injected under the skin of the back. The phenomena seen in this case were similar to those just described in experiment 304. Thirty-five minutes after having received the dose, the animal was deeply narcotised. The pupils were contracted to a mere point. It could not be aroused in any way. The respirations were slow. The cardiac pulsations were so feeble that they could scarcely be perceived through the walls of the chest. While the animal was in this state, the three following experiments were made as quickly as possible. 1. The sciatic nerve was exposed and stimulated by a weak induction current. It

responded to an extremely feeble current. The muscles of the leg also contracted when stimulated directly. 2. The pneumogastric nerve on the right side was exposed in the neck, and stimulated by a weak induction current. Stimulation was found to arrest the action of the heart. 3. The sympathetic nerve on the right side was exposed and also stimulated by a weak induction current. The heart was then noticed to pulsate more quickly. On cutting the sympathetic and stimulating the cephalic end, the pupil slowly dilated but not to its full size. The animal was then killed. During the operation there appeared to be complete anæsthesia. On opening the thorax and stimulating the phrenic nerves, the diaphragm contracted powerfully.

"From these experiments the following conclusions regarding the physiological action of meconate of morphia on rabbits and dogs may be drawn.

"1. In both animals, meconate of morphia acts on the encephalon and on the spinal cord, but in the case of dogs the action is more cerebral, while in rabbits it is more spinal.

"2. As John Harley states, (a) either delirium or hypnotic effects may be produced. In the experiments recorded, hypnotism was the predominant effect.

"3. In the case of rabbits, death is often produced by convulsions.

"4. In both cases, while deeply under the influence of the drug, as stimulation of the motor nerves caused muscular contractions, we must hold that the sensibility and conducting power of the nerves are not destroyed.

"5. In both cases, stimulation of the vagus in the neck causes stoppage of the action of the heart. Consequently, the vaso-inhibitory fibres in the vagus are not paralysed by meconate of morphia. It is possible, as Harley appears to think, (b) that these fibres may be irritated.

"6. Stimulation of the sympathetic in both cases causes dilatation of the pupil. Consequently the sympathetic trunk is not paralysed, and the contraction of the pupil must be owing to the cranial origins of the third nerve being irritated, thus causing contraction of the circular fibres of the iris, governed by that nerve, and consequent contraction of the pupil. (c)

"7. Morphia may affect the action of certain nerves by paralysing the nerve centres from which they issue, but the nerves themselves apparently still retain sensibility and conductivity."

The conclusions arrived at, which we have quoted above, are of great value, and we must say these experiments are the most satisfactory, as placing on a pretty firm basis our knowledge of the physiological action of this very useful drug.

Next we have the record of experiments conducted to ascertain the physiological action of sulphate of atropia on rabbits and dogs, and in reference to rabbits Professor Bennett says:—

"In small doses of from two to four grains the only observable symptoms are dilatation of the pupils, quickening of the cardiac contractions, and of the number of respiratory movements. When four to eight grains are given, in addition to these symptoms, there are slight paralysis, more especially of the hind extremities, and a greater increase in the number of cardiac impulses. Above

(a) Harley, "Old Vegetable Neurotics."

(b) See Harley, "Action on the Pupils," pp. 136-137

(c) Harley lays great stress on the action of morphia on the vagus, but his facts do not appear to warrant his conclusions. He says (p. 184): "Derangement of the vagus nerve is the main source of the distress which follows; its sentient branches are blunted, and the lungs no longer invite a flow of blood; its motor branches convey only cramp to the muscular parts; the mechanical suction-power of the chest is depressed, and the lungs themselves tend to collapse. The right heart soon becomes distended; cardiac distress is complained of; the pulse loses force and volume, intermits, and syncope results."

this dose the action of the heart and lungs becomes embarrassed—the heart's action being much weakened, and there is also a reduction in the rate of respirations. After doses above sixteen grains, death ensues with paralysis, tremors, spasms, and perhaps convulsions."

Yet, on page 465 (already referred to), it is stated that up to four or four and a-half grains no symptoms are observed, and with four to six grains dilatation of pupil, uneasiness, restlessness, reduction of respiration, and acceleration of cardiac impulses, and twenty grains were given as a minimum fatal dose. It is to be regretted that the minimum physiological dose was not more accurately determined. However, in reference to the above record of the different actions of small and large doses of atropia—viz., a stimulant action when small, a depressant when large—we here draw attention to Dr. John Harley's (page 217) remarks. He says that in moderate doses this drug may be regarded as a direct and powerful stimulant of the sympathetic nervous system, and that in man 1-48th of a grain is sufficient to produce the stimulant effects; but if large doses are given the force and activity of the heart is diminished. This dual action of a drug, which we see applies to all animals, should be borne in mind both when using a drug in the treatment of disease or as an antagonist to another drug.

The next series of experiments (306, 313) were made on dogs to ascertain the minimum fatal dose, which is stated to be three-fourths of a grain. We here quote experiments 306, 311, and 312, as bearing out what we have said about the dual action of drugs:

"*Experiment 306.*—A Scotch terrier, weighing 16 lbs., received the one-eightieth of a grain of sulphate of atropia in ten minims of water under the skin of the back. Before the substance was introduced, the transverse diameter of the pupil was 10-50ths of an inch. Pulse 118, respirations 18 per minute. In four minutes the pulse had risen to 280, and was very firm to the touch. The pupils were dilated to their full extent five minutes after the dose. The lips, inner surface of the cheeks, surface of the tongue, and the lining membrane of the nose were all dry. In three-quarters of an hour the pulse fell to 250. The animal appeared to be excited. It ran backwards and forwards, came against the legs of the laboratory table, and sometimes sat down and whined. At the end of four hours after receiving the dose, no effects could be observed.

"*Experiment 311.*—Ten days afterwards the same dog was 13½ lbs. in weight, but it appeared to be out of condition so far as its skin was concerned. The hair was scanty, more especially near the mouth. In this experiment, half a grain of sulphate of atropia was injected under the skin near the nape of the neck. The effects were the same, although much intensified. The animal lay prostrate, with the head resting on the fore paws, the mouth partially open, and the tongue lolling out. It was insensible. It could not be roused by pushing. There were a few convulsive jerks of the muscles of the back and neck which tended to cause the head to move suddenly backwards. It remained in this condition for nine hours, when it slowly recovered. No further experiments were made on this animal, as it remained out of condition for a long time. It completely recovered.

"*Experiment 312.*—The fatal dose of sulphate of atropia for a dog being now evidently approached, it was determined to ascertain it, if possible, with more precision. An experiment was accordingly made on a mongrel English terrier, weighing 15 lbs. Three-fourths of a grain of sulphate of atropia in thirty minims of water were injected under the skin over the left flank. The phenomena observed after this large dose were the same

as those just described. One hour after the administration of the dose, the animal was prostrate, with pupils widely dilated. The cardiac pulsations were too rapid to be counted, and they were also so feeble as scarcely to be felt. The respirations were irregular and shallow. There were convulsive twitchings of the muscles, more especially those of the back and neck. The sphincters were paralysed, and the faeces and urine came away frequently. Three hours after the dose, a smart convulsion occurred, the body was bent backwards, the mouth opened widely, the heart suddenly ceased, and the animal was dead."

We also refer those of our readers interested in this subject to Dr. Harley's and Messrs. Burness and Mavor's works, where several experiments on dogs, horses, and men with this drug are recorded.

Experiment 314 indicated that when a dog is under the influence of atropia the motor nerve-tubes are not paralysed; but stimulation of the vagi produced no appreciable effect on the number of the cardiac pulsations, and this indicates, as Professor Bennett says, that atropia paralyzes either the trunk of the cardiac branches of the vagi, or the intrinsic nerve centres in the heart, with which the cardiac branches are connected. Such being the case, we can understand how a *large* dose of atropia will intensify and prolong the action of morphia, and yet by its stimulant action in *small* doses on the heart it may, in conjunction with other remedies, aid in recovery in cases of morphia poisoning, although it cannot be regarded as a *direct antidote*. This fact has been commented on by various observers recently.

Report 5 is devoted to a consideration of the antagonism between sulphate of atropia and meconate of morphia, and the inquiry was divided into two parts—viz., how far does sulphate of atropia influence the effects of meconate of morphia when given, first, after, and secondly, before that drug.

To ascertain the first point, twenty-one experiments were made on rabbits, the sulphate of atropia being administered at various intervals after a fatal dose of meconate of morphia. Then, to ascertain the second point, eleven experiments were made, in which one and three-quarters or two grains of sulphate of atropia were given before the meconate of morphia.

In reference to these experiments Professor Bennett remarks—

"That, out of twenty-one experiments in which what was held to be a fatal dose of meconate of morphia was followed by a dose of sulphate of atropia, six recovered. When the crucial test was applied to these six rabbits six days later, by injecting ten grains of meconate of morphia without sulphate of atropia, four died, and two recovered. In the case of the latter, the dose of ten grains cannot be considered a fatal dose. In all cases, there could be no doubt that the subsequent injection postponed the fatal issue, if it did not save life. As the sulphate of atropia resembles meconate of morphia in producing convulsions when given in large doses, larger doses of the former than one grain and three-quarters were not given in this set of experiments; but it appeared, from watching the experiments, that the sulphate of atropia favoured the chance of recovery after a fatal dose of meconate of morphia, by causing contraction of the blood-vessels. After sulphate of atropia, the pupil (which was contracted by a dose of meconate of morphia previously given) slowly dilated; and in those cases in which doses of sulphate of atropia, amounting to one and a half or one and three-quarters of

a grain, were given within six minutes after the meconate of morphia, the pupil remained nearly of its normal size before the experiment. It was observed also that the vessels of the ear, turgid with blood after the large dose of meconate of morphia, contracted considerably about eight or ten minutes after the introduction of the sulphate of atropia."

Also "that, out of eleven instances in which a dose of sulphate of atropia had been given previous to what was held to be a fatal dose of meconate of morphia, seven recovered—a larger proportion than when the meconate of morphia was given first. Of these seven cases, four died by the crucial experiment of giving meconate of morphia with sulphate of atropia, while three recovered. These numbers are so close that, even although it were admitted that sulphate of atropia modified the symptoms produced by meconate of morphia, and postponed death, it might be objected that, in those cases of recovery, ten grains of meconate of morphia was not a certainly fatal dose. Eighteen rabbits were therefore collected, of as nearly the same weight as possible; and two sets of experiments were made, in which larger doses of meconate of morphia were employed. In nine cases, the meconate of morphia was given first, and in the remaining nine it was given last."

And then passes on to tabulate the results in these eighteen cases. This is followed by a record of ten experiments with meconate of morphia given after large doses of sulphate of atropia, and the report thus concludes:

"It does not appear from this table that meconate of morphia favours recovery after a large dose of sulphate of atropia. In several cases—Nos. 372 and 373—the time of death seemed to be rather hastened than delayed, and the animals died in severe convulsions, preceded by tremors and pushing backwards of the body. In all of these cases, it was observed that large doses of sulphate of atropia produced great acceleration of the action of the heart, notwithstanding the administration of meconate of morphia. (The italics are ours.) This appeared to indicate either complete or partial paralysis of the vaso-inhibitory branches of the vagus or stimulation of the sympathetic. It was important, however, to ascertain more precisely whether or not the meconate of morphia relieved in any way, or to any extent, this paralysis of the vaso-inhibitory nerves.

"Experiment 375.—An experiment was accordingly made on a large rabbit, weighing 4½ lbs. It first of all received seven grains of sulphate of atropia under the skin of the back. The pulse soon became accelerated. It was then fixed in Czermak's rabbit holder, and the pneumogastric nerves on both sides quickly exposed. By proper electrical arrangements, one or both nerves were stimulated, and the cardiac pulsations counted before, during, and after the application of the stimulus. It was found that there was no perceptible retardation of the heart's action on stimulating the vagi, indicating paralysis of the vaso-inhibitory nerves. Eight grains of meconate of morphia were now introduced by injection into the jugular vein, and the animal was left undisturbed for four minutes. The stimulus was again applied to the pneumogastrics, with the same negative effect of producing no diminution in the number of the cardiac pulsations. The stimulus was repeatedly applied with the same effect. It was therefore proved by this experiment that, while sulphate of atropia did paralyse the vaso-inhibitory nerve-tubes in the vagus, or the intrinsic motor ganglia in the heart in connection with these nerves, the subsequent exhibition of meconate of morphia did not remove this effect; and that, in this respect, the two active substances were not physiologically antagonistic.

"The inferences to be drawn from the experiments on rabbits are the following.

"1. Sulphate of atropia is physiologically antagonistic to meconate of morphia within a limited area;

"2. Meconate of morphia does not act beneficially after a large dose of sulphate of atropia, for in these cases the tendency to death is greater than if a large dose of either substance had been given alone;

"3. Meconate of morphia is not specifically antagonistic to the action of sulphate of atropia on the vaso-inhibitory nerves of the heart; and

"4. The beneficial action of sulphate of atropia after the administration of large doses of meconate of morphia is probably due to the action sulphate of atropia exercises on the blood-vessels. It causes contraction of these, and thus reduces the risk of death from cerebral or spinal congestion, as is known to occur after the introduction of fatal doses of meconate of morphia. It may also assist up to a certain point, not precisely fixed in these experiments, by stimulating the action of the heart through the sympathetic, and obviating the tendency to death from deficient respiration observed after large doses of morphia."

It is unnecessary to comment on these conclusions having done so in the course of our review of the various experiments. We must, however, express our gratitude to the experimenters for the immense labour they have devoted to this important point, and for the clear manner in which they have recorded the results.

## HOSPITAL SATURDAY.

THE Hospital Saturday accounts have at last been closed, and the liberality of the wealthy artisans of London in the cause of humanity is represented by a beggarly contribution of £5,800. To extract even this miserable sum from the superfluities of the working man it has cost, in processions, banners, and suchlike adventitious inducements no less a sum than £1,100, and the realized profit from the Hospital Saturday movement is represented by a grant of perhaps £50 a piece to the London medical charities, and the gratuitous advertising of a clique of meddlesome people, who are anxious to be considered philanthropists, and are not unwilling to have the public money passing through their fingers. Compared with this disgusting exhibition of selfishness on the part of the petted working man the efforts of the church-going upper classes stand out in honourable contrast, for the first Hospital Sunday produced no less a sum than £27,000, and the collection of that large bounty cost less than £750. We aver without hesitation that the London working men in their millions were in a better position to contribute such a sum than the upper and middle classes in their thousands; yet they have on this occasion conclusively demonstrated their utter meanness of mind and complete lack of humanity. As long as the working man can secure medical care for his own body and alleviation for his own pains by practising any amount of deception or whining he cares little for the sickness, misery, or starvation of those around him, even of his own class—nay, even of his own wife and children. He will spend a comfortable weekly income on skittles, drunkenness, or ruffianly laziness, but he won't spare even a sixpence a year to keep himself and his family above the pauper herd or to alleviate the miseries of his destitute fellow-worker. He will brawl republicanism and talk patriotism as long as he can get a platform upon which to display his ignorance and his abominable political creed but when the touchstone of charity is applied to him the

emptiness of his professions and the meanness of his character are at once made manifest. We take credit to ourselves for having, at the moment when Captain Mercier and his fellow-philanthropists started the Hospital Saturday scheme, repudiated its principle and prophesied its failure. If the result has taught the people who lavish their money and their sentiment upon the working man that the recipient of their charity is as a rule entirely unworthy of it, the Hospital Saturday movement will have yielded a more valuable result than is to be found in the glorification of a half-dozen of fussy people who mistake their well-intentioned but misplaced emotion for real philanthropy.

### CHARITY VOTING REFORM.

FROM the manifesto just issued by the Committee of the Charity Voting Reform Association we gather that an unusual amount of success has already attended the movement, while it affords unmistakable proof of the wide-spread discontent that prevails among the supporters of our charitable institutions with the abuses of the present mode of election of Beneficiaries. The Association numbers, in the short space of twelve months, upwards of two thousand members, subscribers of charities, all of whom are pledged to do their best to put an end to the mischievous operation of "charity electioneering," and it behoves managing committees and wire-pullers generally, who seem blind to the rottenness of the system, under which it appears to them that charity flourishes "like a green bay tree," to look about them in time, lest they should discover that an obstinate resistance has alienated the best part of their friends and subscribers.

It appears from the document alluded to that the operations of the Charity Voting Reform Association have already extended over a wide area; that upwards of 50,000 pamphlets, stating the objects and views of the Society, have been distributed among the subscribers to nineteen of the principal voting charities. It is apparent, therefore, that the time has now arrived for the subscribers themselves to take action in furtherance of the necessary reforms.

The recommendations made by the Committee to those subscribers who desire a reform of the system, but are still willing, for the present, to continue their subscriptions, are as follows:—

"1. That they endeavour to form a committee amongst themselves in each charity to bring the question of reform before their fellow-subscribers, and to urge a selection and classification of cases either by the present managers, or by a special committee, and that they call meetings in each charity for the purpose.

"2. That, in the meantime, they entrust their votes to the managing committees of the respective institutions, under the specific responsibility of investigating and classifying the cases of the candidates before they make use of such votes. Numerous subscribers have already adopted this plan; but it is desired to give to these scattered efforts the force of a combined movement, in the hope that managing committees will of themselves propose measures of reform.

"3. In the event of any managing committee declining to accept such responsibility, and giving no means to the subscribers to bestow their votes properly according to a classified list, it is hoped that subscribers will make their

opinions unmistakably known to the managing committee, in order that a full reform may be obtained, and that, failing this, they will select for their charitable donations institutions which are not open to the same serious evils."

Various papers containing full information on the subject may be obtained from the Secretary of the Charity Voting Reform Association, at No. 30 Charing Cross, to whom subscriptions may be paid in furtherance of the objects of the Association.

## Notes on Current Topics.

### Blood-drinkers.

THE *Laboratory* says that, upon inquiry at slaughter-houses, it is found that there are nearly two hundred persons in the city of New York who are in the habit of drinking blood flowing warmly from oxen, for strengthening purposes and for the cure of certain diseases. A lady is reported to have spoken to an inquirer as follows: "Professor Velpeau, of Paris, prescribed blood for me. I was consumptive, and hastening to the grave. It has prolonged my life fifteen years. I had the utmost repugnance for it at first, but now a half-pint of hot blood from a well-conditioned ox is the greatest luxury of my life. My sister's baby so far has been preserved and nourished with little else but blood. I know twenty persons who drink it in my own neighbourhood, to whom I have recommended it. It has extraordinary effects on some people, especially women, but should not be resorted to unless there is absolute weakness of the system." On a visit of the inquirer to a slaughter-house in Tenth Avenue, near Forty-second Street, he found a delicate-looking woman with a sickly boy holding a glass to the blood which ran from an ox with his throat cut. Both drank two or three glasses in turn, and departed with an appearance of added vigour. The proprietor said, "All last winter we had men, women, and children every morning to drink blood. They always imbibe beast's blood; never the blood of sheep. Some of them wince a bit at first, but, when you close your eyes, blood warm from the beast's neck has just the same taste as warm milk from the cow. We don't charge for the blood, excepting when we sell it to sugar-refiners."

### Puerperal Mortality.

AMONG the Chinese puerperal mortality is held, according to Dr. Jamieson, to rise as high as from one in twelve to one in twenty, an alarming and scarcely credible statement; yet Dr. Thin, lately of Shanghai, believes it to be true. The *Philadelphia Med. and Surg. Reporter* gives some statistics of the city of New York, recently published by Fordyce Barker, which shows a puerperal mortality of one in thirty-five, a terrible result; and on the surely extravagant admission that a quarter or even half of the births were not registered, we have here a very high figure. Faye states the puerperal mortality of Prussia as one in eighty-four; and that of Finland, according to Pippingskjöld, as one in one hundred; and that of Norway, as one in one hundred and thirty-one. Dr. Duncan

found that in Edinburgh and Glasgow, in 1855, the mortality of married women within six weeks after delivery was one in one hundred and seven, at least. From a large collection of data, he estimated the mortality within four weeks after delivery as about one in one hundred and twenty.

#### Legality of Patents to Quack Medicines.

DR. DYRENFURTH, the newly-appointed principal examiner in the class of chemistry, in the Patent Office of the United States, says the *New York Nation*, has recently rejected an application for letters patent for a "medical compound," substantially upon the grounds that a mere mechanical mixture, or assemblage without chemical union, of a number of medical ingredients, possessing well-known properties, is neither such invention nor discovery of a new and useful composition of matter as is contemplated by the law, its preparation involving at most only the exercise of a skill common, in varying degree, to all persons having a knowledge of disease and of the curative properties of drugs and medicines; that, if patents may issue upon this and kindred applications, it follows, such skill being exercised whenever a physician writes an original prescription, that thousands of patentable inventions of this class are made daily, a fatal *reductio ad absurdum*, and that the creation of monopolies restraining others from the exercise of such skill is in contravention of public policy and human welfare.

#### The Sham Diploma Trade.

A LETTER was lately received by the Mayor of Philadelphia, from the United States Consul at Malaga, giving information of the sale of diplomas issued by the American University, in Spain, by the advertisements of Dr. Van Der Vyver, of Jersey, England. An answer was sent, stating that the matter was now in the hands of the Attorney-General, who has applied for a writ of quo warranto against the American University.

#### Tuberculosis not Inoculable.

IN a late communication to the Academy of Sciences of Paris, M. Metzquer tried to upset Villemin's doctrine. For the last five years the author has made experiments (from seventy to eighty), under the direction of Prof. Feltz, of the Faculty of Nancy. He never succeeded in inducing pulmonary consumption in the inoculated animals. The results were capillary embolism, infarctus, vesicular pneumonia, &c., all of which lesions have (the author maintains) been confounded with tubercle. Tuberculosis may, however, be generated in animals (says M. Metzquer) without inoculation of tubercular matter, by rough treatment, bad food, and, strange to say, by inflicting a wound upon them.

#### Congenital Absence of the Corpus Callosum.

DR. MALINVERNI, Professor of Pathological Anatomy at Turin, gives the detailed description of the brain of a man, forty years of age, who died of a gastro-enteric affection. During life he had never exhibited any deficiency or perversion of intellect, and yet after death the corpus callosum and septum lucidum were found to be entirely absent.

#### Cremation as a Cause of Indian Cholera.

THE *Abeille Medical*, in a recent article in opposition to cremation, makes the following remarkable statements:—

Hindoostan, or the peninsular of India, is situated in the tropic zone. The population amounts to nearly 180 millions of people, who all—with the exception of a few millions of Mussulmen—profess the religion of Brahma. The Hindoos are compelled by the worship of Brahma to burn the corpses of their dead, and even the women deem it an honour to sacrifice themselves to the flames on the funeral piles of their deceased husbands. During the thousands of years during which this religious rite has been solemnised how many millions of corpses may there have been burned to ashes! what masses of deleterious gases have there impregnated the atmosphere! what chemical formations and decompositions have there happened by fire!

In our opinion these cremations are the real cause of Asiatic cholera (cholera asphyxia). It is our firm conviction that the poisonous gases generated in the most populous districts for thousands of years is the *only* cause of this terrible disease. This miasm generated beneath the tropic sky, hovers in the air during the day, sinks at night into the lower portions, mixes with the water and various kinds of food, and permeates the lungs in the process of respiration. This poisonous gas spreading in the living organism causes diarrhoea, vomiting, convulsions, and cynosis, the general symptoms of this plague, but which appear suddenly and with greater vehemence as sure symptoms of cholera.

#### The Proposed Hospital for Contagious Diseases at Hampstead.

IN our last we recorded the opposition to the proposed reconversion of the temporary Small-pox Hospital at Hampstead into a permanent hospital for contagious diseases generally by the Vestry. The Vestry has been greatly strengthened in its course by a meeting of the inhabitants, headed by the Board of Guardians, held on Thursday, at which it was unanimously resolved:—

"That this Board desires to co-operate with the Vestry of Hampstead in the attempt to obtain, by every legitimate means, the reversal of the present decision of the Asylums Board to erect on the present site a permanent hospital for contagious and infectious diseases."

Mr. Thomas Bridger, clerk to the Board, was instructed to forward a copy of this resolution to the Hampstead Vestry, which body has appointed a committee to take all necessary steps to obtain a change of site, and to co-operate with other persons willing to assist in this object. The site proposed is now occupied by temporary buildings, which have been used for relapsing fever and small-pox, and are now occupied as an asylum for imbeciles. These buildings, which closely abut on houses, it is now proposed by the Asylums Board to convert into a permanent hospital for contagious and epidemic diseases, at a cost of £80,000.

#### Tooting Cemetery.

MR. HOLLAND, the Government Inspector of Burial Grounds, has held an official inquiry into the serious allegations made respecting the management of Tooting

Cemetery and the way in which bodies were interred. It had been asserted in the first place, that the foot of earth which the authorities require shall be placed on the top of each coffin before another is laid in the same grave, had been dispensed with, or, at least, that it was frequently removed in order that the lower coffin might be seen by the relatives of the deceased person. Both these charges were admitted to be substantially well founded. The foot of earth which should separate the coffins had been reduced in order that one grave might contain a greater number of interments. This practice it had, moreover, been asserted had the authority of Mr. Holland, who expressed himself greatly astonished that he could have been supposed in any way to sanction the infringement of regulations which it was his special duty to see enforced. This assertion appeared to be founded on a misapprehension of what was meant by a "sufficient covering of earth." Mr. Holland, of course, understanding by that expression the stipulated foot, whereas in the opinion of the inspector of the cemetery the sufficient covering to which Mr. Holland had given his approval was four or five inches. In the case of private graves the coffins, it was admitted, were allowed to be laid without any intervening earth. The most serious part of the charge against the Tooting Cemetery Board, however, was that they had never yet adopted any measures for the sufficient drainage of the cemetery. A very insufficient system of mere surface drainage was, it had been stated, all that had ever been done in this way, and in one case, at least, a coffin had been deposited in a grave with water in it sufficient to cover the head of it. This also was admitted by the Burial Board, the chairman of which, Mr. Robert Taylor, explained that the more efficient drainage of the ground had been under consideration, and that communications had been in progress for the past eight years. Mr. Holland remarked that communication with the main drainage was what was required, and intimated that unless some steps were speedily taken in the matter the closing of the cemetery would probably be the result. In the course of the inquiry it transpired that the entire drainage of the cemetery was conducted into a neighbouring ditch, which discharged itself into the river Wendell, from which many of the inhabitants in its vicinity were accustomed to draw supplies. The surveyor to the board, Mr. Macintosh, had prepared plans for a more efficient system of drainage, but nothing beyond had been done, nor was it even decided which of the three propositions should be adopted, and it appeared from the evidence brought before Mr. Holland, that from the situation of the ground the most satisfactory system that was practicable would give only about eight feet of drainage, whereas from the depth of the graves usually dug here some fifteen feet would be requisite. At the close of the inquiry, a gentleman present asked Mr. Holland's opinion on the depth of ground requisite for obviating any unpleasant effluvia from a grave. Mr. Holland, having made experiments on the subject, thought three feet fully met all the requirements.

THE stamp duty on patent medicines in the year ended March 31 last amounted to £99,807, and yielded a net income of £95,388, while the year's duty on medicine vendors amounted to £7,378.

### The New Death Certificate.

As our readers are aware, the form of certificate of death has been for some time under consideration. At length it has been decided to issue a new form, more in accordance with the wishes of the profession, as expressed by us in several articles, as well as by our contemporaries. It is but natural we should object to certify to the age of our patients, and even to the time of their death, when we do not happen to be present, as is so rarely the case. The new books will, it is thought, be ready for the new year, and application for them must be made to the district registrars. They are only to be issued to practitioners whose names appear in the *Medical Register*.

Prior to finally settling the Form, it was submitted by the Registrar-General to the General Medical Council, to the Presidents of the Colleges of Physicians and Surgeons, and to the Master of the Society of Apothecaries, and all have approved of it.

The new Form runs thus :—

#### MEDICAL CERTIFICATE OF THE CAUSE OF DEATH.

[To be given by the medical attendant to the person whose duty it is to give information of the death to the registrar.]

I hereby certify that I attended.....  
whose age was stated to be.....; that I last saw  
h..... on the..... day of....., 18.....; that  
he died\*..... on the..... day of.....  
18....., at.....; and that to the best of  
my knowledge and belief the cause of h..... death was as  
hereunder written.

Cause of Death.	Duration of Disease.			
	Years.	Months.	Days.	Hours.
(a) Primary.....				
(b) Secondary.....				
(c).....				

Witness my hand, this..... day of....., 18.....  
Signature.....  
Registered Qualification.....  
Residence.....

\* Should the medical attendant not feel justified in taking upon himself the responsibility of certifying the fact of death, he may here insert the words "as I am informed."

At the foot of the Form is a caution against the use of it for any purpose whatever except that of delivering it to the registrar; and persons to whom the certificates are given by practitioners will incur a penalty of £2 if they neglect to deliver such certificates to the registrars.

### Scarlatina in Ireland.

THE Registrar-General's returns for the last week hold out no hope of a diminution in the mortality from the long-protracted epidemic of scarlatina which has prevailed in Ireland. The deaths in Dublin for the week which ended on the 14th were 18, or 4 more than in the previous week. In Belfast the disease is assuming very serious proportions, no less than 52 deaths being registered last week, or 16 more than in the preceding. In Thurles also the epidemic is said to be on the increase.

It is stated that the Local Government Board is engaged in preparing a Bill to deal with the question of the purification of rivers.

### Visitation of Examinations.

THE election of visitors by the Executive Committee of the Medical Council took place, as we said, on the 12th. The Committee selected two surgeons and two physicians from each division of the country, the candidates themselves having been nominated by the licensing bodies. For England, four out of the five visitors who acted last year—Messrs. Busk, Power, Barclay, and Bristow—were re-elected, Mr. Holmes not presenting himself again; for Ireland, Mr. William Stokes, Dr. Barton, Dr. Foot, and Dr. Purser were chosen; and for Scotland, Drs. Leishman, Douglas MacLagan, Struthers, and Patrick Heron Watson.

The obvious lessons to be learned from the selection are that the University interest is overwhelmingly predominant in the Executive Committee, and that experience in personal teaching is not considered by the Executive Committee to be a special qualification for a visitor of examinations. Almost every candidate who was chosen is known to have a special University learning, and this is the more to be regretted, because the Universities are the bodies upon whom judgment is to be pronounced this year. We shall see whether University men can find any flaw in University education.

### Analysts' Certificates.

THE episode of Dr. Saunders and the kiln-dried tea has brought in question the morality and the truthfulness of the analysts' certificates which it is customary to append to every announcement of a new alimentary speculation. It will be remembered that the *Times* had quoted a paragraph from Messrs. Sillar and Co.'s Tea Circular, stating that about 150 half-chests of redried tea, which had been under water in the Thames, had been publicly sold, and that the catalogues of sale declared that the "kiln-dried teas" had been analysed by Dr. Saunders, the Public Analyst for the City of London, and pronounced by him fit for sale in the market. One of the members of the Commission having called attention to the paragraph, and produced a sample of "tea-dust" which was alleged to have been taken from the parcel so certified by the public analyst, the matter was investigated by the Sanitary Committee, who, after conferring with Dr. Saunders and inspecting a sample of tea which he produced as a portion of that examined by him, reported that it was "serviceable and good," and had not the slightest resemblance to the sample produced before the Court.

The meaning of this is that the tea-brokers deceived Dr. Saunders into giving a recommendatory opinion by sending him a picked sample of the very best part of the tea, and then fraudulently used the certificate to cover a cargo of half-rotten and worthless rubbish which did not even remotely resemble in quality the tea which the analyst had examined. We have long suspected the existence of this roguish dodge, but the practice has not been publicly exposed until now. We have been accustomed to read the most gushing testimonials of wines and such like articles from men whom we know to be entirely incapable of stating anything which they did not know to be true, and to which our own gustatory acumen gave the lie direct. We believe it to be a common trick to send a specially excellent specimen of an article to a chemist, and then to use his certificate to cover the sale of an enormous

quantity of a product perfectly different, and vastly inferior in quality. Neither Dr. Saunders nor any other analyst is responsible for such a fraud, and the only way the roguish trader can be met is by making the public aware that analysts' certificates are only to be depended on when they are quoted by a firm which is known to be incapable of such a deception.

### Fever in London.

AT the meeting of the Metropolitan Asylums Board, on Saturday, it was shown that the general tendency of the recent epidemic of fever had been to increase in several districts since the last meeting of the Board. At the Homerton Fever Hospital there were 278 cases under treatment, which was a slight increase upon the last return. At the Stockwell Fever Hospital twenty-three fresh cases had been received from the Mitcham Schools, belonging to the Holborn Union, which was the largest number ever received from any single establishment. With this exception fever was about stationary at Stockwell.

### Irish Poor-law Guardianism.

THE Board of Guardians of the Gortin Union, in the co. Mayo, met on Wednesday last, the 18th, for the purpose of making appointments under the new Sanitary Act. The two medical officers of the union, Drs. Conan and Given, were appointed the sanitary officers of their respective districts, the relieving officer was appointed sub-sanitary officer, the clerk of the union was appointed executive officer, and for the office of consultant sanitary officer the workhouse medical officer was chosen. The proceedings throughout were of the most stormy and boisterous nature, although Mr. Hamilton, P. L. G., who was present, used all his endeavours, in his usual mild, courteous, and dignified manner, to "calm the troubled waters," with very little or no success. One enlightened member of the board most pertinaciously insisted that the guardians were not obliged to appoint a consultant sanitary officer at all; and on Mr. Hamilton endeavouring to explain to him that such appointment was made compulsory by the Local Government Board, he, Mr. Hamilton, was very plainly and very promptly informed that he was wrong, and the guardian persisted in his opinion, and refused to vote for any candidate for the consultancy. The allotment of the salaries gave rise to a vast amount of discussion. Some of the guardians were for giving no salaries at all, others would consider £2 10s. a most ample allowance for the doctors, whilst a few would actually have gone so far as to allow them £5. One "gentleman" very candidly remarked, when asked for what sum he would vote, that "he could have no fault whatever to find with the officers, that, in fact, he thought, more efficient officers could nowhere be found; but what," said he, "gentlemen, was I put here for? Why, simply to keep down the rates; and I must try to do so to please those who sent me here; so I now give my vote for the smallest sum." Other guardians who appeared disposed to be a little more liberal were met by the threat that "their constituents would be duly informed of their conduct," meaning that steps would be taken to prevent such

"liberal-minded" men being again elected to the "honourable" post of Poor-law guardian. After a most interminable amount of discussion, in which frequently nearly all the members present were talking at one and the same time, and in which, at another moment, a learned member might be seen holding his neighbour firmly in his place by the coat-tails to prevent him getting once more on his legs, the following scale of salaries for the different appointments was proposed and finally passed—viz.: For each of the dispensary doctors as sanitary officer, £3 per annum; for the sub-sanitary officer, £3 per annum; for the consultant sanitary officer, £3 per annum; and for the executive officer, £5 per annum. The acreage of the Gortin Union is 111,253, and the extent of district over which each sanitary officer will have control, amounts to 55,661, and 55,597 square acres respectively.

Comment is superfluous. The Gortin guardians may be a shade meaner and less educated than the average guardians of other unions; they are, however, by no means *sui generis*, but, on the contrary, are representative of a class which has a place on every board, and which constitutes, in many, the ruling majority. Any one acquainted with the Irish Poor-law system could have told Sir Michael Hicks Beach of their existence, and might thus have saved him from the fatal blunder of trusting his public health legislation to such hands; but we suppose it is the lot of legislators to be kept in the dark upon subjects with which all the world besides is familiar.

### Peculiar Physiological Action of Muscarine.

SCARCELY five years ago two investigators, Drs. Schmiedeberg and Kopp, of Dorpat, published the singular effects of a new alkaloid obtained from poisonous mushrooms, and especially from the *Agaricus muscarius*, whence the name of muscarine which they have given to this poison, and which has just been the subject of a recent communication by Dr. Prevost, of Geneva, to the Société de Biologie.

This young and learned physiologist has shown that when muscarine is injected into the veins of an animal, the heart is arrested in its diastole. The action of this poison is so much the more remarkable, since in such a case the heart is not dead, nor even paralysed, and its contractions can be aroused after several hours' silence.

### The Middlesex Coronership.

It is with great pleasure we announce that Dr. Hardwicke has been elected to succeed the late Dr. Lankester (whose efficient deputy he was for twelve years) in the office of Coroner for Central Middlesex. This is another triumph for the principle we have often urged, that medical men should always be selected for the office. A determined opposition was made by the legal interest; but Dr. Hardwicke obtained a majority of 246 over his lawyer opponent. There was danger when two medical men were in the field, but Dr. Diplock had the good sense to retire before it was too late. He is already coroner for one division, and we were therefore surprised at his coming forward when Dr. Hardwicke was in the field. However, "all's well that ends well," and

Dr. Hardwicke is so well-trying a coroner that it is superfluous to add that the office is in good keeping.

The second legal candidate also retired, leaving Dr. Hardwicke and Mr. Boulton, a member of the firm of Boulton and Sons, solicitors, alone to divide the electors. The polling booths were distributed over Islington, Marylebone, and Clerkenwell. Central Middlesex includes the parishes of St. Pancras, St. Marylebone, St. Mary, Islington, Paddington, Clerkenwell, St. Giles-in-the-Fields, and St. George's, Bloomsbury, St. Andrew, Holborn, and St. George the Martyr, St. John, Hampstead, Hornsey, Friern Barnet, South Mims, Finchley, St. Sepulchre, Saffron Hill Liberty, Liberty of the Rolls, Gray's Inn, Charterhouse, Lincoln's Inn, Staple Inn, Furnival's Inn, Hendon.

Dr. Hardwicke, when the figures were first announced, at ten o'clock, stood with a majority over Mr. Boulton of 24, and hour by hour that majority gradually crept up, until at four o'clock, out of 1,972 votes recorded, Dr. Hardwicke claimed 1,164.

### Coroners.

IN presence of the late election of coroner a number of facts have been collected by the *Globe* as to these officers. We have now 338 coroners in England and Wales, but only 185 of these act for counties or divisions of counties. Cities, towns, and boroughs have 114 coroners of their own, while 39 peculiar jurisdictions, coming under neither of these categories, are also to be met with. The number of inquests held in 1873 was 26,427—a figure decidedly above the average of recent years. Were all our coroners equally occupied, their labours would thus be comprised in the holding of some 78 inquests per annum. Of course, as a matter of fact, the distribution of the work varies enormously. Something like one inquest to every 500 of the population seems required in Middlesex, against one to every 1,000 in Yorkshire, and one to every 2,000 in Huntingdonshire. Curiously enough, however, Huntingdon boasts as many coroners as Middlesex, although the labours of the first five gentlemen do not appear to have reached an average of seven inquests in the year, while the latter five held on the average about 920 each. A Parliamentary return, issued two years ago, gives a good deal of curious information as to the varying areas of the coronerships of the county, the remunerations of the coroners, and the manner in which appointments are made. The peculiar jurisdictions, as they are called, exhibit some variety in this last respect, as the nomination to the post rests frequently with individuals. Thus, in the county of Huntingdon, to which we have alluded, all the five appointments go, as it is stated, "by privilege," the Earl of Sandwich, the Earl of Carysfort, Mr. Fellowes, M.P., enjoying the patronage in three cases, and the Duke of Manchester in the remaining two. The Lords of the Manor appoint in several instances. In Derbyshire we find one appointment made by grant from the Crown, while the right to another—the coronership for the hundred of High and Low Peak—follows the "Possession of the Horn of Ulphus." The Duchy of Lancaster appears in several instances to possess the right to appoint certain coroners, while the patronage falls in one case to the ecclesiastical

commissioners, and in another to the Dean and Chapter of Ely. Norfolk enjoys no less than seven different coroners, all paid out of the county rate, but only two of these are elected by the freeholders of the district; the other posts, some of which are not the least valuable, are in private hands. In Surrey there seems to be one very peculiar jurisdiction indeed, for though its limits are defined to be the portion of the Duchy of Lancaster in Surrey, the return we have quoted declares that the nature of the appointment, whether by charter, privilege, or election, is "not known," and this although the office seems to be at present filled and a salary of £67 3s. is attached to it. Much more uniform is the method of appointment to city or borough coronerships, where election by the Town Council appears the rule, broken, however, in the cases of Tenterden, Rye, and Haverfordwest, where trouble is saved by making the mayor for the time being *ex-officio* coroner.

THE Hospital Saturday collections in Wolverhampton, on the 17th inst., amounted to £1,284 3s. 9d. This sum, it is expected, will be considerably increased when the whole of the returns shall have been received.

THE London School Board is about to send circulars to all Board Schools in the metropolis requesting the managers to give immediate information to the local authority of any cases of infectious disease coming within their knowledge.

THE Marine Department of the Board of Trade have directed an official inquiry to be made into the circumstances attending the appearance of scurvy in a ship entering the Thames.

THE publication of the *Journal of Psychological Medicine*, which was edited by the late Dr. Forbes Winslow for sixteen years, is to be resumed by his son, Dr. Lyttleton S. Forbes Winslow. The journal is, however, to appear only twice annually.

THE medical officer of health for Marylebone reports that the mortality in the parish during the month of October was at the rate of 19.91 per 1000 annually. The deaths from diseases of the zymotic class amounted to 68. An unusual number of malignant cases of scarlet fever were registered, but the epidemic is now dying out.

THE number of births registered in London during the past week was 2,400, and deaths 1,517. The births were 65, and the deaths 81 below the average numbers in the corresponding week of the past ten years. The annual death rate, which in the three previous weeks had been 20, 21, 22, further rose last week to 23 per thousand of population.

THE next meeting of the Pharmaceutical Society of Great Britain will be held on December 2nd, at eight o'clock. The following papers will be read:—"An Additional Method of Testing Glycerine," by Prof. Richard Godeffroy, of Vienna; "On the Preservative Action of Chloroform on Infusions, &c.," by Mr. J. B. Barnes.

A SERIOUS outbreak of scarlet fever is reported in Cheshire. Weaverham, a village of 1,722 inhabitants, has had 165 cases, of which 29 were fatal; Acton 42 cases, three of them fatal; and neighbouring villages have also suffered more or less. The local sanitary authorities are said to be taking measures to prevent the spread of the epidemic.

WE understand, says *The Athenæum*, that the proceedings of the recent European Conference "On Cholera," together with the views of the President, Professor von Pettenkofer, who is also President of the Sanitary Department of the German Empire, will be embodied in a work now in the press by Professor Pettenkofer and Dr. Hime, of Sheffield. It will be published by Messrs. Baillière, Tindall, and Cox.

At a meeting of the Metropolitan Asylums Board, on Saturday, it was resolved to erect a third imbecile asylum for children. The Hampstead Committee were deputed to seek out a suitable spot of land, containing from 100 to 150 acres.

#### RESECTION OF THE LOWER JAW, LEAVING RIM OF SUPPORT.

DR. GARRETSON, in the *Philadelphia Medical Times*, publishes a case operated on by himself some five months back, in which the cure became perfect without any necrosis of a very delicate rim left, and under a constitutional condition which renders a notice of it valuable to a class of practitioners who have occasion, to be informed of precedents in such direction.

The patient, a Miss C., *ætat.* 17, of exceedingly delicate organisation and of *decidedly strumous* tendency, required operation on account of a cysto-sarcomatous tumour, which extended from the first molar tooth of the left side to the first bicuspid of the right, and which involved the body of the jaw to a depth extending midway between the dental canal and the base of the bone. Exposing the parts, as shown by the cut, with the expectation of a necessity for the full section of the bone, it was deter-

mined (seeing that the tumour might be removed and yet a rim left) to risk a return of the disease and the probability of necrosis, together with the possibility for a second operation, rather than produce, without an assured absolute necessity, the hideous deformity consequent on the complete section.

The precedent of interest in the case lies in the fact that here is another instance in which the inferior dental vessels have been removed, and a long span of bone survives, and this under most adverse constitutional condition. The patient is now perfectly well, and is without greater deformity than is seen in any person who has lost the lower teeth. The chin, of course, and the articulation of the remaining teeth have their normal relations preserved, while even the lost parts are capable of being perfectly represented in an artificial denture which I shall shortly prepare for her.

### THE DUBLIN CORPORATION AND ITS SANITARY DUTY.

In connection with their obstructive policy in reference to the Public Health Act, and their stupid inefficiency in the matter of sanitation, we have had occasion to give our readers a faint idea of the atrocious misgovernment under which the citizens of Dublin labour—misgovernment which has driven them into open revolt against the corruption and extravagance of their Town Council. At the last meeting of the Dublin Sanitary Association their attention was directed to a report of the Waterworks Committee of the Dublin Corporation, dated October 2, from which it appeared that a sum of £1,914 had been expended in promoting a private Act of Parliament in opposing one promoted by the Kingstown Commissioners, and in procuring a provisional order. Particular attention was directed to the relative cost of the private Act (£785), and of the provisional order (£1,085), and fears were expressed that unless some check be placed on the expenses of promotion, the provisions of the Public Health Act relating to provisional orders will become a dead letter.

And all this extravagant, and we venture to say, in many instances, entirely useless expenditure, at a moment when the same Corporation can spare no more than £10 a year to the working officers of the Public Health Act! With such facts before us, it is not wonderful that the Irish *Builder* should speak as follows:—

"What a miserable exhibition the work performed by the Corporation makes as against the expenditure incurred in promoting bills, paying law expenses and salaries to a needless staff of officers, as well as heavy pensions to hale and healthy public servants, who are induced to retire to make room for other hangers-on! There is not a city or chief town in Great Britain in which sanitary duties are so badly performed, though the payments to officers exceed by far that paid in other places. Were we to go through all the special and particular duties devolving upon the Corporation, the same shameful neglect could be shown; and what should be a source of profit, and what is a source of profit in other towns and cities, is in the hands of the Dublin Corporation a dead loss! The citizens are taxed to almost the confiscation of their properties to support the worst specimens of municipal rule that ever yet cursed the British Islands.

"We want still another commission—a commission that would bring with it a needful reform. If the Government by a minute of Council were to put the Civic body in commission for a year or two, a lesson would be taught that is much wanted. Short of this, however, a purification of the Town Council is urgently needed, as well as that of the Liffey; and if the citizens follow up the movement they have begun, honest and practical men will be returned as their representatives."

### THE IRISH SANITARY OFFICERS AND THEIR SALARIES.

At a meeting of the Drogheda Corporation a report was adopted, in which it was recommended that, having regard to the fact of the salaries of the officers before mentioned having been recently increased by the Poor-law guardians, and which increase was granted immediately previous to the passing of the new Sanitary Act; and further, that the Poor-law guardians, at their meeting held on the 22nd inst., declined to further augment the salaries of said officers; we would most respectfully suggest that the Council do not resolve any additional increase to the salaries of said dispensary officers. The following extract from a letter of the Local Government Board may be read in connection with the above:—

"It will be borne in mind that by the Act of Parliament it [was] provided that the local sanitary authorities should in the first instance determine the salaries, but that the power of finally adjusting them resides in the Local Government Board, subject to approval by the Lords Commissioners of the Treasury. *The Local Government Board are prepared to perform their part of this duty with a full sense of their responsibility in this matter, and under the impression that, inasmuch as the Act of Parliament has imposed on dispensary medical officers additional statutory duties, it is the business of the Local Government Board to see that proper remuneration is provided for these additional duties.*"

AN extraordinary "rig" of the market in the articles of iodine and quicksilver has been going on for a long time, and has now almost reached a climax. Quicksilver is now quoted at £25 per bottle, and is still mounting. The *Chemist and Druggist* says that Chilian iodine is now on the market in considerable quantity, and seems likely to prove a useful check on the extravagant prices which the combination of makers has at times forced from buyers.

THE Council of the Society of Arts announces that it has made arrangements for the delivering of the following courses of Cantor Lectures in the forthcoming session: "Alcohol, its Action and its Use," by Dr. B. W. Richardson, F.R.S.; "The Material, Construction, Form, and Principles of Tools used in Handicraft," by the Rev. Arthur Rigg; and "Some of the Forms of the Modern Steam Engine," by F. J. Bramwell, F.R.S.

## Correspondence.

### DR. LANKESTER AND THE CORPORATIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the biographies of the late lamented Dr. Lankester an important matter is omitted that had a great influence on his career, for it fully accounts for his not "laying himself out for practice,"—to use the words of the *Lancet*—and for his being "shut out" as Physician to St. Mary's Hospital. This, according to the orthodox system of election, after his rejection at the London College of Physicians, was a matter of course.

At this important crisis, when we are bound hand and foot to the corporations, by means of an unrepresentative Medical Council, a brief recital of the circumstances, as published by himself after his rejection, 1847, in a pamphlet now before me, cannot fail to be useful and instructive.

I give a brief outline of the occurrence which is related in the above-named pamphlet.

Dr. Lankester was distinguished for great industry and talent; he had obtained honours in ten of the classes at University College, and had contributed numerous papers to the medical journals. Dr. Lankester passed the examination for the extra (a) licence at the College of Physicians in 1841, and in 1847 he presented himself to be examined for the licence, believing that as he was a member of the College, and had passed one examination, he would only be called upon to answer "practical" questions. The doctor, however, was rejected, and the most amusing part of the affair was that one of the examiners, whom he supposed had a great share in his rejection, had six years before given him the following certificate: "*I can fully testify to his competency to fill the office of Physician to a London dispensary with credit to himself and much advantage to the objects of the institution.*" Dr. Lankester, who lectured on *materia medica*, was also examined by a rival lecturer on this subject at a neighbouring school (Parliamentary Evidence, 1847).

The subjoined is from Dr. Lankester's pamphlet:—

"If I were a young man who had only had the five years' study which the College requires, I might consistently have been sent back for a year; but what must be thought of the value of the College examination which supposes that the knowledge it requires may be got up in twelve months, but could not be gained by eighteen years of hard study and diligent observation. At the same time, however, I am not ignorant of the fact that there are gentlemen in London who in less than a year would engage to prepare me, as they have done hundreds of other members of the College, in such a manner as to ensure my passing their examinations. I have never, however, condescended to the practice of cramming in the four examinations that I had previously submitted and passed. I conscientiously regard myself at this moment as fitted to practise my profession, and if the College examinations are of a nature rather to test the schoolboy's qualifications which may be got up by a cram than those which have been gained by reading and experience at the bedside, I can only express my regret that public confidence should have been given to examinations which every member of the College must feel are not worthy of it."

Believing, Sir, that this rejection at the London College of Physicians had much influence on his subsequent career, and believing also that under the circumstances named it redounded rather to his *credit* than to his *disgrace*, I ask you to insert this letter.

Yours obediently,  
EDWARDS CRISP, M.D.

29 Beaufort Street, Chelsea, Nov. 11, 1874.

#### PEN VACCINATOR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Under the head of "New Inventions," and with the name of a "Pen Vaccinator," Dr. R. Harvey Hilliard presents to the profession, in your issue of October 28th, a new instrument for vaccination.

Permit me to point out that this so-called new invention is simply a slightly modified form of an instrument invented by myself upwards of eighteen years ago, and to which I gave the name of the "Vaccine Insitor." The only alteration effected by Dr. Hilliard appears to consist in making the shoulders of the blades broader near the points, in consequence of his adapting the instrument for scarification in place of making a punctured wound—the object for which I designed the "Insitor," for a full description and drawing of which I beg to refer your readers to the *British Medical Journal* of September 27th, 1856.

I am, Sir, your obedient servant,

GEORGE EDWARD NICHOLAS, M.D.,  
Medical Officer of Health for Wandsworth.

2 and 3 Church Row, Wandsworth,  
November 9th, 1874.

P.S.—Since writing the above, Messrs. Coxeter and Son, of Grafton Street East, makers of the "Insitor," have kindly furnished me with the subjoined drawing.—G. E. N.

(a) To practise as a physician seven miles out of London, but not within the sacred circle.

## Medical News.

**Royal College of Surgeons of England.**—The following gentlemen, having passed the required examination for the diploma, were duly admitted Members of the College on Monday, Tuesday, and Wednesday last:—

Anderson, William S., M.B. Glas., Middlesborough.  
Barlow, John, Manchester.  
Brummitt, Robert, L.S.A., Banbury, Oxon.  
Buckell, Ernest H., Chichester.  
Bull, William H., Hammarsmith.  
Callcott, James T., Newcastle-on-Tyne.  
Carey, John T., Guernsey.  
Chadwick, Alfred, Manchester.  
Cobb, Robert, Rochester.  
Collet, Golding Bird, Worthing.  
Derington, John M., Leicester.  
Eastall, Henry F., L.S.A., Blackheath.  
Ferrier, John C., Dublin.  
Fox, Richard H., L.S.A., Stoke Newington.  
Gibb, Robert C., Jamaica.  
Gill, Edmund R., L.R.C.P. Ed., Torquay.  
Hart, Philip Neville, M.B., Catton Vicarage, Norwich.  
Herapath, Charles K. C., Bristol.  
Johnston, Wingate K., Anerley, Surrey.  
Joseph, Sidney W. J., St. Leonards.  
Kebbell, William, Brighton.  
Lamb, William, L.R.C.P. Lond., Northampton.  
McCreedy, John A., M.D., New York.  
Mackenzie, John K., L.R.C.P. Ed., Bristol.  
Maples, Reginald, Spalding, Lincolnshire.  
Putts, Edward, L.S.A., Birmingham.  
Powell, Harold M., L.S.A., Wandsworth, Surrey.  
Poynder, George F., Brandon, Norfolk.  
Roe, Frederic L., Eccles, Lancashire.  
Rossiter, George F., L.S.A., Taunton.  
Rygate, Brougham R., L.S.A., Cannon Street Road.  
Sandiford, Robert F., L.R.C.P. Ed., New Ormond Street.  
Scatliff, John M. E., M.B., Brighton.  
Smith, Herbert N., L.R.C.P. Lond., Brighton.  
Squire, William, L.S.A., Hanwell.  
Stelfox, John B., Leigh, Lancashire.  
Stewart, William R. H., Weymouth Street.  
Swift, William J. C., Ely, Cambridgeshire.  
Symonds, Horatio P., L.S.A., Oxford.  
Taylor, Daniel P. H., Sierra Leone.  
Thomas, George H. W., Stoke, Plymouth.  
Tomlin, Robert F., L.S.A., Devonport.  
Treharne, John L., L.S.A., Weston-super-Mare.  
Treves, Edward, King Edward's Road.  
Whitworth, Edward, St. Agnes, Cornwall.

#### NOTICES TO CORRESPONDENTS.

OUR attention has been called to a circumstance which seems to require notice, not only on ethical, but on legal grounds. We have reason to believe that the duty of apothecary to the Galway County Infirmary has, for the last eighteen months, been discharged by a person who holds no qualification whatever, and that he is recognised and salaried as such by the Grand Jury. The circumstances of his appointment we believe to be the following: For very many years the appointment was held by Mr. Patrick Staunton, a licentiate apothecary, who died, leaving his nephew, who is now a practitioner in Galway, in possession of his business and in discharge of his official duties. This gentleman continued to act as apothecary to the Infirmary for a long period, and appeared from year to year in the list of officers of the institution. One morning, about a year and a half since, on going to the Infirmary, he found another person installed in office by order of Dr. Browne, the surgeon, without any notice whatever to him. From personal reasons Mr. Staunton has refrained from complaint, and permitted the unqualified practitioner to remain in possession; but it is not for us to allow such an act of injustice and despotism to be perpetuated or to keep silent upon an appointment which is neither legal in itself nor consistent with the just rights of the profession. We shall be glad to be enabled by Dr. Browne's explanation to modify the statement which we have made; but if it appear that our version of the matter be a correct one, we shall certainly consider it our duty to call the attention of the Apothecaries' Hall and the Grand Jury to the matter.

**EMBRUO.**—In Mr. O'Connor's letter, published in our issue of November 18th, at page 451, commencing at "In my opinion," the following should have been the order of words: "In my opinion the cause of this paradox is that during life the admixture of saliva directly neutralises, by its alkalinity, the acidity of the gastric juice; but this neutralisation takes place only on the walls of the stomach, along which the saliva glides in a quantity sufficient for that purpose; also that the gastric juice is, as it were, jettied out from its follicles by the aid of those muscular fibres which are found in the matrix of each, and thus mixes with the contents of the stomach. And again, I think that after death, if the saliva in sufficient quantity could reach the stomach, no post-mortem digestion would take place. The reasons which I

adduce in aid of this theory are—1st. Dr. Wright says the alkalinity of the saliva bears a direct proportion to the acidity of the gastric juice secreted at the same time. 2nd. Blondlot shows," &c., &c.

**MEDICAL JOKES.**—Our contemporary, the *Philadelphia Medical and Surgical Reporter*, publishes in its last a number of witticisms from the Greek of Hierocles. The following are lively specimens:—An operator, having dressed a scalp wound, laid the patient on his back and poured water into his mouth to see if the plaster was water-tight. To another of these practitioners a patient complained that he could not lie down, nor sit, nor stand without pain. "There is nothing left for you, then," said the Greek Abernethy, "but to be—hanged."

**COMMUNICATIONS, ENCLOSURES, &c.**, have been received from—Dr. Stevenson Macadam, Edinburgh. Dr. Shadd, Washington. Dr. Edwards Crisp, Chelsea. Mr. Rivington, London. Dr. Hughlines Jackson, London. Dr. Ormsby, Dublin. Dr. Kelly, Dublin. Mr. Allingham, London. Dr. Burnes, London. Mr. Milne, Dublin. Mr. Jabez Hogg, London. Mr. Homersham, Dr. Carpenter, University of London. Mr. John Hadden, Horncastle. Dr. Jukes Styrup, Shrewsbury. Mr. Ashton, Brighton. Dr. Dill, Chorlton. Dr. Muter, Kensington. Dr. Campbell Black, Glasgow. Dr. Heaton, Leeds. Mr. Walker, St. Andrew's University. Dr. Ethridge, Chicago. The Secretary of the Astley Cooper Prize Fund. Mr. Ruding, London. Mr. Davenport, London. Mr. Porteous, Glasgow. Dr. Cameron, Dublin. Mr. Peacock, Pimlico. The Registrar-General. Mr. Lawson Tait, Birmingham. Dr. Alexander Duncan, Glasgow. Mr. M. Coleman, Dulwich. Mr. Cadbury, Birmingham. Dr. Langley, London. Dr. Bayes, London. Dr. Higginson, Donaghadee. Mr. G. W. Jones, London. Dr. Handsel Griffiths, Dublin. Dr. Bathurst Woodman, Finsbury. Dr. Birkbeck Nevins, Liverpool. Dr. De Aguiar, Portuguese Embassy. Dr. Williams, Colchester. Dr. Leary, Demerara. Dr. Foster, Dr. George Harley, London. Mr. Phillips, Hornsey. Dr. Davis, Swords. Dr. Supple, Colton. Dr. Tilton, Stonehouse. #### APPOINTMENTS.

**BARBOUR, Mr. J. M.**, Fever Assistant at the Glasgow Royal Infirmary.  
**CLAYTON, N. G.**, L.R.C.P. Ed., Superintendent Medical Officer of Health and a Sanitary Officer for the Galway Rural Sanitary District.

**CUTHBERT, A. M.D.**, Superintendent Medical Officer of Health and a Sanitary Officer for the Londonderry Rural Sanitary District.

**DAWSON, Mr. J.**, a House Physician to the Glasgow Royal Infirmary.

**DOBSON, R. J.**, L.R.C.S.I., Superintendent Medical Officer of Health and a Sanitary Officer for the Mohill Rural Sanitary District.

**DUTTE, B. L.**, L.C.M., a House Physician to the Glasgow Royal Infirmary.

**EDMUNDSON, J. M.D.**, L.K.Q.C.P.I., M.R.C.S.E., Resident Medical Superintendent of the Ennisceorthy District Lunatic Asylum.

**GREENFIELD, W. S. M.P.**, M.R.C.P., Demonstrator of Morbid Anatomy and Practical Pathology to St. Thomas's Hospital Medical School.

**HAMILTON, Mr. J.**, a House Physician to the Glasgow Royal Infirmary.

**HAYES, P. A.**, L.R.C.P. Ed., L.R.C.S.I., Junior House Surgeon at the Royal Free Hospital.

**HEARN, G. M.**, L.K.Q.C.P.I., Superintendent Medical Officer of Health and a Sanitary Officer for the Bawnboy Rural Sanitary District.

**JAMISON, D. M.D.**, Sanitary Officer for the Newtownards Sanitary District.

**LIVINGSTONE, W. O.**, C.M., M.B., a House Surgeon to the Glasgow Royal Infirmary.

**MCDONNELL, CHARLES**, L.R.C.P. Ed., Superintendent Medical Officer of Health for the Glin Union.

**M'BRAID, A.**, L.R.C.P. Ed., Superintendent Medical Officer of Health for the Newry Urban Sanitary District.

**M'CORKINDALE, D. C.M.**, a House Surgeon to the Glasgow Royal Infirmary.

**MARTIN, W. B.**, L.R.C.S.I., Superintendent Medical Officer of Health for the Newtownards Urban Sanitary District.

**MUIR, Mr. M. M. P.**, Assistant Lecturer and Demonstrator on Chemistry at Owens College, Manchester.

**MUIR, W. C.M.**, a House Surgeon to the Glasgow Royal Infirmary.

**O'NEILL, P. L.**, L.K.Q.C.P.I., L.R.C.P. Ed., Medical Officer to the Workhouse Infirmary and Fever Hospital of the Athy Union, Co. Kildare.

**PINNOCK, R. D. C.M.**, a House Surgeon to the Glasgow Royal Infirmary.

**ROSS, A. M.D.**, Superintendent Medical Officer of Health and Sanitary Officer for the Ballymena Urban Sanitary District.

**RUSSELL, P. C. M.B.**, Sanitary Officer for the Lurgan Urban Sanitary District.

**SAMPSON, F. C.**, L.R.C.P. Ed., Superintendent Medical Officer of Health for the Scariff Rural Sanitary District.

**SCOTT, W. J. M.B.**, Assistant Surgeon to the Western Infirmary, Glasgow.

**SHAW, W. M.D.**, Superintendent Medical Officer of Health for the Lurgan Urban Sanitary District.

**SMITH, Mr. D. T.**, a House Physician to the Glasgow Royal Infirmary.

**SPEARING, A. M.D.**, Superintendent Medical Officer of Health for the Antrim Rural Sanitary District.

**STUTCLIFFE, Mr. W. H.**, a House Physician to the Glasgow Royal Infirmary.

**TAGERT, R. M.**, M.D., Superintendent Medical Officer of Health for the Carrickmacross Rural Sanitary District.

**TELFORD, Mr. J. C.**, a House Surgeon to the Glasgow Royal Infirmary.

**TOWNSEND, R. H. M.B.**, Superintendent Medical Officer of Health for the Ennistimon Rural Sanitary District.

**WALL, J. M.D.**, Superintendent Medical Officer of Health for the Cork Rural Sanitary District.

## Marriages.

**JACKSON—WAN-VESTRANT.**—On the 17th inst., at St. Mary's, Newington, J. B. Jackson, L.R.C.P., &c., of Birmingham, to Angela Mariana, youngest daughter of the late Ottaviano Wan-Vestrant, of Rome.

## Deaths.

**BARNES**—On the 20th November, at 81 Grosvenor Square, London, Eliza, the beloved wife of Robert Barnes, M.D.

**CRAMBERS**—On the 14th November, at Cloverhill, Sligo, James Walker Chambers, M.D., Inspector-General of Hospitals, and late of the 35th Regiment, aged 63.

**DUTTON**—On the 10th November, James Dutton, M.R.C.S.E., of Theresa Place, Hammersmith, aged 56.

**FITZGERALD**—On the 30th October, at Lahore, India, R. G. Fitzgerald, L.R.C.S.I., late of the 36th Regiment.

**HAWKINS**—On the 8th November, J. S. Hawkins, M.R.C.S.E., of Tredegar Place, Bow, aged 37.

**PEARLESS**—On the 19th November, after a few days' illness from diphtheria, Charles Durrant Pearless, M.R.C.S.E., L.R.C.P.E., of the Vicarage, Sevenoaks, aged 32.

**SURGICAL SOCIETY OF IRELAND.**—The FIRST MEETING of the SOCIETY will take place on FRIDAY EVENING, 27th NOVEMBER, 1874.

Chair will be taken at half-past Eight o'clock precisely.  
B. WILLS RICHARDSON, F.R.C.S.I., } Hon. Sec.  
HUMPHREY MINCHIN, F.R.C.S.I., }

Royal College of Surgeons, Dublin,  
25th day of Nov., 1874.

**AN EARNEST APPEAL TO CHRISTIAN CHARITY.**—

A Lady, daughter of an officer, now deceased, but who formerly held a high position in the British Army, and served his country at home and abroad for 54 years, is at present reduced to a state of the deepest distress, with four children, in consequence of the lengthened illness of her husband.

This illness, contracted abroad, has incapacitated him from supporting his family, and obliged him, through dire necessity, to seek refuge in one of the Dublin Hospitals, where he lies at present a helpless invalid.

The deceased Officer referred to was a Doctor in the British Army, and at the time of his death held the position of Inspector-General of Hospitals; his daughter, one of a large family, is precluded from obtaining relief from the Medical Benevolent Fund of Ireland in consequence of being married; whilst her husband is at present a patient in the Adelaide Hospital, and we hope soon to procure his admission into the Hospital for Incurables. For these reasons we ask your kind attention to this appeal. The smallest subscriptions will be received and acknowledged by

M. A. WARD, M.B., 1 Rathmines Road, Dublin.  
JAMES WHITE, Rector of St. Thomas's,  
15 Middle Gardiner Street, Dublin

## MALVERN COLLEGE.

This COLLEGE contains TWO DEPARTMENTS—the CLASSICAL and the MODERN. There is also a Preparatory LOWER SCHOOL.

There are Boarding Houses within the College Grounds, held by the Head Master and others of his Staff; a Gymnasium, &c.

Board and Tuition under 14, £80; over 14, £90. Non-shareholders pay an extra fee of £6. Special advantages for Sons of Clergymen and Home Boarders.

For further information apply to the Rev. ARTHUR FABER, M.A., Head Master, late Fellow and Tutor of New College, Oxford.

The Examination for Scholarships and Exhibitions on December 22nd and 23rd.

Established 1848.

**PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.**

50 LINCOLN'S INN FIELDS, W.C.

**J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.,**  
 &c. (KING'S COLL.), and Author of *VIA MEDICA*.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

**COMPETENT ASSISTANTS** provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

**PRACTICES AND PARTNERSHIPS NOW OPEN** for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

- Z 65.** In the suburbs of a wealthy manufacturing town, an **OLD-ESTABLISHED PRACTICE** for transfer, with partnership introduction or otherwise, as may be desired. Receipts, £950. Appointments, £450. Great scope for increase. Illness is the sole cause of retirement. Premium for a short introduction, £800, part of which may be paid by instalments. Additional sums, according to length of introduction or partnership.
- Z 64.** In a pleasant part of Oxfordshire. A gentleman who has a large and improving connection desires to secure the co-operation of a suitable gentleman to conduct **ONE-HALF OF THE PRACTICE**. The income was formerly about £1,000 a year, but owing to local circumstances, temporarily declined. The whole connection can be regained, and the opening presents an exceptional opportunity to secure a large practice in a good agricultural district. Appointments yield £230, and could be considerably increased. The highest references given, and easy terms conceded to a suitable gentleman with £300 at command.
- Z 63.** Within fifty miles of London, with direct rail to a town in the vicinity, a good **RURAL PRACTICE**, yielding £460 a year, but capable of considerable increase, as the incumbent is advanced in age. Appointments produce £230. The work is very light, and there is no opposition within four miles. No assistant required. Midwifery, £1 1s. and upwards. The house contains ten rooms, and can be rented with or without land. A most effective introduction can be guaranteed. Premium, one year's purchase.
- Z 61.** In the suburbs of a wealthy manufacturing town, AN **OLD-ESTABLISHED PRACTICE**, the whole of which can be transferred to a gentleman of active habits. Income upwards of £600 a year, including appointments £160. Patients middle-class. One horse and gig sufficient for the work. The house contains eleven rooms, with stabling and coach-house. Rent, £38. To a suitable gentleman the opening offers a perfectly safe pecuniary investment.
- Z 60.** **SEA-SIDE.** Receipts, £450 a year. Appointments, £250. The whole transferable to a suitable **SUCCESSOR**. One horse does the work. The residence is commodious, contains fourteen rooms, with surgery, stabling, coach-house, and garden. Rent, £30. Premium, one year's purchase.
- Z 59.** Within twenty miles of London, A **GOOD CLASS PRACTICE** in a pleasant district, and yielding £600 a year, including appointments £100. The connection lies within a narrow area, but there is considerable scope for increase, as the neighbourhood is improving. House contains ten rooms, with coach-house, stabling, &c. Rent, £50. Midwifery fees, £1 1s. and upwards; about thirty-five cases a year. The practice being select, a premium of £700 is required for the goodwill.

**THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.**

**PATRON:—H.R.H. THE PRINCE OF WALES.**

This Institution was founded in 1869, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote.

Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office,

40 MOLESWORTH STREET, DUBLIN,

W. O'NEILL, Secretary.

**XMAS ACCOUNTS.**

**MERRITT and HATCHER** send, post free, on application, a variety of Samples and Prices of **MEDICAL BILL FORMS**, by which a great saving of time in making out accounts is effected.

Merritt & Hatcher, Printers, 2 Grocers' Hall Court, Poultry, London, E.C.

**IMPROVED and ECONOMIC COOKERY.**

**USE LIEBIG**

**COMPANY'S EXTRACT OF MEAT**

as "stock" for Beef-tea, Soups, made Dishes and Sauces; gives fine flavour and great strength. Invariably adopted in households when fairly tried.

**CAUTION:**

Genuine only with Baron Liebig's facsimile across label.

**SIR JAMES MURRAY'S**

**ORIGINAL FLUID MAGNESIA,**

THE PUREST, BEST, AND CHEAPEST PREPARATION,

**HAS** been prescribed for Sixty Years as the best Remedy for Acidity, Indigestion, Heartburn, Gravel, and Gout; and mixed with his Lemon Syrup, forms a pleasant effervescent Aperient, especially for Ladies and Children.

Sold by all Chemists, in Bottles, double the usual size, at 1s., 2s. 6d., and 5s. 6d. each; and in Gallon and 2-Gallon Jars for Dispensing.

**HIS CORDIAL FLUID CAMPHOR**

is also extensively prescribed for weak nerves, low fevers, cholera, and diarrhoea. Bottles, 1s. and 2s. each.

**PURE AERATED WATERS.**

**ELLIS'S**

**RUTHIN WATERS,**

Soda, Potass, Seltzer, Lemonade

Lithia, and for GOUT, Lithia,

and Potass.

**CORKS BRANDED "R. ELLIS & SON, RUTHIN,"** and every label bears their trade mark. Sold everywhere, and Wholesale of R. ELLIS & SON, Ruthin, North Wales. London Agents:—W. BARR & SONS, Henrietta street, Cavendish square.

**MIR. I. SANDHEIM,**

### ON THE SCIENTIFIC AND EMPIRICAL INVESTIGATION OF EPILEPSIES.

By J. HUGHLINGS JACKSON, M.D., F.R.C.P.,  
Physician to the Hospital for the Epileptic and Paralysed, and to the London Hospital.

#### CHAPTER III.

#### ON CLASSIFICATION AND ON METHODS OF INVESTIGATION.

It has been said that we can best judge of a person's character by what he finds laughable. No doubt we may best judge of a man's intellect by his classifications, for, as Spencer says ("Psychology" sec. 309-316), Classification is really a process of Reasoning. When, he says, we think of the objects compared, we classify; when we think of the relations betwixt them, we reason. From a person's classifications we judge of his "form of mind." We may adapt and apply Spencer's statements thus: In Investigating cases of nervous disease, we are really Classifying them or their symptoms. From all points of view Classification is of vast importance. I shall, therefore, consider it in its most general bearings, as well as specially for the present subject of Epilepsies.

When, in the first Chapter, I spoke of the anatomical and physiological investigation of epilepsies, I mentioned that we require Clinical Entities for practical purposes. This admission was certainly contrary to the spirit of the quotations contained in that chapter. In short, since the papers quoted from were written, I have modified my opinion so far as to hold that we require two kinds of classification. I believe I have been much influenced in this matter by Dr. Moxon. The following quotation is from an article by him:—

"When we are dealing with the public or social functions of names we must keep in view the distinction between a science nomenclature and an art nomenclature. The aim of a science is the increasing and unlimited knowledge of the things it concerns itself with; a science

seeks out and names with no other object than to know. The scope of any art is, on the contrary, limited and prescribed; it has its proper sphere of work, and it must borrow from the nomenclature of the sciences which it rests upon such names only as are useful for its practical purposes. Two opposite principles, then, must govern the construction of a nomenclature for use in an art such as that of medicine. These principles are—

"First. That every subject which it is important that the followers of the art should be able to mutually recognise, or to communicate to each other, should be embodied in a distinct and suitable name.

"Second. That names should not be introduced into the nomenclature of the art except on account of their applications to subjects of practical importance in the purposes of the art.

"Another and a very obvious principle is, that the names adopted should be so far carefully chosen that they may not contradict or misrepresent the actual facts of the subjects to which they are applied." (Dr. Moxon, "On the Necessity for a Clinical Nomenclature of Disease," "Gay's Hosp. Reports," vol. xv., p. 482.)

We are in medical art and science, as in other arts and sciences, obliged to make arbitrary divisions where there are no clear divisions in Nature. Thus, at the close of the last chapter, I spoke of the arbitrary standards medical men make for describing cases in which there are different degrees of affection of consciousness ("confusion," "stupor," "loss of consciousness," and "coma"). There really occur all shades of affection of consciousness (see page 411, and also further in this Chapter). But such arbitrary divisions as those just mentioned are absolutely necessary for clinical purposes. Let me give another illustration; I have a double purpose in giving it.

There are from lesions of different degrees of gravity in and of the cerebral hemisphere, near to the corpus striatum all degrees of defect of language, from a slight ataxy of articulation to a state in which there is loss of all power of expression, whether active (intellectual), or passive (emotional). For this reason I have strenuously objected to the abrupt divisions made by nosologists. The divisions usually made are exceedingly

abrupt, passing from physiology into psychology at a bound (ataxy of articulation—anatomico-physiological phraseology—and “loss of memory for words”—psychological phraseology). But I found that I was making arbitrary divisions too. I found myself speaking of “an ordinary specimen of loss of speech.” Whilst as strongly as ever I believe that from different degrees of damage of the left corpus striatum and adjacent cerebral hemisphere there result all degrees of defect, from a slight ataxy of articulation to entire loss of power of expression, I admit that we must have arbitrary divisions of affections of language for clinical purposes. For all that, I insist that the classification of defects of language on a mixed method of physiology and psychology is an illegitimate one. To remark on this point is my chief reason for giving the illustration. Where the expression “loss of memory for words” would be used I should say there is “defect of speech,” or that the patient “makes mistakes in words.” These simpler expressions are really quite as definite, though they sound less definite; they have no technical ring. It may be said that they amount to the same thing. Practically they do not; they have no psychological associations. The expression, “loss of memory for words” takes the symptom out of the category of such other nervous symptoms, as hemiplegia. For there is no conceivable community betwixt loss of “memory” and loss or defect of “movement,”—betwixt “loss of memory for words” and ataxy of articulation—not enough in common as a basis for the widest contrast.

I must, indeed, at the beginning of a Chapter on Classification, urge strongly that we are to rid ourselves as much as possible of psychological bias in what is an anatomical and physiological inquiry. I do not mean that we have no concern at all with psychology. On the contrary, it is perfectly obvious that it is impossible for us to begin to study the anatomical *substrata* of mind without prior psychological analysis.

On this matter I will quote Mill: “And even if that hypothesis [phrenological] were true, psychological observation would still be necessary; for how is it possible to ascertain the correspondence between two things by observation of only one of them? To establish a relation between mental functions and cerebral conformations requires not only a parallel system of observations applied to each, but (as M. Comte himself, with some inconsistency, acknowledges) an analysis of the mental faculties.” (Mill on “Comte and Positivism,” p. 66.)

But I urge again that our concern with states of mind is indirect. We start with the assumption that all mental states have material bases, and our direct concern in such an inquiry as this is with the latter only. Clearness on this matter is of very great importance for our subject, and of immense importance when speaking of classifications and methods of investigation of diseases of the higher nervous centres.

There are two ways of investigating diseases, and two kinds of classification corresponding thereto, the empirical and the scientific. The former is to be illustrated by the way in which a gardener classifies plants, the latter by the way in which a botanist classifies them. (a)

The former is, strictly speaking, only an arrangement. The gardener arranges his plants as they are fit for food, for ornament, &c. One of his classifications of ornamental plants is into trees, shrubs, and flowers. His object is the direct application of knowledge to utilitarian purposes. It is, so to speak, practical. The other kind of classification (the classification properly so-called)

(a) “Each science or art forms its classification of things according to the properties which fall within its special cognizance, or of which it must take account in order to accomplish its peculiar practical end. A farmer does not divide plants, like a botanist, into dicotyledonous and monocotyledonous, but into useful plants and weeds. A geologist divides fossils, not like a zoologist, into families corresponding to those of living species, but into fossils of the palæozoic, mesozoic, and tertiary periods, above the coal and below the coal, &c. Whales are or are not fish, according to the purpose for which we are considering them.” (Mill’s “Logic,” vol. i., p. 275.)

is rather for the better organisation of existing knowledge, and for discovering the relations of new facts; its principles are Methodical guides to further investigation. It is of great utilitarian value, but not directly.

The difference here is plain, because the gardener and the botanist are different persons. But in our profession, the same person has to Classify for the organisation and advancement of his knowledge, and to make an Arrangement for direct utilitarian purposes of daily life. The reader will now see that there was no cynicism intended in the illustration just given. We require two classifications, or rather an arrangement and a classification. An arrangement corresponding with that of the gardener is essential for the practice of our profession. It is a technical or artificial classification. A scientific classification is necessary for the organisation and development of our knowledge of disease. It is a natural classification, and is thus a means of investigation.

We require for practical purposes types as foundations for arrangement. (a)

On this subject I shall quote largely from Handfield Jones (*see* Appendix). We require clinical entities, such as locomotor ataxy and idiopathic epilepsy. As the matter is one of exceeding great importance, I will illustrate the two kinds of classification, or, what is fundamentally the same thing, the two methods of investigation by several examples. Some of them are purposely taken from cases of other nervous diseases or symptoms than those resulting from epileptic discharges.

In a case of disorderly walking we endeavour to determine whether the gait resemble that which authorities have described as the gait of typical Locomotor Ataxy, or that of typical Cerebellar Reel. We might conclude from examination of a case as follows: This patient has tumour of the cerebellum, because (besides having severe pain in the head and double optic neuritis), whenever he walks, he walks with his legs apart, and reels from side to side or from back to front—walks as if drunk; he has no ear disease. This is the empirical or clinical study. Scientifically, we seek to know in what way the patient’s walk differs from healthy walking. To say that it is a difficulty in co-ordinating the movements of locomotion is a merely verbal explanation; it is objectionable as an explanation. But clinically, as distinguishing the motor symptoms from paraplegia, the nomenclature is useful. The “explanation” is given in the untechnical statement that “the patient reels.” The scientific investigation would demand prior knowledge of the play of the muscles of the trunk and legs in the various positions of healthy walking. It is a study of symptoms and diseases as they show departures from healthy states; this is only another way of saying that it is a study of cases as anatomical and physiological experiments on the nervous system. The reel would be—this is my belief—found to be a departure from healthy walking on account of feebleness of movements of those muscles which brace up the spinal column. Assuming the correctness of this explanation, we can make the more scientific use of the case. We see more clearly the affinities of the reel; we see that being, dependant (b) on palsy it is far more like hemiplegia than, for example, like chorea. In fact, the hemiplegic man has lost a certain number of “co-ordinations of movements” of his face, arm, and leg of one side. The patient who reels from disease of the cerebellum has lost a certain number of “co-ordinations of movements” of his spine, and later on in the disease, of his legs. On the empirical or clinical view, this is not manifest; indeed, the reel and chorea are often spoken of

(a) “By a type, Whewell meant a well-selected average member of a class, removed alike from all extremes, a concrete embodiment of the class, to be used for purposes of identification in preference to any verbal definition. The motive was the existence of *anomalous* members of many groups in Natural History.” (Bain’s “Logic,” Induction, p. 191.)

(b) I say “dependant on,” as no doubt there is a compound defect from the spinal paresis, just as there is from paresis of an ocular nerve. (*See* foot-note later, on Vertigo.)

as if they were similar disorders of co-ordination. Their resemblances are most superficial; they are fundamentally different, not only in the very superficial way that they are affections of different regions of the body, but in that the central changes in one are those of loss of function (a palsy), and in the other those of over-function (owing to a "discharging lesion"). Thus considered, the case can be compared with tetanus, just as a case of hemiplegia can be compared with a case of hemi-spasm. In tetanus there is a discharge first and most upon those muscles which serve first and most in locomotion, that is, upon the muscles of the spine and legs and upper parts of arms—that is upon those muscles which are first and most affected in the Cerebellar Reel.

Let me now illustrate the differences by taking a series of symptoms belonging to our subject. I believe that epileptic vertigo, epileptic *petit mal*, and epileptic *grand mal*, are, when regarded from an anatomical and physiological point of view, simply differing degrees, that is to say, that they depend on different strengths of discharge, beginning in and spreading from the same parts of the brain. The discharge in each begins in the very highest centres of the cerebral hemispheres, that is to say, in the anatomical substrata of consciousness. If it be very slight there is vertigo only, if stronger there is loss of consciousness, and if very strong there is convulsion also. This is the scientific classification and method of investigation. (a)

The relations betwixt loss of consciousness and convulsion have already been spoken of implicitly in Chap. I., Pt. II., p. 349 and 350, and explicitly in Chap. II., p. 410. We now speak more in detail, and take into consideration the third symptom—vertigo. Vertigo, like convulsion, is a motor symptom, and since in *petit mal* there is loss of consciousness, the statement that there are degrees betwixt epileptic vertigo, *petit mal*, and *grand mal*, may seem at first glance strange. Let us consider the question raised.

A word, says Lewes, is not only a symbol of a thing, it is also a centre of association. The expression "loss of consciousness" has evidently very strong psychological and very slender physiological associations; what it automatically arouses are chiefly thoughts about "memory," "volition," "will," &c. Thus, there is a feeling that comparisons such as the one spoken of are comparisons attempted betwixt mental states and physical states. But the associations which the expression "loss of consciousness" should arouse in an inquiry like this, are thoughts of other nervous symptoms, which thoughts would lead to such comparisons as those of morbid conditions of the material basis of consciousness with those conditions of inferior centres which cause other nervous symptoms. We have to deal with loss of consciousness as a symptom due to implication of nervous centres which are, except in degree, just like other nervous centres. The centres which are the anatomical substrata of consciousness also represent impressions and movements, or rather, they represent in greater complexity, &c., the impressions and movements represented in all lower centres, being evolved out of those centres. They thus represent the whole organism, and represent it as a whole in adjustment to its environment. On this basis the comparison is legitimate. Physiologically, loss of consciousness is a loss of adjustment of the organism as a whole to its environment, being a loss of use of the nervous processes by which that adjustment is made. Vertigo is a defect in that adjustment; it is a motor symptom. It is in this way that we trace its relations through loss of consciousness to convulsion.

If we consider the facts of the vertigo attending palsy of the ocular motor nerves, we see plainly that it is a motor symptom. (b) It is, however, sometimes spoken of as a sen-

sory symptom, because a "sensation" (a) attends it. It is one of those disorders of co-ordination which has a subjective side. But the "sensation" in this case is a state of mind (see Chap. I., Part 2, page 349), and states of mind may arise during energising of motor as well as of sensory nerves and centres. Our direct concern is with the physical process which goes on in the nervous system whilst the "mental state" which is a feeling of vertigo continues; it is the physical process which is a disorder of motion—actual or nascent. There is as much difference betwixt the sensation or feeling the giddy man has and the physiological process which goes on in his nervous system as there is betwixt pain and the changes in the sensory (afferent) nerve which exist whilst the pain lasts, or as there is betwixt the colour red (b) and the change in the optic nervous system associated with it.

Hitzig's researches on galvanising the cerebral hemisphere in man (the electrodes being applied to the outside of the head) show clearly, I think, that vertigo is on its physiological side a motor symptom. An account of these experiments is to be found in the third edition of Althaus's "Medical Electricity," page 141, from which I borrow the facts below given. Hitzig distinguishes three degrees of vertigo: a slight current produces no outward effects, but there is a feeling of uncertainty as regards the position of one's body, or of external things; in the second there is no outward effect, but there is a feeling of movement; in the third degree the patient actually does turn. These experiments, taken with clinical facts, show that epileptic vertigo is on its anatomical and physiological (or objective) side a unilateral disorder of motion; or, otherwise expressed, that it is a particular defect in the adjustment of the organism as a whole to its environment. In the first and even second degrees of "galvanic giddiness" there is only faint excitation of those centres which, when strongly excited (third degree), cause actual movement. (c) So in calling "galvanic" or epileptic vertigo a unilateral disorder of motion one means that it is

supposed. It is owing (1) to erroneous estimation of the position of external objects, or, speaking technically, to "erroneous projection," and (2) to over-action of associated muscles. In this principle we have the full explanation of the Cerebellar Reel, the Ataxic Stagger, and some other "disorders of co-ordination," dependent, as I believe, on palsies or paresis of motor nerves and centres.

It may seem that I am trying to prove in the text that partial loss of consciousness is a state of mind—i.e., that partial loss of consciousness is a state of consciousness. There is really in what we call defect of consciousness, a double state; the "mental state" may be partly due to over-action of subordinate centres, from loss of control, by defect in their highest nervous centres. I shall consider this principle, already several times referred to, later on. There is a duality in the anatomical substrata of consciousness; diminished "object consciousness" is constantly attended by increased "subject consciousness."

(a) "These [mental phenomena], according to the classification we have uniformly followed, consist of Thoughts, Emotions, Volitions, and Sensations, the last being as truly states of Mind as the three former. It is usual, indeed, to speak of sensations as states of body, not of mind. But this is the common confusion of giving one and the same name to a phenomenon and to the proximate cause or conditions of the phenomenon. The immediate antecedent of a sensation is a state of body, but the sensation itself is a state of mind." (Mill's "Logic," 8th ed., vol. ii., p. 436.)

(b) "Let it be shown, for instance, that the most complex series of physical causes and effects succeed one another in the eye and in the brain to produce a sensation of colour; rays falling on the eye, refracted, converging, crossing one another, making an inverted image on the retina, and after this a motion—let it be a vibration, or a rush of nervous fluid, or whatever else you are pleased to suppose, along the optic nerve—a propagation of this motion to the brain itself, and as many more different motions as you choose; still, at the end of these motions, there is something which is not motion, there is a feeling or sensation of colour. Whatever number of motions we may be able to interpolate, and whether they be real or imaginary, we shall still find, at the end of the series, a motion antecedent, and a colour consequent." (Mill's "Logic.")

(c) Excitation of motor centres suffices to give us ideas of movements, even when the motor organs have been removed. (See foot-note (a), Chap. I., Pt. 2, Oct. 21, 1874, p. 349, and Weir Mitchell on Faradising Stumps, *op. cit.*)

(a) As will be pointed out later on, authorities declare that, to use the words of Niemeyer, "there are many intermediate stages between epileptic vertigo, the *petit mal*, and complete epilepsy." But the assertion in the text is that they are different degrees depending on discharges of different strengths beginning in the same part.

(b) The giddiness is not due to double vision, as is often

essentially so; there is nascent or incipient movement in the slighter discharges, and actual movement in stronger discharges.

Vertigo, a motor symptom, has a subjective side in the feeling, or "sensation" of confusion. This is really a *defect of consciousness*. Loss of consciousness in the stronger discharge occurring in cases of *petit mal* is on its physiological side a loss of adjustment to the environment.

I nevertheless, in spite of these fundamental resemblances, consider that some such arrangement as that into the three Clinical Entities is necessary for practical purposes. Our patients consult us for symptoms. A man comes to us for vertigo, and we have to find out whether it is epileptic vertigo or not. For this purpose the empirical classification or arrangement is the best. For example, a patient having an attack of vertigo, it is important first to consider it as vertigo simply, in order to ascertain whether in its superficial features and circumstances it corresponds to epileptic, to aural, or to so-called stomachic vertigo. We thus identify it, and can afterwards trace its fundamental associations. Again, if a patient temporarily loses consciousness, we have a similar investigation to find out whether it be *petit mal* or ordinary fainting. Thirdly, if there be convulsion, we try to determine whether there be apoplexy, uræmia, tumour, &c. It may be well to illustrate this point at more length. Let us take a really difficult case. We will not suppose that a man comes telling us he is subject to *convulsive seizures*, but that a patient is brought by the police to our hospital for a fit which happened in the street. We should take note of the prominent facts, of the convulsion, with loss of consciousness, followed by coma, and with bitten tongue. We should in our minds make a rapid clinical arrangement of the conditions under which such convulsions occur. If the convulsion had been universal, and if there were no paralysis after it, we could not tell (I mean from the condition of the patient) whether there was uræmia, cerebral hæmorrhage, or tumour. For the epileptic fit (I now mean the *grand mal* of authorities) may not differ from the convulsion in some cases of uræmia, in some cases of cerebral hæmorrhage, and in some cases of intra-cranial tumour. If from the patient's age, and from an examination of his eyes, arteries, urine, &c., we could eliminate uræmia, cerebral hæmorrhage, and tumour, we should in all probability be right in saying there was epilepsy *grand mal*. (a)

(To be continued.)

## THE CURE OF BENT KNEE AND THE IMMEDIATE TREATMENT OF CONTRACTED JOINTS.

By J. MORGAN, M.D., F.R.C.S.I.,

Surgeon to Mercer's Hospital, Professor of Surgical and Descriptive Anatomy to the Royal College of Surgeons, &c.

In continuation of my observations, I may here introduce the method adopted as a bone-setter's method, taken from Mr. Hood's book.

The operator, as will be perceived, grasps the heel of the patient between his knees, the inner condyles resting on its sides just below the ankle-joints. By this means the foot serves as a lever to rotate the leg; the hands grasp the knee and the thumb is situated upon the painful point, which, in bone-setter parlance, is where the "bone is out." The operator then rotates the leg by a lateral movement of his thighs, and then directly flexes it by the movement of the hands and thighs together; this movement can only carry flexion to a certain point: as soon as this limit is reached he relinquishes his original grasp, and places his right forearm near the wrist under the knee as a fulcrum, grasps the leg near the ankle with the left hand, and flexes to the full extent. From this description it will be seen that the method originally

(a) The diagnosis is really more difficult, but the above will suffice for illustration. Of course, if we had a history of fits, occurring now and then for months or years, or if we waited until the patients recovered consciousness completely, we should practically have the diagnosis made for us. If the fits were one-sided the difficulty would be a little less.

suggested by Hey for his internal derangement of the knee-joint (often so obscure an accident) is simulated; and, therefore, in such obscure cases success would follow this action and the application of the thumb to the painful point; while in cases where adhesions had existed, the active flexion and "twist" of the joint would at haphazard break through those that had impeded its motion, and thus liberate a limb which had long given inconvenience and concern.

Fig. 6.—Mode of manipulation and thumb-pressure combined.

The knee being now straight—in the case I have detailed—I laid it in a well-prepared splint, having padded the joint round with wadding, I gave an opiate that afternoon, and let the child gradually recover, as already detailed, with perfect results.

In this instance I did not use passive movements to obtain a very movable joint, as, from the long standing of the disease, I did not anticipate much immediate results as to motion. I put on a lateral support, leaving the motion to be regulated more at the child's will, and by degrees. Every day showed an improvement. But were the adhesions more recent, I would, after a few days, have used gentle passive motion, by swinging the limb, or otherwise. As inflammation might be more apprehended in such recent cases, it may be well to keep pounded ice or evaporating lotions round the joint, and use every reasonable precaution against inflammatory action being set up. The small amount of pain that was experienced after the extension of a joint so long tied together was in the case detailed and in other similar instances remarkably little, so much so indeed that we might almost believe in the assertions that persons who submitted themselves to the operation as cripples walked to their homes.

The amount of extension to be used, it will be observed, was such as sufficed to straighten the limb. I felt, as I have stated, the adhesions give way freely—first, on increased flexion, and then on extension being made carefully, and with more or less a series of quasi jerking motion than of a violent snap. If the joint is to be straightened at all, it had best be done thoroughly, and have the adhesion fully disrupted; half doing so, or fiddling with it, tends but to irritate and set up renewed inflammatory action. It is best to have these adhesions torn, not stretched, which would only enable them by-and-by to re-establish the inconvenience it is sought to annihilate. This, indeed, seems to be in a great measure the advantage of the "bone-setter," who, being professionally irresponsible, and ignorant of the dangers of joint disease, does not hesitate to rupture fully any obstructions to motion. Mr. Hood remarks on this subject:—"The chief thing necessary is to have confidence, and to exert sharply and instantaneously the full leverage given by the limb. If the operator attempts to move slowly, he will probably in many cases stop short of doing good, i.e., of rupturing the adhesions. A timid operator may easily do mischief by traction upon joints, which after all he fails to relieve, when a bolder and more rapid movement would at once have set the patient free. I am dis-

posed to think that much of the fear of articular inflammation entertained by surgeons is based, if upon clinical facts at all, almost entirely upon the results of motion of an inefficient kind sufficient to increase the hurtful traction of an adhesion, but insufficient for its destruction." The remark made on these occasions when an adhesion is broken through, "Did you hear that?" fully explains the practice. The result is a matter for observation.

Another very successful case will form a good illustration of the advantages of this method of treatment:—**E—B—**, a girl now aged sixteen, when but a child of five years, first suffered from symptoms of "white swelling" of the knee; it eventually suppurated, and after a long contest with the disease, during which amputation was suggested on more than one occasion, the limb recovered in a state of ankylosis, as shown in the illustration, representing the patient on August 7, 1874. It will be seen that even the preposterously increased cork sole was inefficient. There was now eleven and a half inches space between the toes and the ground when the girl stood up, and even with her crutch and the immense sole to the boot she could not walk.

Fig. 7.—Case of E. B., showing the position of the limb on August 7, 1874, as it had existed for eleven years.

For eleven years this girl had suffered from this bent knee. Her form was becoming disfigured, and her health impaired. On examination I found that a certain amount of flexion remained, but that extension was impossible. I put her under the influence of ether and tenotomised the inner hamstring, and immediately closed the slight wound made. I could find that one great obstacle was at once overcome; then by the aid of an assistant and my own effort, while grasping around the joint firmly, as I have represented already, I extended the limb, and felt very firm adhesions break down within the joint. I thus could bring the limb all but straight. I then laid it in a comfortably-prepared splint, and bandaged from the foot upwards. In eight days, not being quite satisfied with the appearance, I again etherised her, and by force straightened and broke down some adhesions which still remained, and again replaced the limb. The adjustment was not disturbed for six days, and in three weeks she was walking about, resting on the sole of the foot. She has been going about the house up and down stairs, and now (in October), can walk as well almost as ever, though she prefers wearing slight supports to the joint, consisting simply of two lateral iron rods fitting into sockets at the sole of the boot, with a leather support over the point of the knee. The joint has recovered a wonderful amount of motion, and the support

is not really required, but she prefers it, as giving confidence while walking. The illustration, drawn in October by Mr. Oldham, shows the present appearance, the shaded point indicating where the abscesses originally pointed.

Case of E. B., as she stood in two months after cure by extension. Drawn October 5, 1874.

Here again the most satisfactory results were obtained. A member which had been useless for eleven years was made in a few weeks nearly as perfect as ever—without bloodshed, long confinement, or the use even of complicated apparatus, the crutch and preposterously soled boot being kept now as cherished curiosities only.

In June 1873, a country girl, aged seventeen, was sent up to Mercer's Hospital for treatment, suffering from a bent knee for six years, the result of similar disease. No abscesses had formed in her case, but the the joint was firmly fixed at nearly a right angle, and she could not put the foot to the ground, a crutch being essential to her. As her existence depended on her exertions, she was most anxious that something should be done to regain the use of her limb. I found the inner hamstring very resisting. On June 12, 1873, she was put under the influence of ether, the hamstring tenotomised, and extension was made as in other cases I have detailed. The adhesions were felt and heard giving way "crack, crack," and the limb was straightened at once, then laid on a splint, and in three weeks the girl was walking fearlessly along. She left hospital on July 9, 1873, and shortly afterwards wrote up, expressing her gratification, and saying that she was able to go about without inconvenience, beyond slight stiffness, and without a stick or crutch.

On October 21st, 1874, I extended the joint of a girl, aged nearly sixteen, who had not put her foot to the ground for eight years, but constantly used a crutch. She had first suffered when between six and seven years of age from white swelling of the knee-joint. Very firm adhesions had formed, as indicated by the feel, and by the fact that while extension was almost lost, flexion was also extremely limited, and the tension of the hamstrings had little or no influence on the deformity: as the girl had grown rapidly during the long period of inutility of the limb, the leg had wasted, and its nutrition suffered so far that it was smaller and shorter, from the head of the tibia to the sole, than the opposite leg, by nearly two inches, while the angle formed was, as shown by the tracing, very considerable. The patella was evidently bound to the condyles of the femur, while, however, a certain amount of "spring" existed between the femur and tibia. The latter had also yielded backwards from the femur. I believed that if bony ankylosis had formed it was between the patella and femur alone. I could not expect in this case,

as the leg was smaller and shorter than its fellow, so good a result as in the preceding cases.

On October 21st, 1874, I put the patient under ether, and getting one assistant to extend the leg, and another the thigh, I myself grasped around the knee-joint. I found, as extension proceeded, that the semitendinosus became

Fig. 9.—Appearance of the knee joint on October 21, previous to operation.

an opponent. I divided it with the tenotome, and closed over the wound with plaster, and I then made powerful traction from behind forwards against the head of the tibia, which from its having already gone backwards from the femoral condyles, I carefully guarded from further dislocation. I rested the patella against my chest; after a moment or two the adhesions were felt giving way freely, and the limb was straightened as far as the altered position of the tibia allowed. A gutta-percha splint was laid on the back, and bandaging put on from below upwards. Cold lotions were applied to the joint in the succeeding twenty-four hours, fearing any inflammatory action after the disruption of such long-existing extensive adhesions. No inconvenience followed.

In this instance I do not anticipate that mobility to any great extent can return to the joint, and the straight position only can be maintained, and will leave about one and a half inches of shortening, which can be replaced by a

Fig. 10.—Appearance of the limb on October 0, 1874, with the knee joint rectified.

thickened sole. I saw this girl stand with her foot laid flat down in six days after my operation of extension, as shown in the drawing taken by Mr. Oldham.

But in younger patients, as Mr. Barwell remarks, "the epiphysis of the tibia, which has not united, may be broken through and the leg brought into the same line as the thigh, the upper end of the diaphyses will then rest against the edge of the epiphyseal end, and the limb will be only shortened by little more than an inch." In Fig. 5 will be seen the mode of drawing on the dislocated epiphysis should occasion arise. In all cases the ultimate object to be gained should be predetermined by the operator. Should it be found that fibrous bands alone, which yield with tolerable ease, constituted the obstruction, then, after their disruption, motion, to a greater or less extent, should be sought to be obtained, and often in the smaller joints will be restored to an incredible amount. On the other hand, if the union be found to be dense and resisting, and to have resulted from a long-continued form of disease, the patient and surgeon may be fairly satisfied with a more limited area of motion, or even with a stiff joint brought, however, into so favourable a position that it will convert a useless and inconvenient appendage into a limb capable of supporting the weight of the body and of being used satisfactorily in progression. In cases where extensive disruption has been established, it may be judicious to put the limb in a gutta-percha or other splint which had been previously moulded to the distorted joint, and to apply cold lotions or pounded ice should any inflammatory action ensue, and after a few days to lay the limb in the more extended posture, using passive motion from day to day. I think patients will, however, regulate the amount of motion for themselves, if a lateral support, with a band across the joint, be supplied them for a short time. No definite rule can, however, apply to each case; discretion and experience must guide the way.

#### ON THE TREATMENT OF FISTULOUS SINUSES BY MEANS OF THE ELASTIC LIGATURE. (a)

By W. ALLINGHAM, F.R.C.S.,  
Surgeon to St. Mark's Hospital, &c., &c.

IN February of 1873, Prof. Dittel, of Vienna, made a communication to the Imperial Medical Society of that city on the advantages of the india-rubber ligature over other means in the treatment by operation of several surgical affections. At that time Prof. Dittel thought he was the originator of the method he described and advocated, but subsequently he discovered, or was informed, that Dr. Grandesso Silvestri, of Vicenza, had proposed a similar procedure, and even carried out some operations in the year 1862, or more than ten years prior to Prof. Dittel.

It also appears that a much honoured Fellow of this Society, Mr. Henry Lee, had read a paper in the year 1870, at the Medico-Chirurgical Society, on the use of an elastic ligature in the removal of nævi, and further, that at the same meeting, Mr. Holthouse claimed priority for himself, having, he said, employed the elastic ligature in cases of fistula in ano, and for the division of bridges of skin between fistulous orifices. Admitting, therefore, as Prof. Dittel immediately and most readily did, when the facts were brought to his cognisance, that he was not the originator, still, whatever credit may be due to the method must really be ascribed to Prof. Dittel, as the man who, by a series of experimental operations, showed what really could be accomplished by the ligature; in fact, he has done what had evidently never even been dreamed of by those gentlemen who employed it before him.

After reading myself Prof. Dittel's paper, I came to the conclusion that, assuming his statement of facts to be worthy of credence—and there was every reason to believe

(a) Read before the Medical Society of London, November 2nd, 1874.

them to be so—we might find in the india-rubber ligature a valuable addition to our usual modes of operating, and very importantly so in that branch of surgery to which I had paid especial attention. I was perfectly willing to make every allowance for the enthusiasm of the originator of any novel proceeding, and did not expect wonderful results from the ligature; most certainly I did not imagine for a moment that it would ever supersede the knife in the vast majority of cases, although I thought it might replace it with advantage under some special conditions. I was also perfectly aware that the objection that the method was unscientific might be advanced against it, and also that it essentially lacked the brilliancy pertaining to operations by the knife; but looking rather on the practice of surgery as an art than as a science, and considering that the first and great object of a surgeon's life should be to cure, and further that he should try to cure as quickly, pleasantly, and as safely as possible, I determined to fairly test the elastic ligature in what I thought suitable cases, feeling my way to more important attempts should I find encouragement to do so. Most of you, I dare say, well know how accidentally Prof. Dittel discovered in what a facile way a thin india-rubber cord could cut into dense tissues, even solid bone, and that in the elastic nature of the ligature resides its peculiar power.

Ligatures of thread for a great many years, even, we may say, from the time of Ambrose Paré, have been employed for cutting through certain structures, mainly arteries; but hæmorrhoids, nævi, warty and pedunculated growths have constantly been removed by the application of a ligature, and the reason it has not been more extensively available has arisen from the fact that only a comparatively limited thickness of tissue can be cut through by one application of the ligature, which, as suppuration takes place, becomes loose, and then does not penetrate further unless it be retightened; it is only therefore small and soft growths that can be safely and advantageously treated by the thread ligature.

Various means have been devised to overcome this inherent defect, and make the thread ligature cut, by constantly or frequently tightening the thread—such means are shown in Ricord's instrument for the treatment of varicocele; Mr. Luke's double screw, which he invented for cutting through rectal fistulæ which ran so high up the bowel as to be considered dangerous of division with the knife. A variety of methods, of which a spiral spring is the essential, have also been employed, from the using of a wooden spiral-spring letter-clip up to the very ingenious sarcoctome of Dr. Ainslie Hollis.

To all these methods, comparatively good as they may be, some very strong objections may be raised. From considerable experience, I know that Mr. Luke's double screw, valuable as it has proved, causes very intense pain; the daily or frequent necessity for tightening the ligature inflicts upon the patient a torture often unendurable, and on many occasions the knife has had to complete what the ligature began, the patient being unable to endure the long-continued suffering. Another very grave objection to the intermittent application of pressure is the frequency with which secondary abscesses result. I have had this not uncommonly occur in my own practice, and seen it also in that of other surgeons.

Dr. Hollis's ingenious sarcoctome is very superior to the others in its action, but even this requires tightening or re-setting from time to time; it acts also only in one direction, and therein lacks the even circular pressure exerted by the india-rubber. Another important objection is its size and weight, which render it, under many conditions, inapplicable; and lastly, its expense is very considerable, and you would require quite a stock of them if you wanted to use the instrument frequently.

It must be evident, on reflection, that the pressure of the india-rubber band or loop is not always the same during all the progress of the cutting; in fact, it diminishes gradually as the loop of the ligature becomes less in circumference: but practically, the pressure up to the moment

of separation, if properly adjusted at first, is sufficient for its work.

The utmost pressure exerted by a solid india-rubber ligature of the thickness of 1-10th of an inch, stretched to the utmost, only equals  $2\frac{1}{2}$  lbs. weight; for example, 6 inches of india-rubber, when stretched to its utmost, i.e., 3 feet, exercises a power of  $2\frac{1}{2}$  lbs.; when stretched to 2 feet, only a little more than  $1\frac{1}{2}$  lbs.; and when stretched only 1 foot, or double its length,  $\frac{1}{2}$  lb.; and even this power is quite sufficient, as shown by experiment, to pass through any ordinary tissue, in consequence of its unremitting and even pressure in every direction. In my experience, now, I do not think it necessary, or even desirable, in ordinary tissues, to fix the ligature so tightly around the part to be severed as I formerly did. I believe a slighter equable pressure will effect safely and more painlessly all we require. In fact, the elastic ligature does not so much cut as gradually compress and render dense the part contained within the loop, and this is how its action differs from inelastic ligatures—ulceration taking place on both sides of the loop, so that when the ligature comes away, actually a portion of the tissue is found contained in it; so hard, dense, and semi-transparent is this as to resemble horn. (Specimens illustrating this were shown to the Fellows.)

In my earlier operations I used a small drainage-tube, tied in a reef-knot, as recommended by Prof. Dittel; this does not answer so well as the solid india-rubber used by Sir Henry Thompson, and I never now tie a knot, as the knotting very easily breaks the india-rubber; but I adopt a plan I will presently describe. In my early cases, when employing the drainage-tubing, I twice had to tighten the ligature, as I thought it was not exercising sufficient pressure; but I now know this need scarcely ever be done if the ligature be properly adjusted at first.

I am myself thoroughly convinced that there are decided advantages in the india-rubber ligature over the knife in many surgical cases: it is my intention to-night to confine my remarks specially to the subject of its use in sinuses; but I may mention that I have an experience of the ligature in sixty operations, the characters of which I will only mention—viz., twenty-eight cases of fistula in ano at St. Mark's Hospital, and twelve in private practice; five cases of hæmorrhoids; two cases of sinuses in the groin, one in the neck; two removals of scirrhus breasts; two cases of pedunculated tumours (one case of my own, the other Mr. Shillitoe's, who applied the ligature at my recommendation, and with my assistance, and with excellent result); two cases of varicocele; two of varicose veins; one division of the sphincter ani muscles, in case of great tendency to hæmorrhage; two cases of linear rectotomy; one nævus. In none of my cases has there been any serious "contre-temps." I have only once seen a secondary abscess follow the ligature. I have never had a case of erysipelas, and the resulting wounds have been uniformly remarkably healthy. Many of my cases at St. Mark's Hospital were treated when the hospital was by no means in a good hygienic condition; but all my ligature wounds went on well, and generally were much healthier than the wounds in patients in adjoining beds that had been made with the knife. I frequently showed to gentlemen who accompanied me round the wards my cases of ligature doing perfectly well, and my incision cases very much the reverse, although precisely the same after-treatment had been adopted in each—viz., the application of carbolic oil. Our resident surgeon, who of course had the opportunity of watching the cases day by day throughout the treatment, often commented on how much better the ligature cases did than the others. Here I must mention that I did unfavourable as well as favourable cases with the ligature (three of my twenty-eight hospital patients were decidedly phthisical), and when occasion presented, I chose two patients whose cases were as much alike as possible, the patients being also nearly of an age, both healthy-looking, and as far as one could judge, both likely to do equally well. The result of this experiment was uniformly in favour of the ligature.

In nineteen ligature cases the average time in the hospital was twenty and a quarter days, while in nineteen selected incision cases (selected to exclude very bad ones), the average time was thirty-five days.

Broadly one may state these probable advantages of the ligature over the knife in dealing with sinuses of an ordinary character :—

1. The operation is commonly painless, and the subsequent suffering, if any, is usually very slight.
2. It is bloodless.
3. There is greater rapidity of cure.
4. The patient need not keep his bed, nor even his room, but may go into the air, driving or walking in moderation.
5. Its peculiar applicability to delicate patients, and those who have a phthisical tendency.
6. There is usually no anæsthetic required.
7. There is a minimum amount of suppuration.
8. And one may add that the ligature is often very advantageous as a supplement to the knife.

I shall make a few observations on each of these points, and relate some illustrative cases.

The operation, if it may be called so, is really painless, i.e., no more pain is inflicted than that which is caused by the passage of a probe through a sinus, and this, performed skilfully and gently, ought to give no pain, unless the sinus be inflamed. Should the fistula be an incomplete one, a slight amount of pain may be experienced in rendering it complete. The tightening of the ligature patients never flinch at or complain of.

The pain after the operation is usually very slight. Many of my patients said there was really no suffering, and they slept soundly the first night. Others were disturbed at times during the night after the operation, but afterwards were free of pain; others, delicate, excitable people, complained for some two or three days: but persons behave so differently under pain that it is very difficult to speak positively on this point. The best proof that the pain is but slight may be deduced from the fact that several of my patients have gone about their business, and not laid up more than a day; for example, a gentleman in a bank had three sinuses in his left groin, the result of suppurating buboes of long standing; one sinus passed round the thigh towards the perinæum; the length of it was  $3\frac{1}{2}$  inches. I put an elastic ligature through it one Saturday afternoon; he had pain in the night, and more or less on Sunday; but on Monday he went to his business, and continued daily to do so. The ligature cut its way out in six days, and the wound looked splendidly healthy. Emboldened by this success, on the following Saturday I put two more ligatures through the other sinuses, and again on Monday he went to his office—in fact, he only kept his house on the two Saturdays and Sundays, and in thirty-seven days he was perfectly well. A case of fistula in ano was treated by me in the same way under more unfavourable circumstances. A warehouseman, æt. 27, a delicate-looking man, had the ligature introduced on one Saturday. He went to work on Monday, and was occupied almost all day in standing and walking about, but without any further rest, except the Sundays; he was thoroughly cured in eighteen days.

My opinion is, founded on a fair number of cases, that absolute rest in bed, or confinement to the room or house, is by no means a necessity. Of course, I do not advocate much walking about or hard work, and, on theoretical as well as practical grounds, I should advise any patient who can spare the time, or whose case is severe, to take all the rest and quiet he could, in the hope of hastening the cure, and preventing any accidental interference with the healing process, and also mitigating possible pain.

The operation is almost, and on some occasions quite, a bloodless one. This, of course, is of no moment whatever in simple cases, where the amount of blood lost in the use of the knife is next to none; but when fistulous sinuses run very far up the bowel, and the parts are at

the same time, as they frequently are, both vascular and indurated, it is an advantage not to be lightly valued. I have with the elastic ligature laid open the rectum for six inches upwards in a case of stricture and ulceration, where, from the induration and vascularity of the parts, very profuse bleeding would have inevitably followed the knife, and not a teaspoonful of blood was lost. Again, in cases of hæmorrhagic tendency this method is highly useful, and it helped me out of a case which I think is quite worth shortly narrating to you.

An American gentleman was sent to me early this year by Dr. David Young, of Florence. He had long suffered from an ulcer of the rectum within the sphincter, and he had been under the care of many surgeons, American and Continental, without obtaining any permanent benefit. The usual symptoms were present in this patient, but an important feature was that for years he had frequently lost large quantities of blood from the bowel, which the ulcer did not seem quite to account for, although vascular. I made sure that the bleeding came from the rectum, and not from high up the bowel, and also that he had no hæmorrhoids; but upon this point I need not dilate. When he consulted me I found, in addition to the ulcer, a small fibrous polypoid growth close to the upper edge of the ulcer, and, as I thought this might be a source of irritation, and keep up the sore, I removed it, placing a ligature upon it; but the small pedicle cut through on drawing the ligature tight. On this accident occurring I carefully examined the part with a speculum, fearing hæmorrhage; but, as none took place, I contented myself with placing a little styptic wool in the bowel. No doubt, as soon as the slight shock caused by his trepidation passed away, and his circulation rallied, the bleeding commenced slowly, for the vessel must have been very minute. The history of the hæmorrhage was as follows: He dined, and went to bed early, and fell asleep. After two hours he awoke, feeling very faint and sick. He took some brandy and water, felt better, and again dozed off. After a time he awoke again, was faint, and felt desirous of going to the stool. This he did, and, to his great alarm, nearly filled the chamber utensil with bright red blood. He then fainted off, and was got back into bed. In my absence a neighbouring practitioner (Dr. Spurgin) was sent for, and he arrested the bleeding by means of ice. It recurred, however, the next day, and I finally stopped it with the persulphate of iron. The blood was easily retained in great quantity in this case, because the patient had a very hypertrophied and tightly contracted sphincter ani, and also a much dilated rectum, the result of the habitual use of copious enemata.

On questioning my patient, he informed me that he always bled very much on the least cut or prick, and had great difficulty in restraining the hæmorrhage. In appearance this gentleman was remarkably fair, freckled, and thin-skinned. After the removal of the polypus the ulcer still defied all treatment, and I became certain that it was absolutely necessary to do what I had at first advised—but the advice had not been accepted—viz., to divide the sphincter; but then came the question of bleeding, and I confess I was somewhat doubtful as to the result, when, in a moment, the elastic ligature presented itself to my mind as a solution of the difficulty.

Aided by my colleague, Mr. Alfred Cooper, Mr. Clover giving nitrous oxide and æther, I passed a double elastic india-rubber ligature under both sphincters, and tightly secured one ligature and left the other loose. I passed a double ligature, and left one loose, in order that the small wound made by my instrument might be thoroughly plugged up by the india-rubber. The operation was perfectly successful; really not a drop of blood was lost: the ligature cut through in nine days, and in thirty days he was cured, and returned to America perfectly well. He did not keep his bed, except the day of the operation, and did not at all complain of the pain, nor did he require any opiate.

(To be continued.)

## CASES IN PRACTICE.

Reported by JOHN W. MARTIN, M.D.,

Assistant-Surgeon Mayfield Factory Dispensary, Portlaw, &amp;c., &amp;c.

*Albuminuria—Dropsy—Weak Heart, with Enlarged Area of Cardiac Dulness—Hepatic Enlargement.*

THE following case is interesting, from the gravity of the symptoms presented and the success attending its treatment. I regret to say my notes were not as full as I would now wish, but they are sufficient to indicate clearly the appearances presented and the treatment adopted. It is one of those cases that should encourage medical men to persevere, even when all the circumstances of the case seem to point to a fatal result.

Wm. Dillon, æt. 40, car-driver, subject to every variation of weather, and accustomed to drink hard, presented himself for treatment on the 7th of August, 1873. The attack had commenced five weeks before, with pain in the region of the heart, accompanied by sense of great oppression. He was unable to account for it on any special grounds, either wetting or chill. He got a cough mixture in Waterford at an apothecary's establishment, and took some home-brewed remedies in the shape of infusion of wormwood, but received no regular advice or treatment. A fortnight before I saw him the pain in the chest subsided, the subsidence being followed by pain in the abdomen, which in turn was replaced by ascites and œdema of the lower extremities. On the day of my seeing him he walked from the car into the dispensary with great difficulty, the abdomen was greatly distended, whilst his legs were three times the size of what they were in health. The slightest exertion gave rise to severe dyspnoea; even in repose the respiration was very short, shallow, and gasping. There was a constant tendency to syncope. The lips were blue, and the facial capillaries and cervical veins congested; the whole appearances about his face were those observable during an attack of cyanosis.

The area of cardiac dulness was greatly enlarged. Heart's rhythm irregular, sounds weak, impulse scarcely to be felt; pulse 120, weak, and thready; the tongue foul; bowels confined; appetite gone. The hepatic dulness was much enlarged, the lower edge of the liver being well below the false ribs. He did not complain of any tenderness to pressure during the examination. He complained of pain and weakness in the loins over the region of the kidneys. Passes urine freely—about a pint in the day. On examination I found it highly albuminous—two-thirds the bulk, rough measurement. The recumbent position tried him greatly, increasing the dyspnoea and rendering sleep in that position impossible.

Previous to this attack the man's history was one of sound health.

The treatment consisted of hydragogue purgatives, diuretics, and tonics, as follows:—

R. Pulv. jalapæ co., ʒi. talis viij.

One to be taken at bed-time.

R. Pulv. scillæ } aa gr. i. in pill.  
Pulv. digitalis }

One to be taken three times a day.

R. Potass. iodid., ʒi.;  
Ferri citratis, ʒi.;  
Sp. chloroformi, ʒij.;  
Sp. am. aromat., ʒij.;  
Aqua ad ʒxij. M.

Two tablespoonfuls to be taken three times a day.

August 12th.—Increased secretion of urine, in which the albumen was diminished to one-half the bulk. Œdema of extremities and the ascites reduced. Treatment continued. R. Linimentum terebinthinæ, ʒvj., to be applied over the kidneys twice or thrice daily. Ordered a flannel binder to be worn round the loins.

August 20th.—Ascites and œdema of the extremities almost gone. A further reduction in the amount of albumen observed. Can lie down in bed, and sleeps well.

Appetite improved. Area of cardiac dulness diminished. Heart's action improved.

August 29th.—The jalap powders not sufficiently active. Ordered ʒij. to be taken instead of ʒi. as before.

Sept. 20th.—Has steadily improved. In consultation with my father he recommended a change from the iodide of potash mixture to one of persulfate of iron and nitrate of potash. Also gave him cod-liver oil. Continued the pills and powders.

Oct. 15th.—Suffered from occasional headaches. Bowels regular; appetite good; tongue clean. No swelling in either extremities or abdomen; free from dyspnoea; albumen only. One-twelfth the bulk of urine examined.

Oct. 29th.—Feels strong and well, and able for his work. The albumen had increased to one-sixth the bulk, but seemed to give him no inconvenience. Pain in the back and weakness quite gone. Ordered a mixture of iodide of potash, bark, cod-liver oil to be continued, attention to the bowels, and a good nourishing diet.

The patient did not again come under my care. During the past summer I have seen him plying his occupation as carman, and he looked strong and well, and stated that his health was then very good.

I present the case with no extended comments, merely as a contribution to clinical observation and treatment, and in this light I believe that the facts are worth recording.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 2, 1874.

## TYPHOID FEVER AND ITS DISSEMINATION.

DURING the past week typhoid fever has held its ground amongst us, and given considerable cause for alarm; for while it can scarcely be said to be declining, except perhaps in virulence, even at Over Darwen, it has made its appearance in other parts of the country, and seriously increased the death-rate of the metropolis. It may be said of all fresh outbreaks of fever, as has been said again and again, that the degree of sickness corresponds in every instance very closely with the degree of defective sewerage arrangement and neglected water-supply. Where house drainage is in connection with common sewers, and the foul and deadly gases accumulate and find their way back to contaminate the air and the water-supply, there sickness has been greater, and enteric fever more commonly wide-spread and virulent. Doubtless in very many country places where the dangerous cesspool system still holds its sway, and the houses are without any efficient system of sewerage, and the drains

are allowed to pass so near the water-supply that by percolation the water becomes sensibly contaminated, there sickness and typhoid fever will always be found at its maximum.

If further argument were needed in support of our statement that the water-supply is often the chief carrier of the typhoid poison, we would refer our readers to the disclosures made during the investigation of the epidemic visitation at Lewes. There typhoid fever appeared suddenly in all parts of the town, and the only one thing common to all was the use of the water supplied by a water company. The sufferers from the epidemic were almost exclusively the water-drinkers. The origin of the disease was easily traced to water-pollution, and this had arisen in a way so conclusive that it deserves to be remembered. It was owing to the supply of water having had to be supplemented during the period of drought in the summer by water taken from the Ouse, and of course believed to be pure, but which turned out to be very impure, for this river receives the town sewage throughout its course, and up to an inlet to one of the company's reservoirs. This lamentable state of things, together with a want of other sanitary precautions, most effectually disseminated the particles of the specifically diseased evacuations of those first affected by the poison. An intermittent and scanty supply of water also left the mains for hours quite empty; consequently, when the water was turned off, the foul air of closet-pans of every house was sucked into the mains, and thus the water company became quite innocently the chief agent in spreading typhoid fever through Lewes. That the water supply was the great factor in spreading the poison in this instance has been demonstrated almost beyond a doubt, for when provision was made for taking water from a better source, and constant water supply secured to the inhabitants, the epidemic at once began to decline, and doubtless will, in a very short time, be effectually stamped out. Even a worse state of things still exist at Over Darwen, and the waste of human life in that town has been due to the criminal neglect of those who, refusing to take heed in time, sacrificed numberless valuable lives which, in money value and misery to survivors, it is impossible to estimate the cost of.

The well-authenticated histories of the march of typhoid fever, and in almost a precisely similar manner, are much too numerous to dwell upon. Who can forget the very conclusive way in which the outbreak at Marylebone in August of last year led Dr. Murchison to suspect and trace it to the milk sent up to town from a particular farm. In one instance, and in one house, where four servants had been left upon board wages, two of them purchased the milk in question, while the others used condensed milk; the former suffered from typhoid fever, and the latter escaped. Many other analogous examples not less remarkable and conclusive presented themselves. Here the milk had been unsuspectingly mixed in apparently the most trifling way with foul water, and the dilution could not be detected by any of the ordinary means; but, just as in the case of yeast and other ferments, a very minute quantity of organic matter in a state of decomposition may induce changes in a very large quantity of organic fluid to which it has been added.

That *sewer-gas* or foul air is also a potent agent in the production and dissemination of typhoid no one doubts who has had experience in the treatment of the disease; but that it can be communicated by personal contact in the way described by Dr. Budd is by no means so conclusively established: nor is it likely to be taken on faith because a philosopher has attempted to thrust "the morbid agent" down our throats *volens volens*. It is indeed not a little curious to find Professor Tyndall ready in this particular instance to abandon his pet "germ theory of disease" to espouse a spontaneous generation theory of typhoid. We sympathise with a "Potential Molecule," he is indeed "receiving very unfair treatment at his hands."

The most eminent members of the profession are at issue with Dr. Budd on an essential point; and it is the opinion of the majority that there is no danger in the continuance of ordinary social intercourse with any of those persons whose families have been among the sufferers from typhoid.

One word with regard to Professor Tyndall's statement that "the very organism which is at the root of all the mischief" has been discovered. We are right in saying nothing new has been discovered, nor any other changes observed to take place in "Peyer's glands" than those we are already acquainted with. The pustular and protuberant patches are known to put on a thickened appearance, and when cut through, a yellowish-white cheesy matter exudes. Fungoid bodies, similar in their appearance to those observed by Cohn in some other allied diseases, have been often noticed, and these resemble the *monas prodigiosa* of Ehrenberg. They are small, roundish pigmentary, chromogen, bodies, and, like the micro-bacteria, are doubtless due to putrefactive changes, far more likely to be *post-mortem*, than "the peculiar typhoid matter whose presence is typical of the disease, and whose formation and elimination constitute the essence of the intestinal process."

#### THE MODE OF FIXING IRISH SANITARY SALARIES.

WHEN the Irish Local Government Board first proposed to fix the salaries of sanitary officers upon the basis of their salaries, and to draw a maximum limit above which guardians should not go, we endeavoured to show that both propositions were unjust and unpractical. It is in the knowledge of every Poor-law medical officer that the salaries awarded by guardians in different districts bear little relation to the work done by the officer, but are, on the contrary, almost wholly regulated by the considerations whether the population of the district are poor cotters or rich gentry; whether the board of guardians is composed of gentlemen or of "squireens" and petty shopkeepers; whether the rates are moderate or excessive; and whether the doctor is popular or the reverse. There are districts in Ireland where dispensary medical officers receive £80 or £90 for doing six times as much work as is required in other localities where the salary may be £120 or more, and these are the very districts in which the distances to be travelled in pursuit of sanitary work are the greatest, and in which the function of coercing a poor and ignorant population is infinitely more irksome than that to be discharged as regards the more opulent inhabitants of other localities.

The health officers of such districts receive, under the

instructions of the Local Government Board, a small proportion of a small salary for great labour, while those of "better" districts are probably awarded a considerable relative part of a much larger salary for very much less work. Consequently, if political economy is to be depended on, the sanitary work in the poorer districts, where it is most wanted, will not be done. We are glad to observe that the *London Standard* concurs in this view, and moreover enters a strong protest against the principle involved in the fixing of a maximum limit to the salaries to be voted. The *Standard* says:—

"Apart altogether from the question of sufficiency, the fixing of a maximum is an unusual and arbitrary act. It will be borne in mind that the doctor has no option in the matter. He must do the new work imposed upon him, unless he is prepared to give up his appointment, and, of course, the great majority are not so prepared, nor indeed, know where to turn for a livelihood if all threw up their employment at the same time. After taking away the refusal of an option, to follow up by fixing a maximum is thus to push to an indefensible extreme the claim of the public to override the rights of the individual. The obviously fair course would be to fix a minimum, leaving to the medical man and the local authorities to settle between themselves how much higher the salary should be. For it is certain that the local authorities nine times out of ten refuse to give the maximum."

#### VICTORIA CROSS.

UPON two combatant officers this much-coveted distinction has been recently conferred for their gallant deeds during the late Ashantee expedition. We had thought before this that the chiefs of the medical department would not have been idle, and that they would have pushed forward with zeal the claims of the profession to one of these honours. Unless this decoration is to be only obtained through intrigue and interest, it should certainly be conferred upon an officer who as fairly and honourably earned it as anyone ever did. We allude to Dr. Gore. Major Sartorius and Captain Bell have obtained the V. C., the one for having carried under cover, during a heavy fire, a Houssa sergeant, at Oboyoo, the other for encouraging his Fantee labourers to work, while much exposed, at Ordhasu. Admitting, as all will, that such acts as these were worthy of every praise, we must say that officers whose trade is war, whose duty is to lead their men on every occasion and at all risk, have no greater claim to this distinction than the military surgeon, whose art is of peace, and who, when undergoing special risks, has been invariably rewarded, especially when wounded.

Such a one-sided bestowal of honours is inexplicable to us, who do not pretend to be versed in ways military. We always thought that devotion to duty, coolness, and bravery under fire were the roads to this distinction. These were certainly displayed by the medical officer whose claims we advocate upon the two occasions when he had the misfortune to come in contact with the enemy. No one devoted himself with more zeal to the interest of the medical department, and no one, we must say, has been more ungenerously treated. In making the foregoing remarks, we do not mean to finish without saying a word for others. The members of our profession who served in Africa did their duty in a manner which called

forth the universal approbation of all lay and military writers, who have borne testimony to the unvarying kindness, skill, and pluck of the medical officers. Yet out of some 96 who served on the Gold Coast little more than five per cent. have obtained any sort of official recognition, while promotions, the Bath and coloured orders, have been showered upon others. This is much to be regretted, as heartburnings always remain where men who march side by side and undergo the same hardships are not treated each with fairness and consideration. The public service is open to all, and its honours are not intended for the favoured few, but the many. We hope it is not too late to remedy the injustice we have indicated in the foregoing remarks. Up to the present it has been all fine speeches; we now look for the practical results.

### Notes on Current Topics.

#### Leeches for the French Army.

THE *Chemist and Druggist* says that the number of leeches required for the French army hospitals exceeds 100,000 per annum. The supply for the next three years is about being contracted for, at an average price of 125 to 135 francs the thousand.

A special commission is charged with the care of receiving the leeches from the contractors, and verifying the number and quality. They must be of the kind denominated *vertes* (green), or *grises* (grey), from either France or Hungary, or of the description called *dragon*, from Algeria.

After being counted, they are placed on a horse-hair sieve to drain; the largest ones are taken one by one, and made to disgorge, as they are not accepted when they contain more than fifteen per cent. of their weight in blood.

After this operation, the leeches are weighed; a thousand should reach 1,750 grammes, while their individual weight should be, for the smallest, one and a half grammes, and for the largest, not over two grammes.

Taking as a basis of cost 130 francs the thousand, the total of the three years' contract should reach nearly 40,000 francs.

#### Medical Athletes.

Two of the finest athletes in Washington are members of the medical profession. One of them lifts 1,000 pounds with his hands, and puts up a dumb-bell of 130 pounds. The other is said to be the strongest man in Washington for his size. He lifts 400 pounds with one hand, and pends 63 pounds at arm's length on his little finger.

#### Fraudulent Musk.

A CASE of some interest to pharmacists was tried at the Court of Exchequer, at Westminster.

Mr. Jeune, who is a broker, sought to recover from Mr. Monjoseph, who is a drug merchant, the price of a caddy of musk weighing 19½ oz., and valued at £32 13s.

The evidence went to show that plaintiff offered defendant a caddy of *fine Tonquin musk*; the latter did not at once purchase, but offered it to export druggists of Liver-

pool, who replied that they could do with it if of fine quality; the defendant wrote plaintiff to this effect, and with his permission sent the caddy to his customers on approval, with a request that the pods should not be cut open or disfigured unless they were purchasers.

One of the firm made an examination of the pods, pricking with a needle in the usual way, and looking for stitches; they had, as a whole, the appearance of being genuine, and it was ultimately decided to purchase, accepting them, according to declaration, as fine Tonquin musk. About ten or eleven days after the pods were all cut open, and of the 19½ oz. only 6½ oz. were found to be musk, the remainder being earthy matter, &c. The pods were returned to defendant, who in turn offered them back to plaintiff, but he refused to take them, and brought this action to recover amount. On his behalf it was argued that it was the custom in the musk market to examine by pricking only, and not by cutting, and that the purchaser always took upon himself the responsibility of the contents, it being understood that musk was largely adulterated.

For the defence it was argued that the article was specified and declared to be something which it afterwards proved not to be; fine musk had been purchased, but had not been supplied. Dr. Symes, in his evidence, said that he looked for stitches, but so ingeniously were they sewn that he failed to detect such till after cutting them open.

The Judge, in summing up, said that in all probability the fraud had been committed in China, and it would be for the jury to say which of them was to suffer the loss. The evidence had narrowed itself into two points, and from these they should arrive at their decision. There was such a thing as buying an article from appearance without any declaration being made as to its nature; in that case as soon as the seller had handed over the article his part of the contract was complete. The plaintiff had, however, admitted having offered the contents of this caddy as fine Tonquin musk, and in so doing had contracted to supply the article named. The second point was one on which the law was very exact—viz., if the purchaser of an article keeps it for an undue length of time before he notifies to the seller that the article is not what it was declared to be at the time of purchase, then the responsibility rests with the purchaser, and he has no power to recover for any loss he may sustain.

### The Earliest Record of Auscultation.

In the *Chicago Medical Journal*, Dr. Hyde, of Chicago, gives an account of the surgical works of Lanfranc, of Milan, written about the year 1300.

An old English translation of a portion of the seventh chapter, entitled "Of the Wounde of the Heade with breakinge of Cranion," is interesting as an indirect confirmation of the idea that there is nothing new under the sun, and that the practice of auscultation and percussion was recommended 500 years before the birth of Laennec.

"When the wounde is made in the heade, with breakinge of the sculle, consider whether it be broken unto the inwarde partes or no, that is to saye, to duram matrem, whiche thou maiste knowe by divers meanes waies, partely by perseverance and partely by infallible experimentes. The signes be these: the feelinge of greates paine, vomiting teares of the eies, crokedness of the syghte, inflammation

r rowlinge of the eies. And the experimentes are these: Oake a stronge threde, double twisted, and wexe it, and let the patiente holde it stronglye in his tethe, and begin thou at the mouthe of him, and with thy nailes stretche and streigne out the threde, til thou come at the other end of the same, holding it straight a cubite lengthe from the tethe, and make a sounde upon the threde with thy nayle, and doe so often times. If the patiente may susteine the sounde without feelynge of peine, then is not the sculle broken to the dura mater, for, if it be broken, he maye in no wise susteine nor suffer the harping of the nayles upon the threde. Or else thou mayst also take and smyte his head with a smalle dry wand of wylowe, or of ye pine tre, and holde thine eare to hys head. And if the sculle be whole, it wyle make an hole sound; but if it be cutte or broken, it will make a dumme noyse, after the comparison of a broken bell."

### The Meeting of the British Medical Association in Edinburgh, 1875.

A MEETING of members of the medical profession was held on Friday, the 20th, in the College of Physicians, Sir Robert Christison in the chair, to take the preliminary steps towards receiving the British Medical Association next summer. The Chairman remarked that by many it had been thought advisable that the British Medical Association should not have been invited to Edinburgh until the New University Building and the New Infirmary had been completed; but such a strong desire had been expressed on the part of many leading members of that body to visit Edinburgh, that it could not be overcome. He (Sir R. Christison) had been elected President-elect, and he ventured to express a hope that a warm and adequate welcome would be accorded to the expected visitors.

Dr. Matthews Duncan informed the meeting that Professor Spence had consented to give the Address in Surgery, Dr. Warburton Begbie that in Medicine, and Professor Rutherford that in Physiology.

### The Conjoint Examination Scheme for England.

THE *British Medical Journal* is "glad to learn that the Conjoint Committee of Reference are prepared to adopt a scheme which will aid in the solution of the difficulties which have been experienced by the College of Surgeons in reconciling the condition of its charter to the proposed arrangements for appointing examiners under the Conjoint Scheme. These negotiations have now lasted five years; they were commenced by the Colleges of Surgeons and Physicians, London, and the Universities. The Apothecaries' Society have made great sacrifices to assist in attaining a simplification of the system of examinations for an uniform and complete minor qualification to practise. It would be unjust to the London College of Surgeons to doubt their loyalty in a matter of so great national importance, and in which they have long been deeply committed to a measure which the Government, the Medical Council, and the whole profession in England agree to regard as one of pure utility. There has already been too much delay in this matter, and only the London College of Surgeons now stops the way."

On the 10th of December a dinner is to be given to Dr. Hardwicke, the new Middlesex coroner. Dr. Richardson, F.R.S., is to take the chair.

**Small-pox at Rugby.**

By telegraph we learn that small-pox has broken out in Rugby in a most alarming and sudden manner. The authorities held a special meeting on Saturday, and decided to build a hospital for the reception of patients forthwith. With commendable zeal, the work was at once undertaken, and a large body of workmen were engaged until late on Saturday night, and during the greater part of Sunday, in the erection of a temporary hospital.

**Acclimatization of Ipecacuanha in India.**

THE *Pharmaceutical Journal* notes that in the last report of Dr. King, Superintendent of the Calcutta Botanic Gardens, he states that the propagation of the ipecacuanha plant by root and leaf cuttings has been so successful that there is at present a stock of 63,000 living plants; whereas four years since there were at the Cinchona Gardens but twelve cuttings, of which seven were afterwards accidentally destroyed.

**Haydn's "Dictionary of Domestic Medicine."**

EVERYONE is acquainted with Haydn's "Dictionary of Dates," which has so long maintained its place as an indispensable book of reference. Messrs. Moxon have now issued a companion volume on domestic medicine, edited by the late Dr. Lankester, F.R.S. We by no means favour the domestic practice of physic; but there are cases in which a rational guide is of great value. Captains of ships on which no surgeon is carried, missionaries in far off settlements, and other educated persons in places where professional advice is unattainable, are glad to possess books of this kind. For all these we can recommend this dictionary. Its alphabetical arrangement makes it easy to refer to any point, and it contains sound advice on all questions of hygiene. It is therefore a great deal more than a mere guide to the medicine-chest. This might have been expected in a work to which Dr. Lankester lent his name; and he modestly tells us that he obtained the assistance of his professional friends on those points on which he felt to need such aid. We have tested several of the more difficult articles, and found them very good. We congratulate the publishers on having produced the best work of the kind.

**Diagnosis of Death.**

DR. MONTEVERDI DE CREMONI has proposed a simple, easy, and certain method of seeing whether a person is really dead. He injects a drop or two of ammonia beneath the skin. If the person be dead no effect, or next to none, is produced; but if the person be alive, a red colour appears at the point of the injection. He has published a pamphlet on the subject, illustrated with six plates, and the plan, simple as it is, seems likely to be useful, to prevent the possibility of burying alive.

By the will of the late John Paine, Esq., of Patcham Place, near Brighton, the Sussex County Hospital, Brighton, receives £5,000; the Brighton and Hove Dispensary, £5,000; and the Cancer Hospital, Brompton, £1,000. The testator also bequeaths about £15,000 to charities in connection with the Church of England.

**Dignified!**

THE Registrar-General has withdrawn his name from the list of honorary members of the Society of Medical Officers of Health because its President, Dr. Letheby, criticised so severely his statistics in the address of which we recently published a full abstract. We wonder if Major Graham imagines that he has demolished the Society, or furnished a reply to Dr. Letheby's strictures!

DEAN STANLEY has been unanimously elected Lord Rector of the University of St. Andrews.

THE death is announced of Surgeon-General Bent, M.D., who was stationed at Aldershot.

A GREAT number of inquests are reported in the daily papers from accidents that happened during the late fog.

BIRMINGHAM has obtained permission to make some new sewers, but is hardly even yet out of Chancery.

MR. HAVILAND has illustrated a recent report of his with two maps, to show the distribution of fever; this is an excellent plan.

THE Vestry of St. James's has decided to combine the offices of Public Analyst and Medical Officer of Health, and the decision is a wise one.

DR. PARKES has given notice of a motion to the effect that it is desirable to institute degrees in State Medicine at the University of London.

ST. JOHN'S HOSPITAL has decided not to accept any portion of the Hospital Saturday Fund for the present year.

ST. PETERSBURG is to be drained on Captain Liernur's system, at a cost which is estimated at nearly four millions. This system has been successful in Holland.

DR. LETHEBY has recently published (Statham and Co.) a useful paper on the right use of disinfectants, which was read by him a year ago at the Association of Medical Officers of Health.

ACCORDING to the report of the medical officer of health, Brighton is now in a very healthy condition. We are also informed by our correspondent that the weather lately has been very fine.

DR. RUSSELL REYNOLDS has published (Churchill) the Address in Medicine delivered by him at Norwich; it will well repay perusal. Its object is to show the influence which modern scientific thought and method exert on daily practice, and he expresses his belief in the value of subjective symptoms in most forcible terms. He treats of a belief in life, in man, in individuality, and in the speciality of disease. We have read the Address with much pleasure.

At Blackburn last week there were nine deaths from typhoid fever. The number of cases under treatment is about 400.

THE inhabitants of Hampstead are making great efforts to prevent the establishment of a fever hospital in their healthful suburb. It is not surprising they should be alarmed at the prospect.

At a meeting of the Stourbridge guardians on Friday last the governor of the house reported that two children had died from the effects of a dose of diarrhoea medicine administered by a nurse without orders.

THE inspector of burial grounds, Mr. P. A. Holland, has held an inquiry into some irregularities alleged to have occurred at Liverpool somewhat like those lately discovered at Tooting.

THE Duke of Edinburgh will preside at a meeting in Willis's Rooms, on Monday next, for the purpose of providing new buildings to meet the wants of the University of Edinburgh. A sum of £60,000 has already been subscribed, and a further sum of £40,000 is required.

DR. F. J. MOUAT has been appointed to fill the vacancy caused by the death of Dr. Edward Smith in the staff of the English Local Government Board. His duties will be those of Medical Inspector for the Provincial Poor-law Unions.

DR. THORNE THORNE has made a report on the outbreak of typhoid fever at Lewes, in Sussex. It seems to have been due to some children having in play fixed open a valve which prevented the tidal stream from passing into the reservoirs, a warning that such valves should be placed out of the reach of mischievous little fingers.

A GENERAL meeting of the Society of Public Analysts was held at the Cannon Street Hotel yesterday, at four o'clock p.m., to consider the definition of adulteration, and to deliberate upon the steps which it is desirable to take to further the amendment and consolidation of the Adulteration Acts.

ON Saturday an action was brought against Dr. Donald Macrae, who is in practice at Hanwell, by a Mrs. Taylor, wife of a draper, for an alleged assault. There was the charge, and the defendant's denial, which was confirmed by his witness. That there was the usual amount of false swearing on one side or the other is a matter of course; in which quarter it lay will have to be determined by a jury, the case having been sent for trial at the Sessions.

THE first meeting of the Surgical Society of Ireland, which was adjourned from last Friday, in consequence of the death of the late Dr. Hargrave, will take place on Friday evening next, in the Albert Hall, Royal College of Surgeons. The President of the College, Mr. Tufnell, will deliver an Inaugural Address, and the following communications are set down for reading: Mr. Mapother, 'On Cancer of the Male Breast'; Mr. H. G. Croly, "On

a Case of Tetanus;" Mr. Corley, "On a Case of Parotid Tumour."

THE Local Government Board have snubbed the Waterford Board of Guardians. A few days ago the Waterford Board passed a resolution to give the rural dispensary medical officers the munificent salary of £10 a year, or 6½d. per day, for all their labour and trouble under the Public Health Act, of which, by Act of Parliament, they are the chief officers. This resolution was sent to the Local Government Board in due course; but on Wednesday there was a reply from that body, which anyone might expect, that they could not sanction such inadequate salaries. Before the silly resolution was passed a juster and more reasonable salary was proposed—£20 a year—which the Local Government Board would be more likely to sanction; but the guardians, in their wisdom, threw this resolution overboard. On Wednesday the guardians received another letter from the Local Government Board, directing them again to reconsider the matter, and increase the salaries; but although a motion to that effect was proposed, it was defeated. The Local Government Board have distinctly stated their intention of fixing the salaries at the maximum.

## Transactions of Societies.

### MEDICAL SOCIETY OF LONDON.

MONDAY, NOV. 16TH, 1874.

DR. BROADBENT, Vice-President, in the Chair.

DR. THOROWGOOD read a paper on

#### GASTRIC VERTIGO.

Notes of two cases, as illustrating the following remarks were given. *Case 1* was that of a gentleman, æt. 45, regular and careful in his habits of life, and by no means addicted to stimulants. This patient was troubled by frequent attacks of giddiness and vertigo; at times he would fall in a faint, with transient loss of consciousness. Frequent and careful examination failed to detect any organic lesion. The face was pale; pulse slow and regular. A course of Vichy water disagreed notably in this case, and various tonics, such as iron, quinine, &c., failed to exercise any curative action over the syncopal attacks. Wine was recommended at meals; and brandy and water whenever the attack of vertigo threatened. This treatment was regularly carried out, and the patient became decidedly worse under it. As a part of complete change in the plan, alcohol was entirely abandoned, and by degrees the attacks of vertigo and syncope ceased. *Case 2.*—A lady, æt. 35, had frequent attacks of faintness in the morning on awaking, and at other times no organic lesion could be discovered. The use of alcohol always gave temporary relief; but by degrees the attacks became so frequent that the patient was alarmed at the constant necessity for the stimulant remedy. Iron, quinine, and a variety of tonics did very little good here, but a resolute adherence to claret and water to the exclusion of other alcohols, as a drink had an obviously beneficial effect. Dr. Thorowgood believed local cerebral anemia to be the pathological condition in these cases. In certain parts of the brain the arteries were spasmodically contracted, while the venous ventricles were full and engorged. It might be said that a bloodless brain was commonly assumed as the condition in a person given to fainting, and that the proper treatment was to stimulate the heart, and so send more blood to the brain. Against this idea it was urged that practical experience showed that stimulating the heart, while it relieved for a time, tended in the end to perpetuate the original malady. The

true pathology might probably be found in the observations of Dr. Fothergill on cerebral anæmia in the West Riding Asylum Reports, wherein were given the experiments of Cyon and Alladoff, showing the inhibitory influence of certain nerves over the vessels of the brain in causing their contraction, and limited anæmia as a result. These inhibitory nerves had been traced from the liver up the vertebral arteries to the brain. Irritation of stomach and liver thus propagated to the brain caused spasmodic contraction of arteries, and local cerebral anæmia, with all its recognised consequences. Alcohol, by tending to irritate the liver, would therefore be injurious. The cure of these cases, even when very inveterate, might confidently be looked for, in, first of all things, careful regulation of the supply of alcohol, coupled with moderation as to diet, regular exercise, and so forth. As medicines, columba, with bicarbonate of soda, and tincture of ginger would be found very useful, the alkali tending to correct any acidity about the juices of the stomach induced by alcohol taken when the stomach was empty. Such acrid secretion would cause feeling of faintness, and a not unnatural craving for a little brandy. The ginger in a small dose would act as a stimulant mildly, and so relieve the craving for brandy or sherry. Subsequently the use of iron in combination with sulphate of magnesia or soda was to be recommended as a tonic laxative. By this simple method, carried out with decision, it was not too much to say that cases that had been called incipient epilepsy, or instances of very obscure nervous disease, might readily be cured.

Dr. FOTHERGILL was flattered at the allusion made to his essay in the West Riding Reports, and remarked that a clear connection had been made out between the stomach and the larger nerve centres through branches of the sympathetic, the occipital lobes being the portions of the brain implicated. Anæmia of the brain was not always accompanied by depression of spirits, and in these cases the state of the vessels of the brain was more probably that of spasm than of anything else. He could not help alluding to Dr. Ferrier's experiments on monkeys, where irritation of the occipital lobes produced marked symptoms of melancholia.

Dr. THEODORE WILLIAMS had seen many cases similar to those narrated by Dr. Thorowgood, and while agreeing with his treatment, he could not altogether endorse his pathology. Most of these cases occurred among people with tippling habits, whose practice it was to take stimulants between meals whenever they felt what they call "low." The result was bad in two ways—(1) the alcohol introduced into the stomach caused a large secretion of gastric juice, which, having no food to act on, irritated the mucous membrane, and gave rise to flatulence, distending the stomach, and thereby disordering the heart's movements—hence palpitation and irregular supply of blood to the brain, with its accompanying symptoms; (2) the waste of gastric juice prevented a proper amount being forthcoming at meals—the food was only partially digested and escaped assimilation—hence starvation of the blood and consequent anæmic symptoms. The treatment most successful, therefore, in these cases, was a careful combination of food with stimulants, and a reduction of the latter as much as possible.

Dr. ROUTH agreed with the author as to the common occurrence of these cases among women, often accompanied by leucorrhœa. Chronic alcoholism he noticed chiefly among matrons, and he treated it by two methods: the hankering after stimulants he satisfied by a harmless one, in the form of a-safetida, or valerian, or else he gave raw beef juice, prepared by rubbing beef through a sieve, and flavouring it with a little celery. Three claret glasses a day were given of this juice, and it allayed the hankering for spirits without causing tapeworm. He cited a remarkable instance of recovery from its use.

Dr. BROADBENT was not sure these cases came under the head of vertigo at all. He noticed vertigo to exist in two opposite states of the vascular system—(1) with the arteries quite relaxed, skin moist, and the pulse soft; (2) with the arteries tight, and the pulse strong and firm. He endorsed the author's treatment.

Dr. THOROWGOOD, replying, said that all his cases were not those of habitual tipplers, and that he had used the term vertigo for want of a better.

Dr. LEONARD SEDGWICK read the records of

#### A CASE OF RUPTURE OF MUSCLES AND PULMONARY EXTRAVASATION.

After a railway collision a gentleman, æt. 66, who was much shaken, and who was cut over the eyebrow, was seized on the third day after with a severe sickening pain in the left

calf, where there was a tender depression and some ecchymosis, as well as a yellow branched line in the site of the inner saphena vein. On the twelfth day he had an isolated patch of tinea outside the lower angle of the scapula, where the breathing was turbulent, the percussion dull, and over which there was some friction sound. The pleuritic pain was relieved by leeches; but a few hours after a sudden pain struck him in the lower part of the right chest, like that in the calf, and there was over the base, and a little below the lower ribs, a harsh grating noise, audible at a distance, produced apparently by irregular and severe contraction of dorsal muscles, coincident with each respiratory murmur, and caused, as the author believed, by rupture of muscular fibre. At a later period of the case the right calf of the leg was affected in the same way as the left had been. The agonising pain in the back was speedily relieved by injection of morphia, and simultaneously the harsh bruit ceased.

Dr. SEDGWICK was of opinion that the pulmonary extravasation was shown by the expectoration of blood clot, and was caused by the arrest in the lung of a small piece of clot which had been broken off from that in the leg.

After some remarks by Drs. CROMBIE and BROADBENT, Dr. T. S. DOWSE brought forward the clinical history and pathological appearances of a case which to him seemed obscure both in its etiology and diagnosis. The patient was 31 years old. The special features were allied to a cerebro-spinal meningitis, uræmic poisoning, typhoid poisoning, or to some other morbid factor. But the signs and symptoms throughout the course of the diseased state were not absolutely relevant to either of the foregoing conditions. There was more or less somnolence, with twitching of bilateral groups of facial muscles, pseudo-paraplegia of the lower extremities, with cutaneous anæsthesia and muscular hyperæsthesia. There was persistent diarrhœa, with involuntary discharges; no vomiting; the most marked feature was the moist, clean, healthy-looking tongue, which remained until within a couple of days of her death. The ratio of pulse, respiration and temperature was fully detailed. At the post-mortem there was diffuse amyloid change over the cerebral hemispheres, with an increase of fluid in the sac. The pia mater was hyper-vascular. These conditions existed also in the membranes of the spinal cord, which seemed softened in the dorso-lumbar region. The lungs were healthy. There were recent adhesions between the layers of the pericardium, and attached to the anterior cusp of the mitral valve was an organised mass of laminated fibrin, the size of a small walnut; the other cusp was quite healthy. The cavities of the heart were otherwise free from blood, or ante-mortem polypoid clot. On account of this growth there could not have been complete closure of the valves, which gave rise during life to a pure and definite diastolic murmur. This Dr. Dowse thought exceptional, and differing altogether from the pre-systolic grind of a stenosed orifice on the one hand and the systolic regurgitant bruit on the other.

Dr. BROADBENT thought it was an instance of ulcerative endocarditis. Slight ulceration of a portion of the mitral valve had occurred, in which a clot of blood formed which was fibrinous. Minute portions of this had become detached and were carried into the capillaries of various organs, causing small embolisms, and giving rise to pain in the spleen, the symptoms of paralysis, &c. In these cases the embolisms were very minute, and not visible to the naked eye, but could be detected under the microscope. He remembered a case where large thrombi were found in both radial and femoral arteries. As a rule, cases of capillary embolism were accompanied by minute petechiæ of skin.

Dr. THEODORE WILLIAMS had some doubt about the blood-poisoning in this case, and, while concurring with Dr. Broadbent that it was a case of ulcerative endocarditis, drew attention to the fact that no emboli were found in the liver or lungs, the most common seat of this occurrence.

Dr. DOWSE, replying, said no embolisms were found in the brain or spinal cord.

## Literature.

### THE PROTOPLASMIC THEORY OF LIFE. (a)

The author of the work before us is well known to the

(a) "The Protoplasmic Theory of Life." By John Drysdale, M.D. London: Baillière, Tindall, & Cox. 1874. 8vo, pp. 289.

scientific world by his works on the microscopic investigation of the interesting point of spontaneous generation, and on life and the equivalence of force.

The subject of this work was the theme of an inaugural address to the Microscopical Society of Liverpool, delivered by him as President. It is divided into twelve chapters. Chapter i. treats of Dr. Fletcher (Edinburgh) theory of one only living matter. In 1835 Dr. Fletcher laid down that "if vitality do not reside in a separate principle, but depend on the mode of combination of the elements of the organic parts themselves, there can be no central vital influence communicable to the parts and dominating them, for the vitality of each must be inherent in itself, and, as a property of the material compound, cannot be transferred to the smallest distance; each part, organ, and even cell, therefore, possesses a quasi-independent life, and they are all bound together to form an individual merely by the ties of a central nervous system and common circulation, or some similar means." . . . "That the property of vitality does not reside equally in the various organic structures requiring such different physical properties, but is restricted solely to an universally diffused, pulpy, structureless matter, similar to that of the ganglionic nerves and to the grey matter of the cerebro-spinal nervous system."

The elements of this substance are in a state of combination not to be called chemical at all, in the ordinary sense, but one which is utterly *sui generis*. In fact, no albumen, fibrin, protein, or fats exist at all in living matter, but that the sum of the elements of these is united into a compound for which we have no chemical name, and it is only at the moment of death that these chemical compounds with which we are familiar take their origin.

The physical and chemical description of this one true and only living matter is that of a pulpy, translucent, homogeneous matter, yielding after death fibrin. Thus, all that is properly called structure, and gives beauty, form, and fitness for purpose to animals and plants is dead, and composed of merely chemically combined elements, just as we find it after death.

In chapter ii. the author treats of the cell theory before 1860. In 1838 the microscope was sufficiently perfected to give a solid basis for the observation of facts. Schleiden, the founder of the cell theory, defines the vegetable cell as "the elementary organ which constitutes the sole essential form element of all plants, and without which a plant cannot exist, and as consisting, when fully developed, of a cell-wall composed of cellulose lined with a semi-fluid, nitrogenous coating." Schwann observed that the whole organism subsists only by means of the reciprocal action of the single elementary parts. The cause of nutrition and growth resides, not in the organism as a whole, but in the separate elementary parts, the cells.

The author remarks on this theory, that in all modifications of the cell theory, even those which allow for the occasional absence of the cell-wall, that part when present is believed to take an active part in the strictly vital process of transformation into tissue; but the cell-wall possesses a certain rigidity, and shades off into the intercellular substances, which offer an infinite variety of composition, many of them being non-nitrogenous, a composition incompatible with life. For these reasons the attribute of vitality cannot reside in anything of the nature of a cell-wall and of a cell taken as a whole.

In chapter iii. the author speaks of the protoplasmic theory before 1860. It appears from the analysis here given that the threefold form of the cell was soon given up, and that, although the dual form of the nucleated cell, without cell-wall, nominally holds its place, still, life has been shown to exist in the simple form of a structureless, viscid, semi-fluid matter common to both animals and plants.

In chapter iv. Dr. Drysdale treats of Beale's protoplasmic theory. In 1861 Dr. Lionel Beale, who had devoted himself with unwearied zeal to microscopical research on the animal tissues, delivered some lectures before the Royal College of Physicians. The cardinal point in

Beale's theory is that, from the earliest visible speck of germ up to the last moment of life, in every living thing, the attribute of life is restricted to one anatomical element alone, and this homogeneous and structureless; while all the rest of the infinite variety of structure, solid and fluid, which make up living beings, is merely passive and lifeless formed matter. This is called by Beale *bioplasm*, and is described as "always transparent and colourless and structureless" at all points of its existence, whether in an oak or a vertebrate animal.

The name *bioplasm*, or *protoplasm*, is thus given to the ideal living matter of all plants and animals.

According to Beale, "of the matter which constitutes the bodies of man and the animals in the fully-formed condition, probably more than four-fifths are in the formed and non-living state. All this was, however, living at an earlier period of existence." On *bioplasm* depends all growth, multiplication, conversion, and life. The difference between it and *pabulum* is absolute. The ultimate particles of matter pass from the lifeless into the living state, and from this into the dead state, suddenly. Nothing is known of the chemical composition of *bioplasm*, says Beale. When a mass of *bioplasm* dies it is resolved into fibrin, albumen, fatty matters, and salts.

It seems that *bioplasm* has the property of alone becoming tinted by a solution of carmine. *Bioplasm* is constantly present in all living parts of the same animal; even in the vitreous humour numerous *bioplasts* exist. It is predominant in young, growing parts, and the activity of growth of a part may be judged of by the number of *bioplasts* it contains. Thus, Harvey said, *Omne vivum ex ovo*; Edwards, *Omne vivum e vivo*; Virchow, *Omnis cellula e cellula*; and Beale says, *Nihil vivum nisi protoplasma*.

Chapter v. contains a continuation of the subject, and refers to objections to Beale's theory. Dr. Wyville Thompson thinks it more probable that *protoplasm* has always the same composition, and that it acts by catalysis.

Beale speaks thus of the blood: "I believe that the *bioplasts* of the capillary vessels play a far more important part in the changes in the body than has hitherto been supposed. The *bioplasts* of the capillaries in the lungs are the agents by which certain animal matters are separated from the blood and transferred to the air in the pulmonary air-cells."

Chapter vi. treats of the cell and *protoplasm* theory since 1860. The author says: "While we find *protoplasm* generally admitted to be the simplest form of living matter, and credited as the agent of much vital action, and ever as the germinal substance from which all tissues proceed, yet it is far otherwise with the doctrine that it is the sole living matter in organisms with a complicated structure. Indeed, in this Beale stands alone among living physiologists, just as Fletcher did nearly forty years ago. The doctrine has hardly even been properly criticised as yet; in fact, its significance has not been fully grasped, and people seem to be satisfied without further thought that a system which makes four-fifths of a man, including the muscles and nerve cords, to be nothing but dead matter, must be an error of some kind; and this, with the erroneous idea that it rests on the carmine staining process and requires the revival of the vital principle, further indisposes them to give the theory the attention it merits."

In chapter vii. the author gives a commentary on Beale's nerve theory, and in chapter viii. his muscle theory. In page 167 he says: "These facts form an insurmountable argument against Dr. Beale's hypothesis that electricity is the nerve force, and exactly his theory of muscular action adds insuperable force to the argument against the electric theory, for, although it might not have mattered so much sending the force of a mere stimulus, of which so small a quantity is needed, through a bad conductor, how can we reconcile it with the economy of nature, that a force which has to do the whole work of the muscles should be sent through a conductor which offers three million times the resistance of mercury, and still more than that of silver or copper. We are, I think, compelled

to conclude that the force must be a distinct force, not like light, or sound, but a current force analogous to electricity, galvanism, and magnetism, but distinct from these."

In chapter ix. Dr. Drysdale speaks of the nature of life. Dr. Fletcher, it seems, holds vitality to be synonymous with irritability, or the faculty of undergoing, upon the application of a stimulus, any change not strictly chemical or mechanical. Life is, therefore, not an entity, nor a force, but an action, and, moreover, that action alone which is involved in the consumption and regeneration from pabulum of a material compound entirely *sui generis* called irritable matter, or protoplasm, under certain conditions and stimuli. Living matter has long intervals of a resting stage, or even a state of suspended animation. In seeds and germs life seems dormant for long periods, and all change is reduced to a minimum. "Dr. Beale still clings to his theory of a hyperphysical cause or vital principle which can initiate vital movements. Formerly he did not hesitate to say they were directly the offspring of a hyperphysical vital power, but having stated that he did not assert the creation of force by living matter, he is now obliged to deal with the subject in a more guarded manner, and it is not easy to say what he does mean in his third edition of 'Protoplasm,' where he says that the antecedent that occurred just before the vital movement cannot be proved to be phenomenal."

"But the strongest proof of the non-existence of spontaneity is given by Beale's absolute denial of the existence of unipolar nerve cells. There are always two poles at least, and often many more. If the nerve-cell could start into activity spontaneously, and if any purpose were to be served thereby, one cord would be enough to convey the evolved energy, as far as we know, for we do not know that the second is necessary for any electrical reason, i.e., to complete the circuit. The second is no doubt an afferent, or commissural fibre, whereby the stimulus is conveyed to the nerve-cell for the purpose of exciting it to activity at the right time, and so there can be in health no other mode of activity possible, for that would frustrate the very purpose of the organ. A portion of the grey matter upon the surface of convolution not larger than the head of a small pin will contain portions of many thousands of nerve fibres, the distal ramifications of which may be in distant and different parts of the body. The bioplasts referred to are directly concerned in mental action. Movement affecting the matter of many thousands of these minute bioplasts, probably at the same moment, is required for the initiation of the simplest idea."

Chapter x. treats of the connection of force with life and mind. Force, says the author, is not an object capable of existing *per se*, but is only the motion of matter and æther, or the pressures antecedent to that motion. It is but an affection of matter. "Force," says Mayer, "is that which is expended in the production of motion, and what is expended is, as cause of the effect, equal to the motion produced." The discovery of the mechanical equivalent of heat has given the death-blow to the notion of all inherent powers of attraction and repulsion as properties of matter, as well as all action at a distance, which were till lately generally held, in spite of the strong objections of Newton himself. Matter without weight is not only conceivable, but it is easy to calculate the position in space when it can have no appreciable weight. Matter also may be conceived, according to the author, as existing without force, although chaos would result.

"When Professor Tait applies the term *pernicious nonsense of the materialist* to the deduction that volition and consciousness depend on modes of being of matter, he either commits the mistake exposed by Fletcher, that because inorganic compounds of matter do not show life or mind, therefore no other mode of combination, such as protoplasm, can, or falls into the common error of confounding the immortal soul granted to man alone with the life and mind of animals."

In chapter xi. Dr. Drysdale treats of albumen and the physical basis of life. "Protoplasm," says Huxley, "simple or nucleated, is the formal basis of life; it is the clay of

the potter, which, bake it, paint it as he will, remains clay, separated by artifice, and not by nature, from the commonest brick or sun-dried clod." He then speaks in favourable terms of the theory of Darwin and Herbert Spencer, and gives his own experiments, which oppose the views started by Bastian.

Chapter xii. treats of the existence of a God and a future state, and the author, we may add, boldly defends the doctrine that a revelation has been given to man concerning his immortality.

We cannot quit Dr. Drysdale's work without the highest commendations of the honesty, deep thought, and research exhibited in almost every page. It is the result of a man's life of thought. May it be widely read and pondered over.

### ANNUAL REPORT OF THE SUPERVISING SURGEON OF THE MARINE HOSPITAL SERVICE OF THE UNITED STATES FOR THE FISCAL YEAR 1873. (a)

THE second annual Report, for such it is, demonstrates the judicious efforts made by the United States to care for and encourage seamen.

For some years the Great Western Republic has evidenced sound wisdom in its advancement of sanitary medicine, and in the recognition of the value of the services of the medical profession, as the legitimate machinery for furthering the policy of protecting the health and lives of its citizens.

The quarantine system, being slowly, but surely revived in England on a scientific basis, and one not calculated to interfere with legitimate commerce as seen in the ports of London and Liverpool, has been in force for some time in the chief ports of the United States.

The Marine Hospital Service is made to hinge on to the Quarantine Service, so to speak.

According to the Report, "The quarantine of the port of New York is the most extensive and elaborate, as it is at present unquestionably the best administered and most efficient system in the world; the vessels of all nations through the harbour, bringing from all climes the most diverse cargoes and crews; the small-pox, typhus, and cholera, of an immense immigrant service, and the fevers of the tropics, continually threaten, and demand an unrelenting vigilance. And yet this vigilance is exercised, and the health of the port is perfectly protected, in entire harmony with the regulations necessary to ensure the care and relief promised by the Government to the sick and disabled seamen."

The vast importance to a great commercial country such as England is, and as America is endeavouring to become, of efficient seamen, is seen by the recommendation given by Dr. Woodworth for the adoption of a compulsory medical inspection of seamen before shipping.

He aptly remarks that such a step would eliminate "a class of patients who alternate between the hospital and the fore-castle with a decided preponderance towards the former." The Report is well worth reading, and furnishes an account of the sufferings of sailors, and the consequent danger to passengers, ships, and cargoes by the ill-treatment of sailors permitted in the States, and perpetrated often upon sick and defenceless seamen by the vile class of boarding-house keepers that through the parts of the American towns resorted to by seamen.

Whilst just condemnation is pronounced upon this class, representatives of which are to be found also in the ports of the United Kingdom, very serious charges are also made against the working of the recent law, whereby a class called shipping commissioners and deputy shipping commissioners are appointed.

(a) "Annual Report of the Supervising Surgeon of the Marine Hospital Service of the United States for the Fiscal Year 1873." Jno. M. Woodworth, M.D. Washington Government Printing Office, 1873.

Indeed, with the evident desire to benefit and act well by her seameh, the United States Government is shown not to have failed to protect her mercantile marine service in a manner worthy of a great nation. Abuses will probably be in time much lessened or removed.

The Report is creditably got up, and contains drawings, plans, &c.

## Obituary.

### WILLIAM HARGRAVE.

THE death of Dr. Hargrave, which occurred last week, has removed from the professional brotherhood in Ireland one of its best known members, and one whose name and works have been associated with it for nearly half a century.

William Hargrave was the fifth son of Abraham Hargrave, Esq., architect. Born in the city of Cork, in 1797, he was placed at an early age at Mr. Adair's School in Fermoy. From this seminary he entered the University of Dublin as a Fellow Commoner under the Rev. Daniel Mooney, when his "chum" happened to be Jones Quin, afterwards the distinguished Professor in the London University, with whom and the late Chief Baron Pigot, who was likewise his contemporary, he cultivated a friendship and intimacy which continued uninterrupted through after-life. Previous to graduating, Dr. Hargrave selected the surgical profession, and was apprenticed to the late Sir Philip Crampton, of whose high professional reputation our country might well be proud. Having completed the period of his apprenticeship at the Old Meath Hospital under Sir Philip Crampton, he obtained his licence at the College of Surgeons, and subsequently repaired to Edinburgh, where he availed himself of the advantages of that celebrated school of medicine. On his return to Dublin he took out his degree of Bachelor of Medicine in Trinity College. Thus qualified, he visited Paris, where he studied under Dupuytren and Laennec. Subsequently he visited Germany, Switzerland, Italy, and Greece, and returned to Dublin after an absence of two years. Then it was he entered on his professional career with a degree of energy and zeal seldom surpassed. At the rear of his house—134 Stephen's Green—he fitted up an anatomical theatre, where he was surrounded by a large class of students anxious to avail themselves of his instruction. Probably in this step he was influenced by the example of his distinguished master, Sir Philip Crampton, who in early life used to instruct his pupils in a stable loft at the rear of his house in Dawson Street. It may be interesting to record here that amongst Dr. Hargrave's first pupils was Charles Lever, who was then studying the medical profession. The high estimation in which the lectures delivered by Dr. Hargrave were then held is proved by the fact of their subsequent recognition by the licensing bodies. After the lapse of a few years he, in conjunction with Sir Dominic Corrigan, the late Mr. Auchinleck, Drs. Churchill and Hunt, founded a medical school in Digges Street, from which he withdrew on his appointment to the Chair of Anatomy at the College of Surgeons, which he subsequently relinquished for the Professorship of Surgery, rendered vacant by the retirement of the late Dr. Samuel Wilmot. About the period of his appointment to the Chair of Practical Anatomy Dr. Hargrave became one of the surgeons to Baggot Street Hospital, where, until his health began to fail, he devoted all his skill and characteristic energy to the relief of the poor sufferers committed to his charge.

Professor Hargrave's surgical work within his hospital and his practice was extensive, and sterling in its character, and he has committed to the press several records of unique and valuable surgical and anatomical experiences. His largest work was his monograph on operative surgery, published in 1831, and it was followed in later years by a remarkably original paper on the uses of Meckel's ganglion, which he published in the *Edinburgh Medical Journal*. He also enriched the literature of

surgery with a communication on the demonstration of arteries by the transverse section of muscles—a paper on a new form of dislocation of the head of the humerus. One of his most creditable surgical feats was the operation of ligaturing the left common iliac artery, the second occasion, and the first successful case, in which that proceeding was followed in Ireland. This remarkable operation was performed by him in the City of Dublin Hospital, in 1865, and, the patient having afterwards died of gangrene of the foot, the specimen is now in the Museum of the Royal College of Surgeons in Ireland, and was recently exhibited by Mr. Holmes in his lectures on aneurism before the London College.

"It has on various occasions been," says a biographer in the *Dublin Evening Mail*, "the writer's lot to witness the anxious solicitude often displayed by Dr. Hargrave as an hospital surgeon, and it is enough to say that it was only consistent with his naturally kind and benevolent disposition. The excellent hospital with which he was so long connected seemed to have constituted the last link of his connection with professional life. As consultant he was to the last anxious about its suffering inmates. He has now retired from this busy scene of life, honoured with all the distinctions his profession could bestow, a lasting memorial to his memory: 'Non omnis moriar, multaque pars mei vitabit libitinaum.'"

Dr. Hargrave's medico-political life was directly and intimately connected with the Royal College of Surgeons, in which he served as President, for very many years as Councillor, and afterwards as its representative on the General Medical Council. On many occasions he was selected to speak on behalf of the College when its interests were represented by deputations in London, and his relation to the College in this capacity terminated only with the physical disabilities of advanced age. His memory will long be respected in his profession as that of a man unfailingly truthful—loyal to his College, and honest in his views and speech, and indefatigably zealous in the pursuit of every movement which promised to benefit either his professional brother or the College which he served.

### THE LATE SIR J. R. MARTIN, C.B.

A VERY well-known and conspicuous figure in London medical society has passed away in Sir Ranald Martin, whose death will be deeply regretted both in England and India, in both countries of which he was greatly esteemed for his skill and his personal qualities. His death may be called unexpected, inasmuch as only a week or two ago when he resigned his appointment at the India Office, it was stated in several of the papers that he still enjoyed good health, and only sought the repose to which he was so well entitled, after more than half a century of honourable service. In 1817 he became a medical officer on the Bengal Establishment; in 1821, in the Burmese war, he had charge of the body guard of the Governor-General; and in various capacities he continued to serve the honourable East India Company up to 1840, when he was compelled by the state of his health to leave India. He then retired from the service of the Company, and in due course began consulting practice in London, where he continued up to the time of his death to be the chief authority on tropical diseases. During his Indian career he practised in Calcutta, and his name has always been revered at the General Hospital of that city. In 1843 he was elected a Fellow of the Royal College of Surgeons of England, and two years later was admitted a Fellow of the Royal Society. It was not until 1859 that he was appointed medical adviser to the India Office, with the rank of Inspector-General; his public services up to that time had been considerable, and his valuable volume on "The Influence of Tropical Climates" had then made his name known wherever English medical literature is read, and will no doubt long be considered a classical work.

After a year's service at the India House he was knighted, and also received the Companionship of the Bath.

It was thought by many that he ought to have been made a K.C.B., and at a later period Mr. Sidney Herbert, as War Minister, actually recommended him for that distinction. It was not, however, granted at the time; and it has been suggested that his retirement would afford the present Government an opportunity of remedying the omission: the delay has, however, been too long, and death has stepped in to prevent it. The proverbial neglect of the profession by successive governments is thus once more illustrated. A man may toil in the British Medical Service for nearly sixty years—may confer inestimable benefit on his fellows—may attain the highest fame—and may, if only a doctor, receive no further recognition of his services than many a so-called competent officer who has never been in any engagement, but has the luck to have influential connections. The lesson is one we have often enforced before. We submit it again to those who may have been responsible for the injustice, and some of whose names will be forgotten when the memory of Sir Ranald Martin will remain as fresh as now. After all, he did a good work, and his fame has long been secure—indeed, he lived to reap a very substantial reward in the well-nigh universal confidence of his professional brethren.

## Correspondence.

### HOSPITAL SATURDAY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Can you spare a corner for a few lines respecting the remarks in your last issue on Hospital Saturday. Agreeing fully with the idea that the working classes were not satisfied with the *bona fides* of the machinery employed for the purpose of gathering their subscriptions, I cannot endorse the assertion that they prefer spending their money in the public-house. I know full well the shortcomings of the class to which I belong, and also their good deeds. Any charitable matter which may require their aid, and of which the *bona fides* are satisfactory, meets with their hearty support, even to saving from public-house expenditure; but, although their wages may be “enormous,” if they have a doubt of the judicious expenditure of their contributions, they very properly stand aloof. The benefits of the hospitals they are not slow to recognise, and, as occasion may arise, support; I know that full well: but with regard to the movement under discussion, an impression had gone abroad amongst them that the Temperance Hospital would not share the proceeds, which was true of the Sunday collection; and when an impression once takes hold of them it is difficult to remove it. The teetotallers, I have no doubt, did not give largely to the Saturday fund; not because they prefer “beer and ‘bacca,” but because they mean to support their own hospital, since the Sunday Hospital Committee excluded that establishment. And if the charge be true of mispending their “large” wages, will the medical faculty aid us in teaching them better? When the medical men and the clergy abstain from opposing the temperance movement better things may be expected from the too-much petted and too-much maligned “working man.” I send you a Resolution passed by Good Templars, in hope that your noble profession may help us in the endeavour to benefit our own order, which will react on society at large, and in due time abolish these miserable class prejudices.—I am, Sir, yours faithfully,

A WORKING MAN.

58 Poland Street, Oxford Street,  
Nov. 20, 1874.

### MEDICAL MEN AND THE PRESCRIPTION OF ALCOHOL.

The “Prince Llewellyn” Lodge (1,404), of Liverpool, has just adopted an important resolution on this subject, copies of which are being forwarded to the medical men of the neighbourhood, accompanied by an appropriate letter under the signature of Bro. J. Mathias, W.C.T. The resolution is as follows:—

“That, viewing the many and very serious evils caused to many of our members, arising and resulting from ‘the pre-

scription of alcoholic liquors (intoxicants) during times of sickness’—especially to those of them who were once immoderate or confirmed drunkards, the taste of which liquors to them is sufficient to rekindle within them

that demon, the insatiate appetite for these drinks, which, as we have known in many, will drag them down once more into the lowest depths of vice and degradation—so low, alas! as to make it next to impossible to reclaim them again to the paths of sobriety, truth, and virtue; the greatest number of whom are never reclaimed, but go down lower and lower, until eventually they fall into a drunkard’s grave and go to a drunkard’s doom,—what responsibility!—viewing this momentous fact, we most respectfully plead with you, as with all medical gentlemen within our locality, to at least use extra caution ere you recommend such drinks to any of our members when under your care; we would even plead for non-alcoholic treatment in all such cases.”—*Good Templars’ Watchword*, Nov. 12.

### THE PEN VACCINATOR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DR. GEO. ED. NICHOLAS, of Wandsworth, takes the advantage of the favourable notices of my new invention, the “Pen Vaccinator,” which has appeared in several of the medical journals, to draw the attention of the profession to his “Vaccine Injector,” which he has resuscitated after eighteen years of oblivion.

It seems that Dr. Nicholas and I are each of us indebted to the well-known mathematical drawing-pen for our idea of a vaccinating instrument. While, however, I admit that his adaptation is antecedent to mine, I deny that the pen vaccinator is a modification, slight or great, of the vaccine injector, the existence of which latter instrument I was first made aware of by Dr. Nicholas’s recent letter.

Permit me, Sir, to say, that among the advantages I proposed to embody in my adaptation of the drawing-pen to the purposes of vaccination were an apparatus capable of carrying with it a reserve of lymph in capillary tubes or on ivory points, the blades of which should hold a charge of moist lymph for a considerable time without rust or corrosion, the whole to be in a portable form for carrying in the waistcoat-pocket. These points are all included in the pen vaccinator, but not one in the vaccine injector, the illustration which accompanied the letter of Dr. Nicholas in your issue of the 25th inst. being merely that of a mathematical drawing-pen without alteration, excepting in name.

Anyone who takes the trouble to glance at the illustrations will see at once that the two instruments are widely different.

I am, Sir,

Your obedient servant,

R. HARVEY HILLIARD, M.D.

5 Belgrave Terrace, Upper Holloway,  
Nov. 26th, 1874.

## Medical News.

Royal College of Surgeons of England.—The following gentlemen, having passed the necessary examination, were duly admitted Members of the College on the 19th ult:—

Barker, Henry Martyn, Bedford.  
Bate, George, L.S.A., Camelford, Cornwall.  
Bedford, Charles F., Sleaford, Lincolnshire.  
Blackmore, George Henry, Hammersmith.  
Cor, William W., M.D., Lee, Kent.  
Dryland, William, Dulwich, Surrey.  
Ellerton, John F. H., Huddersfield.  
Gravely, William Holmwood, Horsham, Sussex.  
Hoffmeister, John Bates, Cowes, Isle of Wight.  
Oakendon, Arthur John, Brighton.  
Parkinson, John Rendall, Preston.  
Phillips, Arthur O. H., Newcastle Emlyn.  
Roberts, Theophilus L., Alfreton, Derbyshire.  
Ross, William A., Alderney.  
Sheehy, William H. P., Claremont Square.  
Verco, Joseph Cooke, Ovington Street, Chelsea.

Wandby, William, Mile-end Road.  
Waller, William B., L.S.A., Sydenham.

Of the 92 candidates examined, 18 failed to satisfy the Court of Examiners, and were referred for six months' further professional study.

The following passed the first part of the professional examination for the Fellowship on the 24th and 25th ult. :—

John Morgan, Bristol and Guy's Hospital; Francis Joseph Davies, University College; Joseph Wm. Anningson, Manchester; Henry Ambrose Lediard, Edinburgh; Rutherford, J. Pye-Smith, Robt. Edmund Carrington, and Edward Amphlett, Guy's Hospital; William Harrison Cripps, Charles Firth, Hugh Gordon Cumming, and William Gammon Archer, St. Bartholomew's Hospital; J. H. Morgan and Henry Blake, St. George's Hospital; Robert Henry Clarke, Cambridge and St. George's Hospital; Thomas Cranston Charles, Belfast; Ernest Tredennick, James A. M. Moullin, Henry Percy Potter, and George Henry Makins, St. Thomas's Hospital.

Of the 39 candidates examined, 20 failed to satisfy the Court, and were referred for six months' further anatomical and physiological study.

**University of London.**—Candidates who passed the recent second M.B. examination for Honours :—

#### MEDICINE.

##### First Class.

Gould, Alfred Pearce (*Scholarship and Gold Medal*), University College.  
Duncan, Andrew (*Gold Medal*), King's College.  
Eastes, Thomas, Guy's Hospital.  
Duncan, Peter Thomas, University College.

##### Second Class.

Sturge, William Allen, University College.  
Rigby, James Arthur, Guy's Hospital.  
Crocker, Henry Radcliffe, University College.

#### OBSTETRIC MEDICINE.

##### First Class.

Gould, Alfred Pearce (*Scholarship and Gold Medal*), University College.  
Duncan, Andrew (*Gold Medal*), King's College.  
Eastes, Thomas, Guy's Hospital.

##### Second Class.

Rigby, James Arthur, Guy's Hospital.  
Duncan, Peter Thomas, University College.  
Sturge, William Allen, University College.  
Branfoot, Henry Seymour, Guy's Hospital.  
Crocker, Henry Radcliffe, University College.

##### Third Class.

Nicholson, Arthur, King's College.  
Harris, Vincent Dormer, St. Bartholomew's Hospital.  
Whittle, Edward George, University College.

#### FORENSIC MEDICINE.

##### First Class.

Crocker, Henry Radcliffe (*Scholarship and Gold Medal*), University College.  
Gould, Alfred Pearce (*Gold Medal*), University College.  
Duncan, Peter Thomas, University College.

##### Second Class.

Duncan, Andrew, King's College.  
Eastes, Thomas, Guy's Hospital.

**Hospital Saturday.**—At a meeting of the Council, held on Saturday, at the Central Offices, Leicester Square, Captain Mercier, the Chairman of the Fund, presiding, the distribution of this year's Hospital Saturday collection was considered; and on the motion of Mr. George Odger, seconded by Mr. Patrick Kenny, it was resolved to issue to the hospitals and dispensaries a form containing a series of questions, with the understanding that in the event of the form not being returned by the 16th of December, the Council will assume that the institution concerned does not wish to participate in this year's distribution.

**Hospital Sunday in Devonshire.**—On Sunday last, at the instance of the bishop of the diocese, an appeal was made in all the churches of Devonshire on behalf of the County Hospital at Exeter. Most of the nonconformist ministers also, in response to a request of the high sheriff of the county, appealed to their congregations in support of the funds of the same institution. The preacher in the cathedral, Dr. Boyd, made some very opportune remarks, which go to confirm the statements recently made by us, and which have been impugned in certain interested quarters. He said that in the administration of charities there was a great deal of mismanagement, a very large proportion failed to reach the objects intended, and secretaries' salaries, luxurious offices, and things that came under the head of fire, stationery, and fees, swallowed up a very large percentage of what was contributed for the relief of destitution. Another difficulty was lavish and indiscriminate administration of charity. He then adverted to the habits of the working classes, who, he alleged, spent £75,000,000 a year in drink. The two great trades of England were cotton and woollen manufactures. In 1840 there were working in woollen manufactories 334,640 persons at 10s. per week. Their annual income would be £3,670,000; add one-fifth for increase in wages and population, and the income would now be £10,176,000. Many did not work more than four days a week, and it might fairly be said that men in this trade struck off, by waste of time, on "idle Monday," one-sixth of what they could earn, or at least £1,600,000. In the cotton trade in this country there were 800,000 persons. Take the average wages in 1840 at 12s. 6d. per week, and their income would be £26,000,000; add one-fifth for increase of population and wages, and the income would now be £31,200,000. On an average these people spent one day a week in voluntary idleness, and this threw away £5,200,000. Bricklayers wasted £500,000 a year in the same way. Let working men substitute industry for idleness and they would soon have the means of supporting charitable institutions. They should support them because they were the principal recipients of the bounty, and because they could do so if they chose to be sober instead of drunken, and industrious instead of idle.

## NOTICES TO CORRESPONDENTS.

MR. ALEXANDER LANE.—In our next.

DR. PAVY is thanked.

IGNOBAMUS.—Another name for potasse carbonas. It is obtained by treating ordinary commercial pearlash with its own weight of distilled water and evaporating the solution so formed to dryness. Dose, 10 to 30 grs. 2. We cannot find the person named in either the "Medical Register" or "Directory."

MR. HUTCHINSON.—The address has been filled in, and the note sent to Dr. R.

DR. BELL TAYLOR's letter is unavoidably held over to our next.

#### MEDICAL ETHICS.

—"Quis custodiet ipsos Custodes?"

Juv. VI., 347.

SOME years since the daughters of one of our most distinguished orators and dramatists were denominated the three graces, being respectively all grace, graceless, and disgrace. Of the three blank graces—Divinity, Law, and Physic—it is not difficult to guess to which category Physic may be assigned. The everlasting cry of the "dignity of the profession" indicates the necessity of its members sounding their own trumpets with peans in celebration of "honour" and "etiquette," lest the public should penetrate the almost diaphanous artifices adopted to achieve individual popularity. As a culmination, on June 16th, 1873, the following circular emanated from the Royal College of Physicians, London :—

"DEAR SIR,—I have the honour to forward the subjoined resolutions, which were adopted at a general meeting of the College held on the 9th inst. :—

"I.—That the practice of medical authors frequently advertising their own works in the non-medical journals, and especially with the addition of laudatory extracts from reviews, is not only derogatory to the authors themselves, but is also injurious to the higher interests of the profession.

"II.—That the above resolution be communicated to the President of the Royal College of Surgeons, and to every Fellow and Member of this College.

"I have the honour to be, dear Sir,

"Yours faithfully,

"HENRY A. PITMAN, Registrar."

This remarkable remonstrance against the practice of advertising medical works in the public journals was singularly stultifying on the part of the general meeting, i.e., of the *Fellows* of the College, many of whom have scaled the ladder of membership, and ascended through advertising and consequent notoriety to the fellowship election which (to speak sans personality) is influenced in the opinion of numerous distinguished members, by absolutely inscrutable reasons; so much so that two eminent licentiates, originally so-called, Sir James Clark and Dr. Neil Arnott, declined the equivocal elevation. With admirable

VACANCIES.

Royal Free Hospital, London. Senior House Surgeon. Salary, £104 per annum with board and residence. Testimonials and applications to be sent to Mr. J. S. Blyth, at the hospital.

Bridgnorth Infirmary. House Surgeon. Salary, £100 per annum, with furnished apartments. Applications to the Hon. Sec. before the 8th inst.

Nottingham General Hospital. Physician. Honorary. St. Luke's Hospital, London. Clinical Assistant. Board and residence, no salary. Address the Secretary.

Marylebone General Dispensary. Physician. Honorary. Woolwich Union, Kent. Assistant Medical Officer to the new Infirmary at Plumstead. Salary, £80, with board and residence. Applications under cover, to the Clerk to the Board.

Ashton-under-Lyne. House Surgeon to District Infirmary. Salary, £80, with board and residence. Applicants must address Mr. Hugh Mason, Ashton.

Bristol Infirmary. Additional Medical Officer. Salary commencing at £150 per annum. Full particulars of the Secretary.

Gainsborough Union. Medical Officer for the Willingham District, at £70 per annum, fees extra. Also Registrar of births and deaths. Applications to the Clerk of the Board.

Bromyard Union. Medical Officer for District No. 1, at £120; for District No. 2, at £100; and for the Workhouse, at £30 per annum. Mr. Knott, the Clerk, will supply full particulars.

Trinity College, Dublin. Professorship of Chemistry in the School of Physic. Fixed salary, £400 per annum, with other emoluments. (See Advt.)

APPOINTMENTS.

ALLEN, J. B., L.K.Q.C.P.I., Superintendent Medical Officer of Health for the Gorey Rural Sanitary District.

BARRY, G. P., M.D., Superintendent Medical Officer of Health for the Kanturk Rural Sanitary District.

BODKIN, P. J. T., L.K.Q.C.P.I., Superintendent Medical Officer of Health for the Glennasmaddy Rural Sanitary District.

BRADBROW, R., L.K.Q.C.P.I., Superintendent Medical Officer of Health for the Carrick-on-Shannon Rural Sanitary District.

BURKE, J. G., L.K.Q.C.P.I., Superintendent Medical Officer of Health for the Dublin South Rural Sanitary District.

CAMERON, C. A., M.D., Medical Officer of Health and Analyst for the Dublin Urban Sanitary District.

CURRY, J. E., M.D., Superintendent Medical Officer of Health for the Lismore Rural Sanitary District.

GIVEN, G. K., M.D., Superintendent Medical Officer of Health and a Sanitary Officer for the Gortin Rural Sanitary District.

HEPBURN, D., L.D.S.R.C.S.E., Dental House Surgeon to the Dental Hospital of London.

JOHNSTON, A. M.B., Superintendent Medical Officer of Health and a Sanitary Officer for the Westport Rural Sanitary District.

KELLY, J. T., L.R.C.S.I., Superintendent Medical Officer of Health and a Sanitary Officer for the Glenties Rural Sanitary District.

LANGAN, F., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer, &c., for the Shercock Dispensary District of the Baillieborough Union, co. Cavan.

M'DONNELL, C., L.R.C.P.Ed., Superintendent Medical Officer of Health and a Sanitary Officer for the Glm Rural Sanitary District.

Marriages.

BROWN—BROWN.—On the 28th ult., at Eaton Bishop, Hereford, by the Rev. Samuel Clark, M.A., Rector, W. W. Brown, of Falklands, Dorset, to Catharine, widow of I. Baker Brown, F.R.C.S. No cards.

Deaths.

BENT.—On the 23rd Nov., at Aldershot, Surgeon-General John Bent, Army Medical Department, in the 58th year of his age.

CUMMING.—On the 19th Nov., at Glasgow, Wm. Cumming, M.D., of Wigtown, aged 33.

HAYWARD.—On the 19th Nov., Geo. Hayward, M.D., of Ealing, formerly of Leeds.

HUNTINGTON.—On the 15th Nov., F. Huntington, F.R.C.S.E., of Hull.

MARTIN.—On the 27th Nov., at 37 Upper Brook Street, Sir J. Randall Martin, C.B., F.R.S., aged 81.

MITCHELL.—On the 15th Nov., at Pentney Vicarage, Norfolk, Thos. Robinson Mitchell, M.D., of Jarrold-on-Tyne, aged 58.

RAYNER.—On the 9th Nov., A. P. Rayner, M.R.C.S.E., of Shawbury, Salop.

SEYMOUR.—On the 21st Nov., at Surbiton, Maria, widow of Edward James Seymour, M.D., F.R.S., in her 78th year.

STEVENS.—On the 5th Nov., J. N. Stevens, M.R.C.S.E., of Princess Place, Plymouth, aged 63.

Advertisements.

SOCIETY for RELIEF of WIDOWS and ORPHANS of MEDICAL MEN.—Founded 1788.—Incorporated by Royal Charter 1864.—The MEMBERS are reminded that a QUARTERLY COURT of DIRECTORS will be held on the 13th JANUARY, 1875. Candidates for admission into the Society desirous of being balloted for at the Meeting must send their form of proposal to the Secretary on or before December 22. The form of proposal may be obtained of the Secretary. The benefits of the Society are restricted to the families of deceased Members of not less than two years' standing. The Secretary attends at the office every Wednesday and Friday, from 4 to 5 o'clock.

J. B. BLACKETT, Secretary.

53 Berners Street, W., December 2, 1874.

ROYAL FREE HOSPITAL, GRAY'S INN ROAD.—The office of SENIOR HOUSE-SURGEON to this Hospital is now vacant. Candidates must be possessed of a medical or surgical qualification from one or more of the Examining Boards of the United Kingdom, rendering them eligible for registration under the Medical Act. The salary is £104 per annum, with board and residence in the Hospital. The appointment will be made for twelve months only, but the holder will be eligible for re-election. The engagement will be terminable by three months' notice on either side. Preference will be given to a candidate who has had experience in a similar capacity. Candidates are requested to send in their testimonials to the Secretary on or before WEDNESDAY, the 9th DECEMBER, 1874.

JAMES S. BLYTH, Secretary.

MALVERN COLLEGE.

This COLLEGE contains TWO DEPARTMENTS—the CLASSICAL and the MODERN. There is also a Preparatory LOWER SCHOOL.

There are Boarding Houses within the College Grounds, held by the Head Master and others of his Staff; a Gymnasium, &c.

Board and Tuition under 14, £80; over 14, £90. Non-shareholders pay an extra fee of £6. Special advantages for Sons of Clergymen and Home Boarders.

For further information apply to the Rev. ARTHUR FABER, M.A., Head Master, late Fellow and Tutor of New College, Oxford.

The Examination for Scholarships and Exhibitions on December 22nd and 23rd.

TRINITY COLLEGE, DUBLIN.—SCHOOL of PHYSIC IN IRELAND.

Pursuant to the provisions of the School of Physic Act, 40 Geo. III., ch. 24, and Amendment Act, 30 Victoria, ch. 9: Notice is hereby given that the Professorship of Chemistry in the School of Physic became vacant on the 3rd of OCTOBER, 1874; and that on SATURDAY, the 30th JANUARY, 1875, the Provost and Senior Fellows of Trinity College will, at the hour of twelve of the clock (noon), in the Board-room of the said College, proceed to elect a Professor of Chemistry, in the room of Professor James Apjohn, resigned.

The Emoluments and advantages of the Professorship consist of the following items:—

- 1st. A fixed salary of £400 per annum.
- 2nd. An additional payment of £100 per annum, on condition that the Professor shall give free Laboratory instruction to such Senior Sophisters as shall be nominated by the Bursar.
- 3rd. Fees for Lectures and Laboratory Instruction, to be regulated from time to time by the Provost and Senior Fellows.

N. B.—The fees as at present arranged are—  
Medical Lectures (Winter Course) . . . £3 3 0  
Medical Practical Course (Summer) . . . £1 5 0  
Laboratory Course (eight months) . . . £10 10 0

Graduates in Arts, and Students whose names are on the College books, are admitted to the Medical Courses on payment of half the above fees.

- 4th. The Professor shall have the use of the College Laboratory for analyses bearing on Medical Chemistry, and approved by the Provost and Senior Fellows, such as Medical and Medico-legal investigations, and analyses connected with purposes of Public Health.

All Candidates are required to send their names, with the places of their education, the Universities where they have taken their Medical Degree, and the places where they have practised, to the Registrar of Trinity College, Dublin, and the Registrar of the King and Queen's College of Physicians in Ireland, on or before Saturday, the 23rd January, 1875.

Candidates wishing for further information are requested to communicate with the Rev. Dr. HAUGHTON, Medical Registrar, Trinity College Dublin.

ANDREW S. HART, Registrar, T.C.D.  
J. MAGEE FINNY, Registrar, K. & Q.C.P.

DUBLIN INFIRMARY for DISEASES of the EYE and EAR, Ely Place.

Ophthalmic and Aural Surgeon:  
ARCHIBALD HAMILTON JACOB, M.D. Dub., F.R.C.S., Ex-Ophthalmic and Aural Surgeon to the City of Dublin Hospital.

Consulting Physician:  
EVERY KENNEDY, M.D. (Hon. Caus.) T.C.D. and Edin., Fellow and Ex-President King and Queen's College of Physicians.

Consulting Surgeon:  
GEORGE H. PORTER, F.R.C.S.I.; M.Ch. T.C.D. (Hon. Caus.), Surgeon in Ordinary to Her Majesty the Queen in Ireland; Fellow and Ex-President, R.C.S.I.; Senior Surgeon to the Meath Hospital.

Obstetric Physician:  
JOHN CRONYN, M.D., F.R.C.S., Examiner in Midwifery, Roy. Col. Surgeons; Ex-Assistant Physician Rotunda Hospital.

Work, Income, and Expenditure for Twelve Months, ending June 30, 1873.

Annual number of Dispensary patients	...	...	...
Number of visits paid by such patients	...	...	5,847
Number of patients within the Infirmary	...	...	124
Number of operations performed	...	...	163
Total gross expenditure per bed per annum	...	...	£27 15 0
Average expenditure per intern patient	...	...	1 10 6

The Infirmary is wholly dependent on private benefactions, and is in debt to the Medical Officer. SUBSCRIPTIONS ARE EARNESTLY REQUESTED

### ON THE SCIENTIFIC AND EMPIRICAL INVESTIGATION OF EPILEPSIES.

By J. HUGHLINGS JACKSON, M.D., F.R.C.P.,

Physician to the Hospital for the Epileptic and Paralyzed, and to the London Hospital.

#### CHAPTER III. (continued).

I WILL now take an example more striking than any. There is, I consider, an essentially similar functional condition of nervous tissue in epileptic mania, in epileptic aphasia, and in epileptic hemiplegia. As I have already, for another purpose, spoken of epileptic mania (Chapter II., page 409), and have at the same time spoken of epileptic hemiplegia, I must speak briefly here. In each of the three there is temporary exhaustion of a nervous tract after, and as the result of, an excessive nervous (i.e., epileptic) discharge. In the first instance that tract consists of processes underlying consciousness in the second of processes of the speech series, and in the third of processes for movements of the limbs, &c. (the corpus striatum). (a)

But clinically, the cases are extremely different, especially the condition of the extremes, that of the epileptic maniac and of the hemiplegic man. It would be absurd to put the man who is raving and the man who is hemiplegic in the same ward for care simply because from a scientific standpoint they are fundamentally alike. They would require different kinds of supervision. It would be absurd also to treat them in the same way; one patient would require

(a) The nomenclature here is confusing. The mania in epileptic mania is not the analogue of the epileptic aphasia or epileptic hemiplegia. There is a duplex condition in each. Loss of consciousness in the epileptic maniac is the analogue of the loss of speech and of the hemiplegia. These are the three negative elements. Now for the three corresponding positive elements. The mania is the positive element in the first. The positive elements in the other two (the analogues of the mania) are conservation of the more automatic factors in language (smiling, laughing, &c.) and conservation of all movements more automatic than those of the face, arm, and leg.

to be put to sleep, the other would not. That each was suffering from an essentially similar morbid functional state (exhaustion of part of his brain, the consequence of a strong nervous discharge) makes no difference for empirical or practical arrangements. It would be as absurd to consider the two cases as alike for practical purposes as it would be for a gardener to put his plants together, not as fruit trees, ornamental shrubs, &c., but according to the division Rosaceæ, Cruciferae, &c. So much for the clinical investigation and arrangement. Now for the other side—for the value of the scientific investigation and classification. I do not see how we are to understand the very complex problem of epileptic mania until we have studied it in relation with the simpler one of epileptic aphasia, and the still simpler one of epileptic hemiplegia. We must make a comparative study of them, and to do this we must reduce the cases to their lowest terms. We must, in other words, classify them on a fundamental basis, as depending on exhaustion of nervous tracts, that is as after-effects of epileptic discharges. It is as justifiable for scientific classification of our cases of disease to underrate superficial differences when we can trace fundamental resemblances as it is for the botanist to put together a lily, a tulip, an onion, and the asparagus plant, or for a zoologist to classify a whale, a bat, a hedgehog, and an elephant as mammals.

I think a good illustration of the two kinds of classification and methods of investigation may be taken from insanity. I have the less hesitation in giving it, as when I come to speak at length on epileptic mania, I shall have to speak generally of insanity. It is a part of my subject, for epileptic mania is acute temporary insanity.

There are very many classifications of Insanity, and this is good evidence of the difficulty in dealing with the complex problems the cases present. For my part, I think we should have Arrangements of Cases of Insanity for practical purposes, and a Classification on some natural system for the purpose of increasing our knowledge of "diseases of the mind." The arrangements, entirely artificial, would only be provisional. They would in asylum practice start with the very general definition of a lunatic as a person who requires restraint on account of mental disorder. The arrangements would vary very widely as the cases were

considered from a pathological or therapeutical point of view, or as the patients required different degrees and kinds of supervision. If a certain kind of insanity were often found along with phthisis, this would be a good reason for making a group "phthisical insanity" for treatment, and also for the accumulation of otherwise unrelated facts bearing on pathology. If the patient were suicidal, there would be very good reason for taking that to be the leading feature of his case for certain practical purposes. Then the grouping epileptic (a) insanity is a very useful one. But for increasing our knowledge of insanity and, indirectly, of mental operations in health, these practical arrangements alone will not suffice. We require also a theoretical arrangement, or rather a classification properly so-called—in fact, a classification on a natural system.

Cases of insanity should, I think, be classified and investigated on the basis supplied by the doctrine of Evolution of nervous centres. We shall have enormous help in the work Spencer has done in his "Psychology." We have already explained that we use the term Dissolution as the opposite of Evolution. Insanity is Dissolution beginning in the highest nervous processes. The highest processes form the anatomical substrata of consciousness. In insanity there is partial or total loss of use of the highest processes, the symptom being loss or "defect" of consciousness. Metaphorically speaking, the disease is of the controlling processes. These are negative statements. There is stated from the positive side, reduction to a more automatic condition of mind, or, physiologically stated, a "lowering of adjustment." (See Chapter II., Part 2, Oct. 21, page 350.) The elements of the duplex condition, dissolution and automatic action, are in inverse proportion. The "shallower" the dissolution, the higher and more special (more nearly normal) is the automatic mental action permitted; the deeper the dissolution, the more general is the automatic action. The ravings, grotesque actions, visual and auditory hallucinations, &c., are due to action of centres which, except for over-excitement from loss of control, are healthy.

The varieties of insanity would be explained (1) by the depth of the reduction or dissolution; (2) by the rapidity of the reduction; (3) by the kind of brain in which the reduction occurs; and (4) by the influence of external circumstances and internal bodily states on the patient who is reduced. These factors will vary in relative amount infinitely. Insanity is a Function of four Variables.

Moreover, of course, what we here call the Scientific Investigation of Insanity is really an experimental investigation of Mind; and in this regard the slightest departures from a person's standard of mental health are to be studied, and not only the cases of patients who require to be kept in asylums; indeed, the slighter cases (e.g., the cocoa-mixing affair—see page 410) are the more important in the scientific investigation. For whilst in studying Evolution we study from the general to the special, it is easiest to study in the reverse way the effects of Dissolution. For example, the more special (the more nearly normal) the mental automatism after an epileptic discharge is, the easier is it understood. The cocoa-mixing automatism is a more valuable experiment on mind than is a case of epileptic mania.

Although for convenience we used above the conventionally correct expression investigation of "diseases of the mind," we mean, of course, as has been also explicitly stated, investigation of those diseases which begin in the highest centres of the nervous system. We have to do with changes in nerve cells and fibres making up sensori-motor processes, which are not mind, but only the substrata of mind. Strictly speaking, it is as erroneous to say that the insane patient has disease of the mind as to say that a

patient the subject of simple and incipient optic atrophy who cannot see red has "disease of colour." It is exceedingly important to get rid of the psychological implication which the convenient expression "disease of the mind" has. Our concern with mind is indirect. Now, in an anatomico-physiological inquiry on the principle of Evolution we do not make any abrupt limit to nervous processes serving in mind. We look on the whole nervous system as made up of processes for the co-ordination of impressions and movements. Why, during the energising of some of the highest and most special of these, mental states arise, we do not inquire. In Dissolution there are all gradations traceable as a consequence of disease (for example, exhaustion after epileptic discharges) beginning in the highest centres, from such slight "depths" of dissolution as those which permitted actions so nearly normal as the cocoa-mixing affair (see p. 410), to dissolution so deep as coma, in which there is no evidence of mentation, and but the most general and most automatic physical action. For, I repeat, in an anatomico-physiological inquiry the question is not the psychological one—Is consciousness displayed? but, How is the organism adjusted to its environment? We have to trace all degrees of defective adjustment corresponding to different depths of dissolution. In the cocoa-mixing affair the adjustment was almost as special as is normal; in mania where the dissolution is deeper it is far more general; and in deepest coma the adjustment is of the most general character compatible with life.

Epileptic mania is acute temporary insanity, but in insanity ordinarily so-called there is clinically an essentially similar double state. There is defect of consciousness analogous to loss of consciousness, and there is slightly increased automatic action analogous to the raving. The difference in degree depends, I believe, on the second Variable (*vide supra*), on the difference in the rapidity with which the dissolution is effected (control removed). Dissolution is effected with extreme rapidity by an epileptic discharge, whereas in insanity ordinarily so-called the morbid process removing or impairing control is usually very slow indeed.

That the insane patient has defect of consciousness cannot, I think, be doubted; for example, in a patient who has illusions or delusions (positive or active element) there is really, I uphold, a negative or passive element—affection of consciousness. The cases are, however, always spoken of from the positive element only. The negative is the more important medically. The patient who has a delusion has it for the same reason that the dreamer has delusions. There is in each loss of ability to correct automatically arising mental states (which are very active) by objective states, because, since the processes serving in the latter are implicated, clear objective states are not possible. Speaking technically, the Judgment is defective. The nervous processes implicated are those which form the anatomical substrata of consciousness, or, otherwise expressed, those by which the organism, as a whole, is adjusted to its environment. There is in insanity a less special, or, otherwise put, more general adjustment. The man who in hospital imagines himself to be at his home has defect of consciousness, and, as a consequence, also lowering of adjustment; his automatically arising states are not corrected by objective states. He is in a dream from which awakening is sometimes not possible. There are degrees from the very slightest and most temporary departures from healthy mental states to dementia, which, so far as it shows implication of processes serving in mind, is the analogue of coma. (a)

It is of much importance to my argument in many parts of this book to show that defect of consciousness is, on its anatomico-physiological side, defective correspondence with the environment. I would refer the reader to the quotation from Spencer in the first Appendix to the last chapter (p. 412). I now give a further quotation from his "Psychology" on what takes place in healthy mentation.

(a) No doubt these degrees are (like increasing degrees of hemiplegia) "compound degrees." The more the special processes are affected, the wider is the implication of the more automatic.

(a) We have, of course, to distinguish betwixt (1) transient mania following an epileptic paroxysm, (2) the more lengthy mental infirmity after a succession of attacks, (3) the persistent deterioration which is a gradual result of seizures often repeated for months and years.

" . . . we pass into the domain of Psychology the moment we inquire how there comes to exist within the organism a relation between *a* and *b* that in some way or other corresponds to the relation between *A* and *B* [in the environment]. Psychology is exclusively concerned with this connection between (*A B*) and (*a b*)—has to investigate its nature, its origin, its meaning, &c.

"A moment's introspection will now make it clear to the reader that he cannot frame any psychological conception without thus looking at internal coexistences and sequences in their adjustments to external co-existences and sequences. If he studies the simplest act of perception, as that of localising a touch in some part of his skin, the indispensable terms of his inquiry are—on the one hand, a thing (1) and a position (2), both of which he regards as objective; and on the other hand a sensation (3), and a state of consciousness constituting his apprehension of position (4), both of which he regards as subjective. Again, to cite an example from the opposite extreme, if he takes for his problem one of his involved sentiments, as that of justice, he cannot represent to himself this sentiment, or give any meaning to its name, without calling to mind actions and relations supposed to exist in the environment; neither this nor any other emotion can be aroused in consciousness even vaguely without positing something beyond consciousness to which it refers. And when, instead of studying Psychology subjectively, he studies it objectively in the acts of other beings, he similarly finds himself incapable of stirring a step without thinking of inner correlations in their references to outer correlations." ("Principles of Psychology," vol. i., p. 133.)

(To be continued.)

## ON THE TREATMENT OF FISTULOUS SINUSES BY MEANS OF THE ELASTIC LIGATURE. (*a*)

By W. ALLINGHAM, F.R.C.S.,  
Surgeon to St. Mark's Hospital, &c., &c.

(Continued from page 482.)

THE elastic ligature is sometimes very advantageous as a supplement to the knife—for example, it is not uncommon to find, after laying open a comparatively superficial sinus, that from the floor of this sinus another one runs deeply, even beneath the internal sphincter up the bowel to a greater or less distance. To secure the patient's recovery it is absolutely necessary to lay this deep sinus freely open, and in doing this you may sometimes get severe hæmorrhage, which will give more or less trouble both to the surgeon and the patient. Here the elastic ligature comes in most usefully. Lay every sinus that is superficial open with the knife, and then pass a ligature through the deep sinus, and this is thus dealt with in a most satisfactory manner. In a very extensive fistula in a gentleman of phthisical tendency, a patient of Dr. Corbett Blades, of Kennington, upon whom I operated for Dr. Blades in July last, after laying open several long but superficial sinuses, I found two deep burrowings under the internal sphincter on both sides of the bowel. These passed up at least three inches. Feeling confident that in laying these open I should expose the patient to a considerable loss of blood, and considering his weak delicate state, I at once determined to apply elastic ligatures, and did so. The result has been all that one could have wished, and much more than could have been expected: the ligatures cut their way out in about nine days; the pain was not great; no secondary abscess formed; there was no further burrowing; and when I saw the patient, some short time back, he was greatly improved in health, had become quite stout, and the fistulæ were all soundly healed. A very

satisfactory fact also is, that although such large and free divisions of both sphincter muscles on both sides of the rectum had been made, he retains good control over his motions, and even over flatus.

In a very recent case operated upon by me in the practice of Dr. Elliot, of Denmark Hill, I used the ligature under precisely similar conditions, and with good result. Unless the patient be very much more than usually nervous, no anæsthetic need be given, and even if you cannot dispense with it entirely, a whiff of nitrous oxide will suffice, as in a favourable case the operation can be accomplished in something under ten seconds. No man is more alive to the value of anæsthetics than I am, nor more grateful to their discoverers; but I am always happier when able to dispense with them. You can truly assure your patient that the introduction of the elastic ligature through the fistula is almost painless, and, further, if you explain and show an intelligent person the *modus operandi*, you are almost certain to at once command confidence, and consequently submission to your wishes. It may be a ridiculous weakness, but the vast majority of human beings have a horror of the knife and so-called cutting operations, consequently, they are at once reassured when they learn that knives can be dispensed with, and I have now cured several patients of fistulæ who absolutely had determined not to submit to any "cutting operation," and who would have gone on possibly from bad to worse until health was undermined and eventually a very severe operation rendered absolutely indispensable, where a slight one earlier performed would have led to a cure.

In operations with the elastic ligature there is always an exceedingly small amount of supuration—much less pus proceeds from the wound than when it is made with the knife; few things have surprised me more than this in watching my cases. Until the ligature comes away there is scarcely more than a drop of pus to be seen. The wound granulates, contracts, and fills up in every way as the ligature passes through; for example—having carefully measured a sinus and found it 3½ inches in length, with an estimated depth of ¾ of an inch to an inch, when the ligature separated on the eighth day the wound left measured 1½ inch in length, and the depth was less than a ¼ inch. On the 18th day after the ligature had been put in the wound was soundly cicatrised throughout. An equally favourable result, I think I may safely say, considering the extent of the wound, I never saw follow the knife. I have said that in my opinion the india-rubber ligature does not so much cut as compress, so that when it comes away a portion of the roof of a sinus separates with it; thus the wound gapes, and the result is, a comparatively broad and shallow wound is left, which soon fills up and skins over. This is very desirable in fistula in ano, as you do not get any over-hanging edges, which fall into the wound, retain pus, prevent healing, and tend to cause burrowing. Thus, in operating with the knife on a fistula, if you only make a clean cut through its roof, you will often find that you have left a deepish wound with undermined edges. If you leave it in this condition it will be very long in healing, as it will be liable to unite instead of filling up from the bottom. You will have constantly to watch it, and put lint or wool into it to obviate this, and the constant dressing will be neither satisfactory to yourself nor your patient. Thus, in days gone by, you were always directed to stuff a fistula with oiled lint, and the frequent thrusting in of this lint greatly delayed, and often totally prevented cicatrization. When I operate with the knife in such a case, I most usually (and always when the edges are thin and flapping) remove both the edges, so as at once to form a broad and comparatively shallow wound. Thus, cicatrization immediately commences at the edges, and as the part is filling up by granulation, the skin creeps over the surface, and much time is saved. Such a wound requires scarcely any dressing, and certainly no stuffing with lint. Now, this is exactly what the ligature accomplishes, and I consider it no small advantage.

(a) Read before the Medical Society of London, November 2nd, 1874.

I will now give very briefly the notes of twenty of my hospital cases, taken without any selection, to exhibit the general character of their behaviour after the ligature, and make only such observations upon them as may appear quite needful.

CASE I.—Julia P., æt. 37. Complete fistula; operation January 12; ligature separated 8th day; very slight pain; cured in fourteen days.

CASE II.—Caroline C., æt. 32. Complete fistula; operation February 2; ligature came away 9th day (two hæmorrhoids were also ligatured); very little pain; cured in sixteen days.

CASE III.—Wm. S., æt. 23. Blind internal fistula; phthisical subject; two ligatures used; operation Feb. 28; ligatures came away the 7th day; went out well in eighteen days; much improved in general health.

CASE IV.—Wm. R., æt. 53. Blind external fistula; very deep and long sinus; operation March 16. The ligature required tightening on the 7th day, and came away on the 10th day. He had a good deal of pain after the tightening of the ligature. Discharged cured in twenty-six days.

CASE V.—Daniel C., æt. 47. Complete fistula; operation March 9; ligature came away 11th day; discharged cured in twenty-two days. He was a very delicate man, with a systolic bruit, having had rheumatic fever; suffered absolutely no pain; did not keep his bed at all.

CASE VI.—Abraham C., æt. 39. A deep and long complete fistula, commencing  $2\frac{1}{2}$  inches from the anus; the internal opening between the two sphincters; operation May 4; ligature separated on the 7th day. This man had a good deal of pain. He left the hospital at his own request twelve days after the operation, the wound then being no larger than a split horse-bean. This was a result far surpassing anything I ever saw from an operation with the knife.

CASE VII.—David A., æt. 52. Complete perineal fistula; operation April 25; ligature came away in eight days; cured in fourteen days; had no pain, and never kept his bed.

CASE VIII.—Lucy C., æt. 39. Blind external fistula; operation May 4; ligature came away in four days; had no pain; cured in twenty-six days.

CASE IX.—Henry O., æt. 27. Blind external fistula; operation May 11; not noted when the ligature separated. This sinus ran a long way up the bowel; he had absolutely no pain; discharged cured in fourteen days.

CASE X.—Fanny D., æt. 21. Double fistula. Two external and two internal openings on opposite sides of the bowel; operation June 1; ligature came away on 5th and 6th days; suffered a great deal of pain for several days. She was a weak hysterical woman; but I do not doubt her statement as to her having much pain. Poultries and morphia hypodermically administered relieved her; discharged cured in twenty-three days.

CASE XI.—Wm. C., æt. 30. Complete fistula; length of sinus  $3\frac{1}{2}$  inches; operation June 8; ligature came away in eleven days; good deal of pain the first night, but slept without an opiate; cured in twenty-two days.

CASE XII.—Elix. G., æt. 35. Complete perineal fistula running far into the labium (the labial sinus was laid open with the knife); operation on fistula with ligature March 23; the ligature came away on the 9th day; cured in thirty-four days. No pain after the operation for two days; but then she had great pain, and an abscess was discovered on the other side of the anus. This was at once opened, and it filled up without any further trouble.

CASE XIII.—George G., æt. 44. Very deep perineal fistula; operation May 4; ligature came away in ten days; had pain and retention of urine; cured in forty-five days. He was a very weak, delicate man, with a bad cough and phthisical tendency.

CASE XIV.—Christopher C., æt. 44. Complicated fistula; superficial sinus laid open with the knife; very deep one by the ligature; operation June 22; ligature separated 7th day; cured in twenty-three days.

CASE XV.—Henry S., æt. 24. Complete fistula; operation June 22; ligature came away in seven days. Had an impaction of fæces, which necessitated mechanical removal, causing him for the time great pain; discharged well in eighteen days.

CASE XVI.—George D., æt. 52. Complete dorsal fistula; operation Sept. 28; ligature came away 7th day; no pain. This was a very long sinus. He was discharged well in fourteen days.

CASE XVII.—Wm. B., æt. 52. Complete fistula; operation Oct. 5; ligature came away in nine days; had for two days a good deal of pain, but not enough to keep him awake at night, although he had no sedative. Cured in nineteen days.

CASE XVIII.—Jas. F., æt. 32. Blind external fistula; very thick bridge of skin; operation Jan. 19; ligature separated in five days; absolutely no pain; cured in twenty-three days.

CASE XIX.—Henry J., æt. 54. Complete fistula; operation Jan. 19; ligature cut through in six days; no suffering; quite well in fifteen days.

(To be continued.)

## INDIAN MEDICAL NOTES.—No. XXX.

MEERUT, November, 1874.

(FROM OUR SPECIAL CORRESPONDENT.)

SAHARUNPORE.

THERE'S some excuse for trifling with the pen to-day between the hospital visits, to wonder what remedies were used for gout in former days by Horace, Virgil, Ovid, Juvenal, Colley, Cibber, Congrieve, Fielding, Cowper, Sidney Smith. The Prince of Parma took the field in slippers; Pitt electrified the House of Commons; Lord Palmerston smiled away difficulties; and some say Kean, who ate boiled mutton for lovers', and pork for tragedy parts, fretted his little hour on the stage tortured by gout. Queen Anne, who hunted and lived far too generously, grew fat and gouty, and, when taken ill, sent for Radcliff, who, having gout himself, could not attend. Some said the Queen had ague, others diagnosed inflammatory fevers—tertiary postponed—or gout in the stomach; the symptoms, including palpitation, dyspnoea, vomiting, pain in the thigh, the fever somewhat influenced by bark, remitting in thirty-nine hours; erysipelas threatening, mortification followed, and though the patient enjoyed solid food, such as chicken, the end by coma soon followed. In the jog-trot humble walk of daily life many a medical man, in breaking health and broken spirits, can smile and wear the cheerful mask wonderfully pleasantly amid scenes depressing, and thus combat disease where others fail. We are told of the grand old Indian doctors who enjoyed none of the cooling appliances or modern comforts of to-day; some grew rich; others, such as Simon Nicholson, did not, though his practice and reputation left him no rest; at the bedside there was a healing power in his very presence, his kindness of heart, his indescribable manner: and when this bright, cheerful, and talented physician entered into the chamber of sorrow and suffering the terrors of sickness all but vanished. On the other hand, Akenside, so sweet, so gentle on paper, was a cantankerous crabbed physician in his hospital in London, disliked by the patients. Last year about 1,185 soldiers took to gardening, the number in 1872 being 572, showing increasing interest in the cultivation of fruits, flowers, and vegetables, a matter of the greatest medical importance in connection with the feeding of troops in India, where good meat may not be procurable, where cheap animal food is worse than none sometimes, and where good vegetables are so urgently re-

quired towards repairing the exhausting waste of fever. Turnips, carrots, parsnips may be woody, fibrous, the flavour of peas and onions very faint, yet the salads of mustard and cress, beetroot, cucumber, tomatoes, and native vegetables at Meerut are certainly appetising in the extreme. It is a matter of opinion whether the rearing of lovely flowers or graceful shrubs be healthy or not; the turning over of soil may induce fever, perhaps dysentery, which, extending to the liver, may there excite pyæmia, points constituting multiple abscesses, which no chloride of ammonium or pneumatic aspiration can relieve, for the liver may be riddled; and thankful I was the other that when the aspirator was out of repair, when the dead-house secrets afterwards were disclosed. No one can lay down any law of limitation of latent virulence in soils; for instance, a century after the plague at Eyam, some labourers, digging potatoes, caught and started malignant typhus, and in France, Germany, India, similar strange tales are told. Fevers puzzling, wasting, dangerous, intractable, leading to organic mischief; diarrhoea, dysentery, hepatitis, include the work just now. My commanding officer laid up with gout, requiring colchicum, iodide of potassium, podophyllin, citrate of lithia, iron, and quinine. My little apothecary, clever, reliable, ever at his post, is down with double pneumonia, often fatal to Eurasians. Every servant ill with ague, requiring money, brandy, opium, quinine; no work is done; the house and horses must go slide. There are better times in prospect. Eventually it is hoped that the cruel spectre malaria will be driven into the next parish, and the good old days revived when people fled from sickness and pestilence to Meerut. When the wind is in the east in sickly September or October it is easy to run off for a few hours by the railway and return refreshed to hopefully encounter work, however depressing. After the evening visit I can readily take up my bed and drive to Meerut Station, take the train to Saharanpore, sup at the station, sleep in the rest-house, arise early next day, spend a few hours in the Botanical Gardens, adjoining almost, and return by morning, or, if I can afford the time, the evening train to Meerut. These gardens, alluded to when Landour was visited, formerly belonged to a native prince, who, seventy years ago, started the place, now extending over 200 acres. The visitor familiar with Chiswick, Kew, and the Regent's Park, the Horticultural Gardens, the Crystal Palace grounds, and flower-shows generally, must make allowances for heat and climate, the chances are, Balaam fashion, he will return pleased, will bless instead of curse the place, which I found most enjoyable in the early morning, when the grass was wet with dew, the birds and insects singing and buzzing so merrily, some of the flowers still asleep—for instance, the twelve varieties of gorgeous, glorious passion-flowers; others, for instance, the great white mushroom-looking blossoms of the moon-flowers, which had an "up all night at a midwifery case" appearance, were jaded and worn; others, such as spomeas, red and white, resembling jasmín; the red, the white, the variegated convolvuluses never looked more lovely, especially the jalap, a gay dandy, who had entirely sunk all acquaintance with calomel and scammony; of the twenty-seven varieties of roses, the King's Acre and the gloire de Dijon do the best; of the geraniums, the scarlet single and Tom Thumb are most hardy, but will only live five years, compared to twenty at home; likewise the fuchsia lives only ten instead of thirty years. From March to September the young tender plants are sent with the greatest benefit to the Hills, but, just as with men, the changes of climate do not universally benefit the old, indeed, may do harm. Dwelling too long on a congenial theme, although neither oaks, bays, or laurels are here, time and space will not permit even to enumerate the treasures of Saharanpore; so let us hurry on along the avenues, just glancing at acacias, cypresses, palms, yuccas, tamarinds, teak, chestnut, mahogany, india-rubber, the logwood for diarrhoea, croton for constipation, eucalyptus globulus with camphor-smelling leaves—the antidote for malaria if it would only grow where required, so far a matter of impossibility that even

the specimens here so carefully tended are but poor. One tree cuts like under-done beef—I forget the name and also the specimen in the spacious museum, there being no catalogue. Thousands of dried plants in paper, fossils of fish, flesh, fowl, and probably of medical practitioners, discovered in the Sewaliks, just as in the museum at Roorkee, elsewhere described; specimens of henbane, attees, kamela, curious fir-cones, shells found in kunkur, also rock crystal, green and blue malachite, asbestos, and that curious sandstone which bends and gives like india-rubber; but it was a sin to pore over old bones in stone when the sweetly-scented flowers of all colours were arrayed in review order, the smartest outside, awaiting inspection. Sir John Lubbock should have been here. The creepers are very grand. A water-lily-like, feathery jasmín, the *Valans Indica*, is curiously beautiful. There are forty acres of Rhæa running to waste until the great secret is discovered how to separate the glutinous matter. There are scented flowers, leaves, and shrubs, also vegetables, besides an experimental farm, worth visiting. The natives, wonderful herbalists, know a great deal more than we give them credit for on this as on other subjects, and on certain days they troop in to worship certain flowers—the *Jasminum mogrum*, a special favourite. The sacred monkeys, to kill which would be sacrilege, give constant trouble, grubbing up seeds, rooting up plants out of mischievous curiosity. Dr. Jameson knew all these tall trees when they were that high, when babies, in fact, were absent; but Mr. Nesbit most kindly acted as cicerone. The water comes in minute arteries from the canal, without creating fever amongst the 200 native gardeners supervised by Europeans. Since draining has been properly done by Mr. Howe, who is surveying Meerut to-day, the station of Saharanpore has become wonderfully healthy, and the clever native doctor at the dispensary told me that the type of fever was far milder—quotidian, quartan ague, bronchitis, pneumonia, dysentery, tape-worm, syphilis the fashionable ailments. Drs. Garden and Smith appear to be great lithotomists, the calculi of fair size, mostly urates. Near the railway station are new quarters, occupied by fifteen families; also, at a little distance, by thirty bachelors, employed as engine-drivers, guards, and what not, who drink water from the wells without filtration, and are innocent of the earth system, the collected excreta of the day carted off and buried—these quarters somewhat resembling those for married soldiers in England, very commodious, are rented at 12s. a room per month. They buy food in the bazaar, excepting bread, baked at Meerut, and the general appearance of the little community is healthy in the extreme. A strong, hearty, jovial engine-driver, smoking a churchwarden, invited me into his neat abode, where his pleasant, buxom wife, and five neat plump—yes, plump little girls, appeared very comfortable. The editor does not hold himself identified with the views expressed by contributors all the world over, so I merely tell you what the engine-driver told me: for instance, that constant employment was the secret of health; sometimes fourteen hours on duty, no regular meals, he, a six months' teetotaler, could go 130 miles without food, calculating eight hours to the 100 miles, and during the famine pressure men had earned £30 a month by working overtime. Blazing sun, hot winds, dust-worms, drenching rains he did not mind; the early cold of the morning tries the strongest. A man who drinks is found out—discharged, which literally means starvation, *ergo*, he remains sober, saving health, pocket, and position. There are inducements to invest, opportunities of leave—seldom cared for, the work very simple, single lines, occasionally accidents through stupid pointamen, the stoppages at stations in May and June very oppressive compared to the relief of rushing through the burning air. No muscular fatigue, no idle hours, aggregation in barracks, loitering about, guards, sentries, or bazaar lounging—no comparison can be made with the soldier's existence. The worthy driver, fifteen years in India, swears by the country, the wife is never dull, and the children, barring whooping-cough, have done well, their

education the difficulty. Engine-driving under a blazing Indian sun can scarcely be termed occupation for women, so we trust the five little girls will eventually marry to make other engine-drivers, guards, and railway officials, generally comfortable in that little nest called home.

Before laying down the pen and paying a third visit to the crowded hospital, just a word about causes affecting fever. Place a long barrack on the flat plain of sand and clay where gradually canals have stopped the natural drainage, raised the water-level, constituting a water-logged district; to the right, at some distance, place a native grave-yard; to the left, the plain, a sheet of water after the rains; near one end of the barrack, a bazaar, a tank—a swamp at certain seasons, the cuts in the earth leading to the regular drain, passing through phases of miniature canals, then mud, which will gradually dry in the sun; at the other end of the barrack, at some distance, place tabies, native lines, tanks again, and beyond these, at a fair distance, the filth-pits. The south-east wind, of all others, will blow pestilent vapours, and should the barrack have single verandahs, and be divided into partitions not permitting free perfilation of air along and across, the want of ventilation will tell at certain seasons when the men have been enfeebled by previous heat. My idea of a model barrack is single storey, raised, flagged floor, thatched roof, double verandahs, or even temporary supplementary verandahs of thick mud and straw, ventilators beyond the men's reach. There are myriads of other points for consideration, for instance, for the first three years every thing should be sacrificed to the acclimatization of the men, who, ignorant of the country, language, customs, dangers, should be placed near other troops, to learn their ways, instead of being detached or at a distance, there blundering and being imposed upon by natives. Officers may have to live at a distance, and the old responsible non-commissioned officers are in their married quarters, whilst the barracks are in charge of the younger ones, equally bewildered with the youngest recruit. There are thousands of things to learn at every hour of the day, and gradually, if the climate be always considered as affected by drainage, air, food, water supply, clothing, duties, the weakly lads may grow into splendid soldiers, such as are met with amongst the acclimatized men at Meerut, some careful, others tough old customers—thirsty souls. Epidemics may pass on unless they are welcomed, or the physician may, Canute fashion, be splashed by the waves. As said before, we are gradually getting to know all about India, every department bent on improvements, oft retarded by climatic influences. Medical men have professional joys and professional sorrows, always praying for the time when in their hands there may be good success.

## Hospital Reports.

### CASES OF CHRONIC MERCURIAL POISONING FROM THE USE OF PINK AND RED VULCANITE IN ARTIFICIAL GUMS, WITH REMARKS AND EXPERIMENTS.

By W. BATHURST WOODMAN, M.D.,

Assistant-Physician to the London Hospital.

As the red sulphide of mercury is one of the oldest preparations of that metal, as it is extensively used in the arts, and has been employed in medicine from a very remote antiquity, it is not surprising that its poisonous properties have long been familiar to medical men. My own attention was drawn to the subject by the actual occurrence of cases in patients coming under my care some ten or twelve years ago. I could find no other explanation of their symptoms, except that they were wearing artificial

gums, or artificial palates coloured with vermilion. I had never then heard that the same facts have been noticed by others, and the experiments then undertaken, and since repeated, were made in complete ignorance of the labours of others on the same subject. In the last edition of Dr. Taylor's great work on "Medical Jurisprudence," vol. i., p. 290, he states, under the heading of "Cinnabar Vermilion—Persulphide of Mercury," that Dr. Sutro published a case in the *Medical Times*, September 27, 1845, p. 17, of poisoning by the vapour of vermilion applied externally.

"A woman, by the advice of a quack, applied the vapour to a cancerous breast. She employed three drachms of vermilion, and covered herself with a sheet, so that the vapour should only reach the body externally. After three fumigations she suffered from severe salivation, and violent fever, which continued for four weeks. The right arm became œdematous." A few lines above, he says: "It (cinnabar) is also improperly applied by some dentists as a colouring matter to vulcanised rubber for mounting artificial teeth. Although this insoluble compound of mercury cannot be regarded as an active irritant poison in the stomach, the placing of it in such a situation that it should always be in contact with the mucous fluids of the mouth is liable to lead to the usual consequences of chronic poisoning by mercury.

In May 1864, a medical man consulted me under the following circumstances: Upon the recommendation of a dentist, he had worn this red composition as a frame for false teeth in place of gold. After some time he perceived a metallic taste in his mouth, the gums became inflamed and ulcerated, there was great weakness and want of nervous power, with pains in the loins, and an eruption on the legs. When the composition was removed, these symptoms abated. [The italics are mine.—W. B. W.] I examined the substance, and found in it a great quantity of vermilion; it had been mixed with the sulphur and rubber to give the appearance of the red colour of the gums.

Dr. Wells, of Reading, has directed the attention of professional men to accidents of this nature. A patient of his who had been provided with a frame of this description for the upper and lower jaws, perceived, soon after wearing it, a metallic taste in his mouth; his health failed, he lost his appetite, and became emaciated; he suffered from flatulency, foetid breath, and looseness of the bowels; his pulse was 100, and weak, and his tongue coated with a white film. This gentleman was peculiarly sensitive to the action of mercury. He left off wearing the teeth, and became gradually better and stronger." (*British Medical Journal*, September 5th, 1863, p. 366).

Dr. Taylor goes on to state that vermilion, or the organic compounds containing it, may be entirely decomposed by nitro-hydrochloric acid. The residue, evaporated to dryness, contains corrosive sublimate. This may be treated with water, ether, &c., and the usual tests applied.

It might almost be inferred from Dr. Taylor's statements that only dentists of an inferior class use or recommend these natural-tinted rubbers, or vulcanite, and that the basis, thus tinted, was always the same. I found, however, on inquiring carefully, that very large quantities of this material were manufactured, and that in past years at least, dentists of the highest respectability, and in various parts of this kingdom, as well as on the Continent, had supplied their patients with this *matériel vraisemblant*. It is not always vulcanite. I had specimens of various depths of tint, from varying proportions of vermilion; and of varying hardness, some of the cheaper kinds being simply blanched gutta-percha incorporated with cinnabar. I have to thank Dr. Martin G. Payne, F.C.S., for several specimens obtained by him for me, others were given me by friends, and some I bought. The result of my examination and experiments is as follows:—

1st. All the pink and red artificial gums, palates, and materials for the same which have been examined by me contained vermilion. It is well to state this, as several dentists have questioned the fact, and others seemed surprised. Some of my medical and chemical friends have

suggested that preparations of lead, chromium, and other pigments would probably be found in some. I can only say no such specimens have yet reached me.

2nd. The quantity of vermilion present was not always proportionate to the depth of tint. Some of the most beautiful and natural specimens contained the pigment rather in a state of very fine division than in any great quantity.

3rd. Does the warmth of the mouth, and the action of the saliva, or of articles of food, actually produce volatilisation or solution of the pigment? As the temperature of the mouth seldom exceeds 37° or 38° centigrade, and saliva is a very dilute solution of the saline substances it contains, the possibility of both these methods of possible injury has been questioned. I believe, however, that poisoning occurs in both ways, and possibly by a third method—viz., by conveyance to the stomach, along with the food ingested, of minute particles worn off in the process of mastication. As regards the first method, or volatilisation, I have satisfied myself by delicate methods of analysis that nearly all the mercurial compounds are somewhat volatile at lower temperatures than 98° or 100° Fahr.

It may be remarked parenthetically that lead, arsenic, and numerous other bodies, in forms not usually deemed volatile, are so in a slight degree, as proved by continuous observation at ordinary temperatures, a fact well-known to chemists. But the prepared rubber, or tinted vulcanite, slowly gives up its mercury (which is only mechanically mixed with it), both to saliva and to an artificial solution made to imitate it with common salt, sulpho-cyanide of potassium, &c., at 60° Fahr., and more quickly if the solution be kept at 100° Fahr., and the metal can be easily detected by electrolysis, as well as by other tests. This solution may be hastened by agitation. Solutions of several of the haloid salts have similar solvent properties. If any one repeats my experiments, he must be content to keep the saliva or other fluid in contact with the rubber for several days. To test for the cinnabar, if our object be to rapidly prove the presence of the metallic pigment, the rubber or vulcanite should be finely sliced, put into nitromuriatic acid with a little distilled water, and exposed to the heat of a sand or water bath.

4th. It will probably be objected, that although this solution goes on slowly, yet the constant washing of the artificial gum or palate would really prevent the occurrence of mischief in the human body. As this is simply a theoretical objection, it seems best answered by narrating three or four out of about a dozen cases observed by me from the year 1862 up to last year, 1873. As in the cases quoted by Dr. Taylor, it will be seen that, once rid of the corpus delicti, the red gum, not of Australia nor of the nursery, but of the dentists, the patients rapidly recovered. "*Tollitur effectus, sublatâ causâ.*"

5th. It is to be noted that the saliva and urine in some of these cases contained minute but unmistakable traces of mercury, every possible precaution being taken to avoid known and probable sources of fallacy.

CASE I.—*Ptyalism, Rupoid Eruptions, Cancroid Sores of the Mouth, and Mercurial Erythism in a Patient of the Torbay Infirmary.*—In the year 1862, a poor woman, living in Torre, æt. 50, consulted me on the state of her mouth. She was profusely salivated; the few teeth she had left were all loosened; there were sores of a deep, ragged, and spongy character in the cheek and gums, like cancrum oris; her breath was extremely fetid, and she had rupoid sores on the body, a general condition of fever, muscular weakness, and general irritability. There was also diarrhoea of a dysenteric kind. In her case there had been previous symptoms of constitutional syphilis, and as she had been under quasi-medical treatment, I suspected that she had been purposely salivated. Indeed, I did not know that she was then wearing a plate of red vulcanite, because she always took it out before coming to see me, and indeed, could not wear it when she first came. It was only when similar symptoms recurred some twice or at intervals of six weeks or two months after recovery,

that I began to suspect some chronic and perennial source of mercurial poisoning, and at last discovered the fact of her wearing a vulcanite gum, supporting seven or eight teeth, which had been given her by some charitable ladies, on account of her speech being so defective. This gum, when examined, proved to contain a very large admixture of red sulphide of mercury. This case had, however, almost escaped my memory when case No. 2 occurred.

CASE II.—*Mercurial Eczema and Erythism in a previously healthy Woman.*—Mrs. F— came to the London Hospital in 1864, and was seen by me during the holiday of one of the assistant-physicians. Unfortunately, I have omitted in my notes to state whose case this really was. She presented a most typical, but pitiable picture, of almost general eczema, of the kind generally known as rubrum. Where there was as yet no discharge, there was intense redness of the skin, and minute papules. Her age was about 40; the catamenia regular. Her general health had been good, in fact, till about three months before, she "had never known a day's illness." Now her condition was sad in the extreme; there were muscular tremors, swollen and ulcerated gums, the breath extremely fetid, and profuse salivation. She was feverish, excitable, and owing to want of sleep, the irritation of the skin, and perhaps some special toxic effect, her mental condition closely bordered upon insanity. Those who have watched cases of poisoning by the methyl compounds of mercury will know why I make this special reservation as to peculiar toxic effects upon the cerebrum. She was wearing a plate of red gum with some five or six teeth in the front of the mouth, to replace the incisors, &c., of the upper set, which she had lost from accident many years before. Asked how long it was since she had been quite well, she replied, "Not since I had my new teeth." This was simply a chronological method, as she had not the least idea of the "plate" being the cause of her symptoms. This "gum" was longer than usual, in fact, it fitted nearly the whole of the roof of the mouth, presenting some four or five square inches of surface at the least. This time, however, it attracted no suspicion. Its use was left off for a time, simply because the mouth was so bad. Admitted to the hospital, she soon got well, with baths, gargles, chlorate of potash, and soothing local treatment. About six weeks after she relapsed into a condition nearly as bad as her former one. This time the resemblance of her symptoms to mercurial poisoning attracted more attention, as the most careful inquiry failed to show any other possible source of poisoning than the "teeth-plate" in question. She had taken no medicine—used no doubtful cosmetics—been exposed to no danger from any manufacture. In short, no reasonable doubt could be entertained as to the cause being some mercurial, for mercury was detected in her saliva, and also in the urine passed by her. The plate was then examined, and found to contain vermilion in large quantity.

It may appear strange that after these two cases, both of which were cured, I believe permanently, by leaving off the use of their new teeth, my attention should not have been more directed to this source of danger. The explanation is simple. Hundreds of people were wearing these plates, and the peculiar symptoms were noted only in one or two. Mercury enters so largely also into popular pharmacy that one often suspected "vegetable" or "antibilious" pills, rather than a cause much nearer home. In the year 1867, two or three similar cases came under my notice in Hampshire, and I could not fail to be struck with the fact that all were wearing these red or pink gums, and that in all the cases there was a sort of chronological sequence between the acquisition of the new teeth and the occurrence of the symptoms. In 1868 and 1869, one or two other cases occurred, but I cannot say that any one of them, taken singly, would have carried conviction to my mind. I know of no special character of "mercurial" foster, and eminent surgeons whom I

have consulted agree with me, that except from other symptoms, from the history of the case, or from discovering mercury in the saliva, urine, or other secretions, there is no pathognomonic character in either mercurial salivation or its factor. Yet my attention was now aroused. I began to collect "red gum material," to make experiments, and to look out for cases. It was not long before one occurred amongst my own acquaintance.

CASE III.—*Salivation, Diarrhœa, &c., in an Aged Lady.*—I was consulted for some apparently anomalous symptoms occurring in an old lady previously of wonderful health and vigour, although closely approaching her 80th year. The house in which she lived was well-built, on high ground, in a healthy situation, and careful inquiry failed to discover anything in her mode of life, or her surroundings, or her past history, to throw light upon her symptoms. She had become irritable, feverish, wakeful at night, tremulous, weak, and utterly prostrate, without any obvious cause. Yet her intellectual faculties were clear enough. There was no kidney disease—no evidences of arterial lesions—no known cause for the mental perturbation or bodily malaise. At the same time, she began to be salivated, to have a coppery taste in the mouth, her palate and gums got sore, there was troublesome diarrhœa, and other unpleasant symptoms. On examination I found she was wearing a large plate of pink vulcanite with teeth imbedded in it, these teeth being of a very good artificial compound, chiefly consisting of silica. The symptoms were at once relieved, and lastly cured, by leaving off this plate and getting a gold one instead. She now enjoys excellent health, considering the advanced age she has reached.

Some still more striking cases presented themselves in the years 1870-1-2, two of which, at the risk of being thought tedious, I will relate.

CASE IV.—*Hydrargyria in a Young and previously Healthy Woman.*—M. P—, æt. 18, was brought to me suffering from ulcerated mouth, salivation, tremor of the limbs, hysterical symptoms, and a sort of lichen-eczema, not so unlike grocers' itch except for its brighter colour and more intense character. She had been a fine healthy girl, quite regular, quite free from nervousness or hysteria, and came of a healthy stock. When quite a child, a drunken man had knocked out some of her front teeth, and for this she had lately been persuaded to wear some artificial ones in a frame of red vulcanite. I examined her mouth, got her to save a considerable quantity of saliva (some three to four pints nearly were rapidly and easily collected), and I tested this and her urine, and in both found sufficient mercury to "silver" a sovereign. She was ordered to leave off the plate, to keep the mouth clean with a weak solution of Condy's fluid; a little zinc ointment was used for the eruption, and no medicine given. She also rapidly got well.

The next case was in a man of about 36, and is, if anything, still more convincing.

CASE V.—*Symptoms of Poisoning by Mercury cured more than once by leaving off the Vulcanite Gum, and recurring again when the Teeth were resumed.*—A literary man was brought to me by one of my medical friends, who had heard me speak of the use of these plates. The patient had some years before suffered from symptoms of syphilis, and my friend thought it possible that our patient had been quacking himself. The symptoms were chiefly confined to the mouth, except the nervous phenomena, which closely approached those of hysteria. He was married, and we could not discover any sexual or alcoholic excesses. His mental labour was not excessive, and he had a private income, which kept him from any special anxiety as to money matters. He had been wearing a red vulcanite plate in the lower jaw for about seven months. The symptoms commenced about five or six weeks after this had been fitted. He admitted that he often slept with the plate in his mouth. We agreed not to tell him our suspicions, but to treat the local symptoms, advising him not to wear the teeth till the mouth

grew harder—indeed, at this time he could not bear it in the mouth. *Mercury was found in the urine.* We did not examine his saliva at the time for obvious reasons. He soon got well, was allowed to resume his teeth, and in six weeks was again ill in the same way, though not so badly. Treated as before. On once more resuming the plate (six months after first attack), he was again salivated, had ulcers in the mouth, &c. This time the saliva was found to contain mercury, when a sufficient quantity had been collected. Once more the red gum was left off, and once more he got well. The nature of the case was then explained to him; but he was so incredulous as to our statement, and so full of confidence in his dentist, who was a personal friend of his, that he began again to wear the plate. Three weeks after he told me triumphantly that he was all right; but ere another three weeks slight symptoms had set in, which gradually became more severe; he was attacked with a species of writer's cramp in his right hand, and then he was persuaded to finally abandon the treacherous teeth—or rather, their setting. He has had a gilt metal frame, and has ever since been perfectly well.

Résumé.—I think few candid persons will doubt that in some cases, perhaps more numerous than we now think, severe effects follow the continued use of artificial gums, palates, and teeth-plates coloured with mercurial pigment. The amalgams used by some dentists may produce similar symptoms. The question is one which I think well deserves the attention of scientific dentists and chemists. I write on it as a practical physician; and as my cases extend over nearly twelve years, I do not think I have displayed undue haste in doing so. There is some danger now of arsenical, lead, and chromium pigments being substituted, and toxic symptoms, due to these metals rather than to mercury, may possibly have been noticed in some cases. A dental student told me that herpes labialis is unusually common in those who wear false teeth; but this may possibly be due to mechanical irritation only. Well-fitting teeth are otherwise so desirable, that it would be well to devise and employ some pigment of a natural colour which should be free from the objections attaching to all the metals I have named.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 9, 1874.

THE ACTION OF DRUGS.

V.

IN our second article on this subject we called attention to the fact, that while three-quarters of a grain of extract of Calabar bean was given as the minimum fatal dose for a rabbit weighing 3 lbs., and 20 grains as the minimum fatal dose of sulphate of atropia, yet Professor Bennett gave only three to four and a half grains of the atropia to

antagonise three-quarters of a grain of extract of Calabar bean (Experiments 152-154), and we now give the following extract from the *British Medical Journal*, from the pen of Dr. W. A. Richards, of Winchester, as bearing on this point:—

"The general conclusion of the committee is, that 'the sulphate of atropia does antagonise fatal doses of Calabar bean, but within a very limited area,' and 'that it certainly prolongs life.'

"Now the point to which I wish to call attention is this: the Calabar bean, in these experiments, is given in a dose twice or three times as large as the minimum fatal dose; indeed, in a quantity which proves fatal in a few minutes. But the amount of sulphate of atropia administered to counteract this overwhelming dose of Calabar bean is in no case sufficiently large, when given by itself, to affect the pupil or to produce any symptoms whatever. In almost all the cases, it is only one-sixth or one-eighth part of the dose at which the Committee states that any symptoms of the administration of atropia begin. Ought we, therefore, to expect that such a dose, so totally inadequate to produce the slightest symptom when given by itself, would have any very marked effect on an animal already under the influence of a quantity of another poison sufficient to destroy it in a few minutes? Let us take the second set of experiments, which are the best arranged and most conclusive, and what do we find? Of the first seven rabbits, to which the Calabar bean was given by itself, six died in less than ten minutes each, the seventh in sixteen minutes. But, in the remaining seven, where the same quantity of Calabar bean was followed by one-half grain to one grain and a quarter of sulphate of atropia, life was prolonged in the several cases from 29 minutes to 110 minutes. Thus we find that a quantity of sulphate of atropia, far too small to produce any physiological symptoms when given by itself, yet, given to an animal under the influence of a rapidly fatal dose of Calabar bean, causes it to live from four to ten times as long as it otherwise would. From this, the conclusion would naturally be, that the antagonism between the two drugs was almost marvellously striking; and the apparently obvious lesson that it would suggest would be to increase the quantity of sulphate of atropia given to from three-quarters of a grain to ten grains, fifteen grains, twenty grains, or more; so that it should bear a reasonable physiological proportion to the quantity of Calabar bean given. This, however, does not seem to have been done; and the question to which, through your assistance, I am endeavouring to get an answer is—Why was it not done? Because, as the report stands, the almost homœopathic character of the doses of sulphate of atropia compared to the doses of Calabar bean given seems to explain the results arrived at. Thus the report states that the 'so-called antagonism existed within very narrow limits. The danger was not death by too great a dose of sulphate of atropia, the supposed antagonist, but death from the effects of Calabar bean. In this respect, there was also a marked contrast to the action of hydrate of chloral on the physiological effects of strychnia. In the latter instance the danger evidently would be, in a case of poisoning by strychnia, to give too large a dose of hydrate of chloral; whereas, in the case of poisoning by extract of Calabar bean, it would apparently be very difficult to arrest its effects, because a small dose of the latter produces little effect (at all events in rabbits), and the effects of Calabar bean are so violent as soon to destroy life.' Now the report gives the minimum fatal dose of hydrate of chloral as exactly the same as the minimum fatal dose of sulphate of atropia—viz., twenty-one grains in each case; and the doses of strychnia and of extract of Calabar bean to be counteracted in the two cases are also of much the same relative strength—that is, compared with the minimum fatal dose of each. But the quantities of hydrate of chloral and of sulphate of atropia used to counteract them respectively are extremely different. About fifteen grains or sixteen grains is the ordinary dose of hydrate of chloral

used as an antidote to strychnia, whilst three-quarters of a grain is the ordinary dose of sulphate of atropia used as an antidote to Calabar bean in the experiments of the Committee. That is to say, in the first case, doses verging on the minimum fatal dose of the drug are constantly given; in the second, a sufficient dose to produce any physiological symptoms whatever is never once given, although the poisonous effect to be counteracted in the two cases is of the same strength. It is in order to obtain an explanation of this difficulty, which seems to mar an elaborate, beautiful, and valuable series of experiments, that I have troubled you at this length."

This discrepancy requires explanation, for the question is—Did the experimenters give small doses of atropia to antagonise fatal doses of extract of Calabar bean *because they knew atropia in small doses acts as a stimulant to the heart?* and did they avoid giving large doses in these cases *because atropia in large doses diminishes the force and activity of the heart?* They do not say so, although they conclude from their experiments that "when the proportion of atropia was increased, death was hastened in proportion;" and again, we have pointed out that all the experiments (see *MEDICAL PRESS*, p. 422) would seem to indicate that where the atropia was given to antagonise Calabar bean in larger doses than three-quarters of a grain, *death was hastened than when smaller doses were given.* (Italics ours.)

Thus we see this dual action of a drug is well worthy of investigation, both in antagonising the effect of another drug and in the treatment of disease. The following, which we give below, and which appeared in the *British Medical Journal* of Nov. 14th, from the pen of Dr. T. Lauder Brunton, is also worthy of note, for he says that 1-100th of a grain of sulphate of atropia should be employed to antagonise the effects of muscarine. (Now, Dr. Tanner gives 1-50th of a grain as the medicinal dose.) Thus we see again the small dose used as a restorative because it stimulates the action of the heart; for Dr. Harley found that 1-60th of a grain raised the pulse from between twenty to sixty beats; while 1-20th of a grain lowered the pulse from 110 to 98, diminishing it in volume and power (a). We desire to call especial notice to this subject, as we trust that future experimenters will be more careful in noting the varying effects of different doses, and that thus our knowledge of the range of action of drugs may be placed on a firmer basis, and that we may eventually know more of a drug than that it is simply a "sedative," "stimulant," "purgative," or "diuretic," for we are only "just beginning to realise the fact that our knowledge of therapeutics is very limited; and we hail with pleasure all experimenters who are endeavouring to increase our knowledge of this most important branch of our profession.

We now pass on to the next report, in which Professor Bennett calls attention to the following conclusions, arrived at by Dr. John Harley, and contrasts them with those arrived at by the American experimenters:—

"Conclusions.—1. In the dog, belladonna, when administered simultaneously with opium, more or less completely prevents nausea and vomiting; and, when given previously, entirely prevents these effects. 2. Whether given previously, simultaneously, or subsequently, atropia completely counteracts the respiratory restraint on the free action of the heart, which is so prominent an effect of the operation of opium. We can wish for no more.

(a) "Vegetable Neurotics," pages 203-206.

perfect an illustration of the beneficial influence of a medicine under suitable conditions than that afforded by the simple and direct action of atropia in relieving the impending syncope which often persists for many hours after a dose of opium. At first, the cardiac systoles are doubled, but a regular expiratory pause remains. During the next sixty or ninety seconds, the systoles become stronger and each one distinctly perceptible to the finger; and at the end of this time the inspiratory intermissions cease, and no trace of their presence remains. The effect is even more marked under the influence of the combined action of morphia and thebaia. 3. While the special effects of opium on the muscles of organic life are thus counteracted by the stimulant action of atropia on the sympathetic, the cerebral and anæsthetic effects are intensified and prolonged by belladonna, and hypnosis is converted into narcosis. 4. On the other hand, all the effects of atropia, excepting perhaps the influence on the heart, are increased and prolonged by opium, and the cerebral effect in particular; the insomnia which results from excessive doses is converted into narcotism, or a mixture of narcotism and delirium. 5. The simultaneous action of opium retards the evacuation of urine, but in no degree interferes with the elimination of atropia by the kidneys."

"Conclusions.—1. That the evidence of antagonism in any given case is inconclusive. 2. Taken individually or collectively, the cases show that belladonna has no influence whatever in accelerating the recovery from the poisonous effects of opium. 3. That somnolency, stupor, narcotism, and coma—the essential effects of the action of opium—are both intensified and prolonged by the concurrent action of belladonna. 4. That belladonna is powerless to obviate the chief danger in opium-poisoning—viz., the depression of the respiratory function. 5. That the results of the combined action of opium and belladonna are the same, whether given in medicinal or toxic doses. While, therefore, belladonna cannot in any sense be regarded as an antidote against opium, but in large doses the exact reverse, it may, under certain conditions mentioned below, and always in very small doses, be used in conjunction with other remedies as a means of aiding the recovery. [The 'conditions' to which Dr. Harley alludes are, to give '1-96th of a grain of sulphate of atropia at intervals of two hours, to stimulate the failing power of the heart.]"

The following are the conclusions arrived at by Mitchell, Keen, and Morehouse:—

"The foregoing experiments and observations authorise us, we think, to draw the following conclusions as to the use of hypodermic injections, and as to the antagonism of atropia and morphia.

"1. Conia, atropia, and daturia, have no power to lessen pain when used subdermally.

"2. Morphia thus used is of the utmost value to relieve pain, and is most potent, in certain forms of neuralgia, the nearer it is applied to the seat of the suffering.

"3. Morphia lowers the pulse slightly, or not at all. Atropia usually lowers the pulse a few beats within ten minutes, and then raises it twenty to fifty beats within an hour. The pulse finally falls about the tenth hour below the normal number, and regains its healthy rate within twenty-four hours.

"4. Morphia has no power to prevent atropia from thus influencing the pulse; so that, as regards the circulation, they do not counteract one another.

"5. During the change of the pulse under atropia, the number of respirations is hardly altered at all.

"6. As regards the eye, the two agents in question are mutually antagonistic; but atropia continues to act for a much longer time than morphia.

"7. The cerebral symptoms caused by either drug are to a great extent capable of being overcome by the other; but, owing to the different rates at which they move to affect the system, it is not easy to obtain a perfect balance of effects; and this was made the more difficult from the

fact already mentioned, that atropia has the greater duration of toxic activity.

"8. The dry mouth of atropia is not made less by the coincident or precedent use of morphia. Atropia does not constipate, and may even relax, the bowels; morphia has a reverse tendency.

"9. The nausea of morphia is not antagonised or prevented by atropia.

"10. Both agents cause dysuria in certain cases, nor is the dysuria occasioned by the one agent relieved by the other.

"11. Atropia has no ability to alter or lessen the energy with which morphia acts to diminish sensibility or relieve the pain of neuralgic disease.

"12. As regards toxic effects on the cerebral organs, the two agents are mutually antidotal; but this antagonism does not prevail throughout the whole range of their influence, so that, in some respects, they do not counteract one another; whilst, as regards one organ—the bladder—both seem to affect it in a similar way."

To test these conclusions the Committee make various experiments with sulphate of atropia and meconate of morphia on dogs, first ascertaining that the normal respirations of a dog per minute are about 30, and the cardiac pulsations about 120. They then proceed to inject into a Scotch terrier weighing 12 lbs. two grains of meconate of morphia, dissolved in twenty-eight minims of water, with the following results: depression of the cardiac impulses, from 120 to 72 per minute, and of the respiratory movements, from 30 to 14 per minute. Then, forty minutes after the commencement of the experiment, the cardiac pulsations became so feeble that they could not be counted with accuracy. The respiratory movements were deep and prolonged. The animal was deeply narcotised. Reflex movements were made on touching the eyelashes or the conjunctiva, but there were none on pinching the legs or tail. Fæces were passed involuntarily. There was very little moisture about the mouth. There were slight jerks occasionally of the muscles of the back. The dog continued in this state for four hours, when it began slowly to recover. It recovered entirely. For twenty-four hours it appeared to be feeble in its hinder limbs. Three days afterwards it was quite lively. The dose was nearly, but not quite, a fatal one. Nobody seeing the dog three hours after it had received the two grains of meconate of morphia would have believed in its recovery.

Thus we see that morphia lowers the cardiac impulses and respiratory movements, as stated by Dr. Harley ("Vegetable Neurotics," pages 107-114), and is thus opposed to the statement No. 3 of the American physicians, who say "that morphia lowers the pulse slightly, or not at all." So far the evidence is in favour of Dr. Harley's conclusions.

## THE NEW CHARTER OF THE IRISH COLLEGE OF PHYSICIANS.

OUR readers are already aware, through the columns of the MEDICAL PRESS AND CIRCULAR, that an application on behalf of the Irish College of Physicians for an amended charter was before Parliament last session, and that certain returns referring to the application were called for by Mr. Dunbar. The demand for a new charter has evoked from five of the most noted members of the College—viz., Sir Dominic Corrigan, Professor Haughton,

Dr. Lyons, Dr. Sinclair, and Dr. Cruise—a formidable and forcible protest, which will, no doubt, influence powerfully the decision of the Crown as to the granting of the demand of the College. The memorialists undertake to show that in any new charter to be granted to the College it is undesirable—

1. That the power of election by ballot of Fellows and officers should be granted to the College.
2. That a new grade of members should be instituted without consulting the wishes and interest of the Licentiates as well as those of the Fellows.

In support of the first proposition they object to the use of the ballot because the College, in voting, is exercising a public trust for which it should be responsible to public opinion and to the profession for the due and fair exercise of its powers, and they quote the opinion of the Lord Chief Justice of the Queen's Bench, expressed at the visitation of 1870: "Could it be said to be for the benefit of a learned institution that if any of these gentlemen [Plunkett, Cheyne, Percival, and Graves] happened to be a candidate, he was to be shuffled out of his election by a vote given in the dark?"

From the foundation of the College in 1692 to 1828, a period of upwards of 130 years, there was open voting, and the records of the College do not show that any evil whatever resulted from it. In 1828 the College assumed the power of voting by ballot, and within a few years after that date, and through a subsequent period of forty-eight years, men have been rejected who we assert should not have been black-beaned or excluded by secret voting. "We do not," say the memorialists, "give names, but we are prepared to give them if required."

They moreover characterise the plea that it is desirable that the voting should be secret as a most unworthy motive, and it overlooks the important contrast that while the Fellow would protect himself under the shield of secret voting, the candidate, however worthy, is exposed to have his reputation stabbed in the dark by personal pique, professional jealousy, or religious animosity.

The College consists at present of fifty-five Fellows.

On only one occasion—viz. St. Luke's day, 18th October, when election to offices of trust and emolument to the amount of £1,500 per annum takes place, did the number rise to thirty-three. There were twenty-eight other business meetings in the year, and the average attendance was only fifteen. "It is," they say, "obvious that with so small a body of Fellows and such small attendances the power of election by ballot could be controlled by a very small number, and could be diverted to any purpose."

In 1862, "An Act, 25 Vic., c. 18, to define the powers of the President and Fellows of the King and Queen's College of Physicians in Ireland with respect to the election of Fellows," was passed, which removed restrictions on admission to the College; but the College in the same year passed a bye-law declaring that one black bean in five should exclude, so as to neutralise as far as possible the opening of the College. The rejection of five candidates in succession led to an appeal to the visitors.

Notwithstanding a strong condemnatory expression on the part of the visitors, the majority of the College were still determined to baffle, if possible, the liberalising spirit of the Legislature; they passed the following obstructive bye-law restricting the enlargement of the College:—

"New Bye-law.—Any enlargement of the number of

Fellows shall only be made in pursuance of a resolution passed at three consecutive business meetings, held in each year previous to the 1st July; and every such resolution shall express the number of Fellows which it is expedient to elect on the next ensuing St. Luke's Day."

"We hope," say the memorialists, "we have now advanced facts sufficient to show that election by ballot should not be granted."

Having thus disposed of the ballot question the memorialists address themselves to the second proposal of the draft charter to which they object, viz.:—"That it shall be lawful for the Fellows to institute a grade in the said college (other than that of Fellows or Licentiates), to be styled members, to be elected in such manner, and under such regulations as to collegiate rights, privileges, qualifications, examinations, and payment, as the college may direct."

"This, the memorialists say would confer on the Fellows the power to make any regulations they might think proper, a power that we think ought not to be entrusted to any corporate body."

To the institution of the new grade they object, "on behalf of upwards of 1,200 licentiates of the college, whose fees constitute the chief income of the corporation, and who are not represented upon it. A question so deeply involving the interests of the licentiates should not be dealt with behind their backs, by a small body, and one in which they have no voice."

The memorialists express the view that the creation of this new class would have the effect of indefinitely reducing the prospect of a licentiate obtaining the Fellowship "and thus deprive him of his chance of being elected to any of the offices of emolument in the patronage of the college, for in practice they are usually bestowed only on Fellows."

In conclusion, they state their deliberate conviction that the creation of an intermediate order would tend still further to restrict the number of the corporation, "and to perpetuate the monopoly of offices in the possession of a small handful of Fellows, which has characterised the history of the college in times past, and which at present greatly diminishes the influence and prestige which a body constituted like the King and Queen's College of Physicians was intended to exercise in this country."

The entire protest, emanating as it does from five of the best known and most influential Fellows of the College, and phrased in such unmistakable terms, cannot fail to command attention and respect, and we cannot deny to it our most cordial adhesion and approval. It seems to have been completely forgotten by the Fellows, and for half a century never to have been thought of, that the King and Queen's College of Physicians in Ireland is, or ought to be, something else than a club, and it is well that the injudicious attempt to confirm the illegal practices of the last fifty years has evoked an expression of opinion which may serve to remind them that a great licensing corporation is not always to be managed as a quiet family party.

The power of a few to bar the entrance of new comers into their conclave is perfectly comprehensible and defensible in a social community where every man is entitled to select his associates with regard solely to his own feelings. But such a power is entirely out of place in the administration of a Qualifying Body where no consideration but the advantage of the profession and of the College should enter into the calculation. We venture to predict that no Government will acquiesce in making law of such a system as has existed in the College during the memory of our generation, and we are unmistakably of opinion that the perpetuation of such a system would be disastrous both to the College and to the interests of medicine in Ireland.

## Notes on Current Topics.

### Degrees in State Medicine.

As we have already announced, the question of conferring degrees in Public Health is before the University of London. We hope before this great and growing University adds another to its medical degrees that the propriety of doing so will be studied in all its aspects. The degrees of this University are sufficiently difficult to attain, and we think that the M.B. Lond., considering he has been examined in all the subjects, may fairly consider himself eligible for a medical officership of health without any additional certificate. At this moment the post is open to every registered practitioner, and we hope it may continue to be so. The graduates of the London University take the very highest rank amongst practitioners, and as the new degree would only confer on their own graduates, we cannot see what they have to gain by its institution.

### Faults in the Law for Regulation of Lunatic Asylums in Ireland.

It appears from the observations of the inspectors that the 5th and 6th Vic., cap. 123, by which alone private asylums are regulated in Ireland, is not so comprehensive in its provisions as could be desired. In regard to the right of detention, save in the case of lunatics under the Court of Chancery, none is authorised against common law. Hence the owner of a private asylum is liable at any moment to an action for false imprisonment in this country, on the plea of harbouring a paid-for lunatic, however marked his malady. Indeed, the same principle, if it be one, holds good in our public institutions for the insane, if the party detained is not deposed to as being absolutely dangerous to himself or others. The anomaly was sustained in a trial here, when an acknowledged maniac obtained substantial damages against the governors of the Richmond District Asylum, at a trial in the Court of Queen's Bench.

Again, there is no provision in Ireland as in England for allowing convalescents out on a temporary probation, to be protected during its continuance from incidental consequences. Nothing is occasionally more practically useful than such an opportunity to test the mind prior to absolute freedom being accorded. Neither in case of an escape is there a legal power of capture or recovery. The inspectors say:—"These deficiencies, from the result of experience, we should wish to see remedied, and especially on behalf of the insane themselves, and the protection of property. It appears to us most desirable that in certain doubtful cases the inspectors should have power to allow convalescents abroad, under cautious restrictions in each case, and after a personal examination, to verify cures."

### Complications of Gonorrhœa.

DR. DOMINIQUE CALVO (*France Méd.*, No. 92) recommends the application of fifteen or twenty leeches at the commencement of epidymitis to the groin, and the testicles to be wrapped in linseed-meal poultices. Rest in bed is requisite, and every two days a purge of Seidlitz powders. Later on, three times daily, he recommends rubbing with

3 grammes of mercurial ointment and 6 grammes of extract of belladonna. If there are pains of acute character, he recommends punctures with the lancet. When the inflammation has disappeared and there remains only engorgement, he recommends friction with 6 grammes of extract of belladonna, 4 grammes of iodide of potassium, and 30 of purified lard, and also emplastrum vigo cum mercurio to envelope the scrotum.

### Hydatid Cyst.

DR. GALLARD (*France Méd.*, No. 92) mentions the case of a patient who died in his wards from the effects of a supposed hydatid cyst of the liver. Recamier's method of puncture was employed, and afterwards Dieulafoy's method, with negative result in both cases. The patient succumbed.

### Diseases of Newly-born Infants.

DR. PARROT (*Le Progrès Méd.*, No. 47) says that thrush in infants sometimes communicates cracked nipples to nurses, and even may give the nurse thrush of the nipple by contagion, and the nurse may reinfect another infant.

### Dr. Dujardin-Beaumetz on Therapeutics.

On commencing a course of lectures in the *Ecole Pratique* of Paris, recently, the above gentleman says, "The physician who overwhelms his patient with drugs is very often in reality the poorest physician." He observed that the useless plants and compositions should be put out of the codex, and only the really active substances retained.

### Jaborandi.

M. ALBERT ROBIN, in the *Société de Biologie* (*Le Progrès Méd.*, No. 47), communicated the effects of jaborandi on animals and patients seen in the wards of Dr. Gubler. One of the first symptoms, remarked in some five minutes after taking the drug, was exaggerated lachrymal secretion, then salivation and abundant sweating. The secretions are also made more active in the stomach, the bronchial tubes and trachea, and nasal fossæ, the secretion of the intestines being increased so as to cause diarrhœa. The temperature in man is increased immediately before the sweating period. In patients with articular rheumatism such phenomena are noticed; and on the morrow lowering of the temperature may be seen. Gubler on this account recommends jaborandi in articular rheumatism, when there is no heart disease, since it causes palpitation. It is of service in cases of bronchitis and of albuminuria.

### The Comparative Success of Lunacy Treatment in Ireland.

It appears from the latest Parliamentary Report that, so far, then, as the important objects for which Irish district asylums have been established are to be judged of by statistics, but above all by their affording a refuge to our fellow-creatures as places of judicious treatment and safety, as well as the indirect but certain benefits accruing to society at large, by checking, as far as human means can, the propagation of mental disease, so hereditary in its character, their working during the year 1873 has been satisfactory and successful.

The recoveries during the year 1873 amounted to

1,031—547 males and 487 females—or nearly 11 per cent. upon the total—9,417—under treatment during the twelvemonth. The aggregate deaths in the same period were 665. The mortality—or 7·10 per cent. on the entire number in asylums, and for the most part among the aged and infirm—is under the general average elsewhere.

Analysed according to the usual mode, the recoveries during the past twelve months in Irish public asylums would realise 45 per cent., and the improvements, as represented by discharged patients, 3, between both fully 58 per cent. on admissions.

The inspectors attribute much of this success to the improved method of treating lunatics which has recently been adopted in these institutions. They express an opinion that—

“There is probably no single deficiency more detrimental to the well-being of the insane, be they in public or private establishments, than want of occupation. A listless and apathetic existence, tending to encourage delusions, will often frustrate the best directed efforts of science.

“The arrangements for employing and amusing patients are not quite adequate in some district asylums, although there ought to be no great difficulty in devising means to carry out such desirable objects to their full extent, for the special circumstances of each institution will probably suggest the best means for carrying out the principle referred to. Boards of Governors will find, even from an economic point of view, that they will best consult the interests of the institution committed to their care by the moderate outlay the adoption of these suggestions would involve. The cost would be more than repaid by a reduction of the period patients might otherwise remain under treatment.”

#### Remedy for Dysmenorrhœa.

DR. EDIS recommends in some cases a suppository of half a grain of morphia with one-seventh of a grain of atropine inserted at bed time in dysmenorrhœa. This, he says, will often allay the most severe pain, and enable the patient to procure sleep, when otherwise she would have passed the night in agony, the stomach itself refusing to absorb anodyne mixtures, rejecting them as soon as swallowed, and thus cutting the patient off from the ordinary means of relief. In other cases of dysmenorrhœa he recommends an enema of water as hot as the patient can conveniently bear, combined or not with half a drachm of laudanum.

#### Pathological Society.

AT the Pathological Society of London, Nov. 3, 1874, Mr. Warren Tay showed two children with alopecia areata and trichophyton tonsurans. The children had bald patches, whilst the hairs in the neighbourhood were the subject of bulbous atrophy. In these cases the trichophyton was found along with the bald spots. Dr. Tilbury Fox would not affirm that circumscribed baldness might not be produced by a fungus. Sir William Jenner held that the baldness was due to atrophy of the hair bulbs, and that this atrophied condition favoured parasitic growth. The fungus grew readily, and where was there a more favourable nidus than an atrophied hair bulb? Mr. Hilton Fagge had never met with a case of true alopecia areata due to a parasitic growth.

Dr. Dowse described a case of aneurism of the pulmonary artery which occurred in a girl, æt. 19, who was pregnant. There was enlarged cardiac dulness and systolic murmur over the pulmonary artery, but death took place from pericarditis. The pericardium was covered with lymph and contained blood, coming from a rent in a globular tumour, of the size of a pullet's egg, at the root of the pulmonary artery, which was filled by a firm clot. There were vegetations in the pulmonary valves, and enlargement of the right ventricle, with tricuspid regurgitation.

Dr. Cayley showed a specimen of syphilitic disease of the heart from a man who died in bed after taking a dose of chloral, to which he was accustomed. The heart was enlarged, and contained in its structure several fibroid nodules, which were seen microscopically to consist of fibro-nucleated tissue and small round cells.

#### The Antagonism of Remedies.

IT appears from the Report of the Committee of the British Medical Association to investigate the Antagonism of Remedies, that the minimum fatal dose of theine for a cat weighing nearly five pounds was  $5\frac{1}{2}$  grains. The minimum fatal dose of meconate of morphia was found to be for a cat from  $1\frac{1}{2}$  to  $1\frac{3}{4}$  grains. Theine was not found to be an antagonist to the poison of morphia, except that convulsions were prevented, but death ensued. The meconate of morphia does not act on rabbits at all in the same way as it does upon cats. Epileptiform attacks are caused in rabbits by the salts of morphia, and theine produces similar results. The physiological action of theine and caffeine are so similar as to make it impossible to distinguish these substances from one another. Six grains of caffeine produced in a cat weighing 5 lbs. intense excitement, convulsion, and death in two and a quarter hours. The antagonism of caffeine to morphia in cats was also limited, although apparent. Guararine given in doses of 4 grains to a cat weighing 5 lbs. 1 oz. did not prevent death of the animal, which took place in two hours, after much excitement, after the subcutaneous injection of 1 grain of meconate of morphia.

#### A Cambridge Certificate in State Medicine.

IT has been publicly announced in the daily papers that the Board of Medical Studies has recommended the Senate of the University of Cambridge to institute a Certificate in State Medicine, and it is actually proposed that any registered practitioner should be eligible for examination. This is one of the most liberal proposals that have emanated from this liberal board, and if we are to have special certificates at all, it is most desirable that they should be thus freely conferred on all who are willing to submit to an examination. The subjects of examination are to be as follows:—

1. Physics and chemistry: the principles of chemistry and methods of analysis, with especial reference to analyses of air and water; the laws of heat and the principles of pneumatics; hydrostatics and hydraulics, with especial reference to ventilation; water-supply, drainage, construction of dwellings, and sanitary engineering in general.
2. Laws relating to public health.
3. Sanitary statistics.
4. Origin, prevention, pathology, and propagation of epidemic diseases; effects of over-crowding, vitiated

air, impure water, and bad and insufficient food; unhealthy occupations, and the diseases to which they give rise; water-supply and disposal of sewage and refuse; nuisance injurious to health; distribution of diseases within the United Kingdom, and effects of soil, season, and climate. The fee for the examination is to be four guineas.

### The Development of the Irish Lunacy System.

A COMPARISON of the arrangements for the care and custody of lunatics as it existed twenty-four years ago, and as it now exists, is drawn by the inspectors in their report, and is both interesting and instructive. We adverted to the growth and extension of asylums in Ireland, from the period when the department, limited to ten public asylums, containing 2,300 patients, was transferred as a separate branch of the public service to the undivided charge of the inspectors of lunatics. We have now reached a date in its development, when irrespective of the Central Criminal Asylum, and of other institutions, such as union workhouses, in which persons mentally affected and subject to our visitations are largely to be found, district asylums, containing 7,400 inmates, have increased in number to twenty-two, and private houses to twenty-one. The total outlay already entailed in the construction and establishment generally of district asylums may be estimated at about a million and a quarter. The cost of their support and maintenance last year amounted to £186,400.

### The Opium Crop.

THE *Philadelphia Reporter* says that the crop of this year now averages from 4000 to 6000 baskets or cases. Of this quantity the United States require above 2000 cases. The price has risen lately, averaging £1 per pound. Fifteen years ago it averaged 15s. per pound. Owing to the late high prices, some persons at Smyrna have during the last two years adulterated the pure drug by mixing it with spurious matter, and passing it off as first quality. They succeeded in selling about 300 cases during the last two years; but as the fraud has been discovered, the consequence has been that purchasers have been very careful from whom they obtain this drug. The crop for 1874, which is collected in May and June, has suffered considerably from the late severe frosts; consequently a short yield will also increase the value. In 1873 the stock existing in Smyrna was 1500 baskets; in London, 700; and in the United States, 600 baskets.

### The late Dr. Edward Smith, F.R.S.

THIS gentleman's official career was alone sufficient to entitle him to the respect of the profession and the public; but he had done other work of even greater importance, and some of his original investigations were models that many might well imitate. His researches on the effects of exertion on the breathing and the pulse, and those on the action of alcohol and other agents, deserve the highest commendation. His work on "Health" is well known, and another on "Food" forms one of the International Series brought out by Messrs. King and Co., and he also only recently published one of the best manuals for medical

officers of health and inspectors of nuisances. We cannot help regretting that his death should have been made the occasion of reviving an old controversy, between him and the editor of a contemporary the only object of which appears to be to depreciate the dead because he did not always agree with the editor in question.

### Anæsthesia by the Simultaneous Employment of Chloral and Chloroform.

DR. LAUNELONGUE (*France Médicale*, No. 93) read before the Société de Chirurgie of Paris some experiments of M. Fornet, who proposes to attain anæsthesia in two divisions. In the first period opium or morphia is given, and chloroform in the second. M. Fornet prefers chloral to opium, either by the mouth or rectum.

In the case of a child aged five years, two grammes of chloral were given: the patient fell off to sleep, and during sleep chloroform was administered.

In the second case a man, aged twenty-five, who had failed to be anæsthetised by chloroform, had five grammes of chloral, and in an hour and a half fell asleep, when chloroform was given and the operation performed.

M. Fornet observes that there is an immense difference between giving chloroform when the patient is awake and when he is asleep. When the patient is awake a large dose of chloroform is needed, hence the danger of poisoning.

Dr. Dolbeau, on the contrary, said that chance had proved to him the danger of giving chloroform after chloral—a lady who used to take syrup of chloral to alleviate the pain of fissure of the rectum—and the patient on being given chloroform was nearly dying from the effects of the combination. In two other cases dangerous symptoms supervened, and one of them proved fatal.

M. Guyon spoke in confirmation of M. Dolbeau's remarks.

M. Démarquay had seen in animals a great tendency to chilliness after the use of chloral and chloroform successively.

M. Perrin corroborated the observations of M. Fornet. He had given three grammes of chloral, and then chloroform, with good results.

Dr. Dolbeau's cases were those of great doses.

### Exophthalmic Goitre.

DR. TEREOL brought a man, aged forty-one, before the Société Médicale des Hôpitaux with the threefold characters of exophthalmic goitre. The goitre was unilateral (*France Méd.*, No. 92), on the right; there was no pulsation in it, and it had slightly diminished in volume through the influence of tincture of iodine. The exophthalmos was double and slight. There were palpitations of the heart, not perceived by the patient: the goitre arose in 1874. There were derangements of sensation and mobility, more marked on the right side. There was diplopia, vertigo, and hyperalgesia, with exaggerated reflex movements. He asked whether this was not goitre complicated with cerebral tumour, or sclerosis, or softening. He had put the patient under hydropathic treatment, iron, and digitalis; but the latter caused vomiting and was discontinued. He intended to try electricity.

Dr. Dujardin-Beaumetz thought that the patient had two diseases—exophthalmic goitre, and perhaps also dis-

ease of the cord. Was there no chance of there being also diabetes?

Dr. Tereol said there was no diabetes. In 1874 the goitre appeared; in January, 1874, vertigo; and in June, vomiting.

Dr. Herard was not surprised that the patient had never noticed his palpitations, for he had seen patients with 160 and 170 pulsations per minute not perceive them. Hydro-pathic treatment had succeeded best with him, and digitalis was of no use.

Dr. Gros said iodine sometimes was useful, without doing any damage, and iron and hydropathy were useful.

Dr. Potain had seen diabetes and albuminuria in a patient with exophthalmic goitre.

### Accommodation for the Irish Insane and Prevalence of Lunacy.

THE Inspector's Report, which has just reached us, contains the following comparative summary of the registered and unregistered insane for the year 1873, contrasted with the number recorded in last Parliamentary returns:

	1872.	1873.
In public asylums . . . . .	7,140	1,347
In private do. . . . .	647	664
In gaols . . . . .	—	—
In poorhouses . . . . .	2,966	3,130
In Lucan, supported by Government	30	25
In Central Asylum for Criminal Lunatics . . . . .	175	160
Total number of registered insane	10,958	11,326
Insane at large . . . . .	7,219	6,881
Total in Ireland . . . . .	18,177	18,307

The above table indicates an increase of registered lunatics at the close of 1873, but it will be also seen from it that the excess in the accommodated is in part met by a diminution in the mentally affected at large.

We assume that a like ratio to the population has been maintained as in 1873, as among the sane and the insane, the total number of the latter in 1871 being 18,327, or about three in each thousand of the population; in 1872 it was 18,177, and in 1873, 18,303.

Under these circumstances, and looking to the fluctuations in the amount of the inhabitants of different localities. The inspectors believe that lunacy is not only not on the increase since 1871 in Ireland, but that when old and chronic patients now in asylums and elsewhere, who, eight-and-twenty years ago constituted a portion of the percentages of the population of Ireland when it was nearly 2,000,000 greater than at present, shall have died off, a certain decrease is likely to result in the absolute number of our insane; while in England the advance within the same period of three years, in those "reputed to be of unsound mind," was 3,387, or from 58,640 to 62,027.

### Professor Lister and the Antiseptic Method.

A CORRESPONDENT of the *Progrès Medical* (No. 47), writing from Edinburgh, in November last, speaks of the Royal Infirmary with its 500 beds, where the surgical wards are quite separate from the medical. Mr. Lister, says the writer, admits the ideas of Pasteur without reserve,

and repudiates all ideas of spontaneous generation, and is a partisan of the vital theory of fermentation. He believes that wounds exposed to the air may be contaminated by atmospheric germs, bacteria, and other organisms therein contained, and to prevent them we must try to prevent the entrance of the germs.

In entering Mr. Lister's wards, which contain usually not more than five or six beds, we are struck with the strong smell of carbolic acid. The assistants plunge their hands when dressing the wound in solution of carbolic acid. The wound is washed with a solution of one-tenth of carbolic acid, and all instruments used are dipped in the carbolic solution.

Eight layers of gauze dipped in the carbolic solution are placed over the end of the stump to be dressed, and between the seventh layer and the eighth a very thin layer of india-rubber is placed. The whole apparatus is fixed with bands of gauze which have been dipped in the following mixture:—Carbolic acid, one part; resin, five parts; paraffin, seven parts. The resin is employed on account of the tenacity with which it retains the carbolic acid, and the paraffin is added to give a suitable consistence.

Mr. Lister gives the greatest care to his cases, and passes many hours a day in his wards.

### The Employment of Eschmarch's Elastic Compression as a Means of obtaining Local Anæsthesia.

DR. CHAUVEL read in the *Société de Chirurgie (France Méd., No. 92)* a paper on this point, in which, after taking the normal sensibility of the part, and then applying the elastic compression for some time, he again tried what the sensibility was. In only one case was the patient refractory; in all the rest a diminution of sensibility was remarked. The anæsthesia produced requires fifteen to twenty minutes to bring it about, and it appears more marked in the upper than in the lower extremity. The anæsthesia is almost always incomplete. Analgesia is the most marked feature. The sensation of contact remains longer.

In the wards experiments were made with three cases of toe-nail grown in. In the first case, the elastic ligature having been applied, the surgeon cut and tore away a piece of nail of six millimetres in breadth. The patient said there was very little pain. In the second experiment the remains of the nail were removed without much pain; and then Vienna paste was applied for twelve minutes to the matrix without causing pain.

M. Le Fort having employed the method of elastic compression, had been struck with the diminution of the sensibility in the compressed limb, but had never witnessed complete insensibility.

### Metropolitan Asylums Board.

At a fully-attended meeting of the managers of the Metropolitan District Asylums on Saturday last, the presentation of the report as to the state of the Homerton Hospital led to a long discussion. It stated that the committee had felt it their duty to annex the report of the medical officer, from which it would be seen that there had been 73 admissions, 59 discharges, and 16 deaths, leaving 210 patients under treatment. The minimum accommo-

dation, as the managers were aware, was fixed at 102, but most of the cases brought being children, the committee had ventured to authorise the superintendent to increase the number of beds to the same extent as was done at the height of the late small-pox epidemic—viz., 140. Should, however, the admissions continue at the present rate, the committee feared they would not be able to meet the requirements of the district for more than a fortnight longer; and should this happen to be the case application must be made to the Stockwell committee for accommodation, the pressure there not appearing so great.

The report as to the overcrowding of the Homerton Hospital formed an argument to show the necessity for the erection of another hospital for the accommodation of patients suffering from fever, small-pox, or other infectious diseases, and the danger was pointed out of there being no receptacles should an epidemic of small-pox or fever break out.

The report from the Stockwell Hospital committee stated that during the past fortnight there had been received 34 cases, that there had been 6 deaths and 50 discharges, leaving 111 under treatment, as against 140 at the last meeting. In the small-pox hospital 12 patients had been admitted, 2 had been discharged, and 1 had died, leaving at present 11 under treatment.

The report of the Leavesden committee stated that during the past fortnight there had been received six patients, seven had died, and one discharged, leaving 1,802 at present in the asylum.

Reference was made as to the introduction of small-pox into London by means of emigrant ships, and the necessary precautions were decided upon.

### Small-pox Inoculation in Ireland.

At the Castlebar Petty Sessions, last week, an old man named John Prendergast was charged with attempting to inoculate the children of Edward Jeffers, at Curraun, co. Mayo. The prisoner was charged under "32 Vic., chap. 87, sec. 4," which gives the magistrates summary jurisdiction to order imprisonment for periods up to six months.

Mr. Fitzgerald said the practice of inoculation had been going on in his district to a great extent, and there had been several deaths from the pernicious practice. This was not, he knew, the defendant's first offence either.

The information of the constable was read. He arrested the prisoner, and on his person he found two lancets, and when he came in sight of him he endeavoured to hide in the ground a paper parcel, which, on being opened, was found to contain "matter." The prisoner informed the Bench that he had not used the lancets for a number of years back. Edward Jeffers said that when the prisoner made the proposition to him to inoculate his children he sent for the police. The prisoner returned a few days afterwards and renewed the proposition. The Bench, after a private consultation, remanded the prisoner for eight days, for the opinion of the law adviser, and the evidence of Dr. Knott, to whom the "matter" was to be handed over in the meantime.

It would seem that the magistrates were in doubt whether they could convict without evidence that the lymph found on the prisoner was variolous. In the present case, we imagine, the proof of the fact that he proposed in-

oculation ought to be sufficient to establish his guilt, even if no lymph or lancets had been found in his possession; but the case introduces a new consideration, as to how it would be possible to ascertain without doubt whether lymph found on a prisoner was variolous or vaccinnous. Probably the microscope would afford unchallengable testimony on the subject.

### Typhoid Fever and the Water-Supply at Lewes.

THE Local Government Board sitting at Whitehall will scarcely wait until the town of Lewes has been decimated by fever before taking the necessary steps to put a stop to the further supply of water containing the specific typhoid fever germs to the inhabitants. A water company supplying water seriously contaminated by sewage ought to be made amenable to the adulteration laws, and the officer of health should be empowered to deal with a dangerous form of adulteration with a high hand. The directors of the water company at Lewes, by all accounts, seem to think the poisoning of 450 of their customers of less importance than that of securing "a good dividend."

The Rev. W. S. Edwards, writing as a sufferer in his family, by partaking of a poisonous dose of the Lewes fever water, scarcely feels inclined to ascribe the disease to "an accidental and temporary pollution of the water." It appears that "during the dry season of last July, the vile sewage water was pumped into the pipes from a neighbouring stream, and from that time the town became a hospital—husbands, wives, and children were struck down and homes filled with mourning. We have little hope of any better management for the future. Not a single word of sympathy for the 450 sufferers has been uttered; and with a strange callousness the chairman of the Waterworks Company coolly said, 'Although one of their first duties might be to endeavour to get a good dividend for their shareholders, yet the directors of the Lewes Water Company did not feel that to be the only object they had in view;' 'the directors were prepared to incur any reasonable expense to supply the town,' &c. As to a constant supply, which is declared to be indispensable, the chairman further added, 'If it could be done consistently with anything like a reasonable remuneration, he was sure the directors would be prepared to recommend it.' It has since transpired that the constant service is exceedingly doubtful, and in the meantime, fresh cases of fever almost daily occur in the town of Lewes."

### Soldiers' Cottages at Woolwich.

WE hear that diphtheria has been prevalent in the soldiers' cottages on Woolwich Common, and that many children have died of the disease.

### Killed and Wounded in the War of 1870.

DR. CHENU reports that during the Franco-German war, the French lost 138,871 men by wounds or disease. This includes 2,818 officers. The Germans lost 40,741.

It has been determined to establish a Hospital for Incurables in Glasgow, and another in Edinburgh, and a considerable sum of money has already been promised for the purpose.

### Drunkenness as a Cause of Insanity.

A FORCIBLE but disheartening opinion upon the effect of drink upon the prevalence of lunacy in Ireland is expressed by the inspectors of Irish lunatic asylums in their last report. They express their opinion that indulgence in the use of ardent spirits, and unfortunately of the most deleterious quality, is becoming more prevalent from day to day in the country, instigating its victims to the wildest acts of violence and depravity—maddening, without actual delusions, and terminating for the most part in epilepsy, or disease of the brain, but not in genuine lunacy.

Melancholy, however, as may be the immediate consequences of drunkenness to those unceasingly addicted to it, the results are occasionally far more deplorable in regard to the offspring of inebriate parents, who are born imbecile, idiotic, mutes, or malformed, as the inspectors have known to be the case in two, or even three, members of the same family.

### New Examples of Tubercular Lesions in the Spinal Cord.

DR. LIVUVILLE, Chief of the Laboratory of the Cliniques at the Hôtel-Dieu (*Progrès Méd.* No. 47), showed recently a spinal cord, in the cervical region of which existed a large tubercle, yellowish in colour, rather resistant in character, and which occupied the grey substance to the extent of about an almond in size. This was found in a young man aged 26, who had generalised tuberculosis, with symptoms of meningo-myelitis. The myelitis was shown by paraplegic symptoms and eschars on the sacrum. The autopsy made 15th April, 1874, showed miliary tubercles in the lungs, with small cavities. Liver was fatty degenerated.

Tubercles were found in the cerebral membranes and brain in the form of miliary granulations, along the vessels and also in the cerebellum.

In the spinal cord a medullary arachnoiditis was noticed, very intense in character, especially posteriorly, in the middle third of the cervico-dorsal region. This was characterised by very numerous fine and recent adhesions. The pia mater was thickened, whitish, wrinkled, and quite hid the cord itself. There was fluid in the arachnoid cavity, and the pia mater was in places as if imbibed with a kind of turbid, thickish serosity.

The venous trunks in the neighbourhood were enlarged and varicose. Below the brachial enlargement of the cord there was remarked a certain augmentation in volume of the cord, but there was no clear hardness perceptible. On section there was found a tumour occupying almost the whole of the cord, in the grey substance. It was yellowish in colour.

### Affections of the Tongue.

At the Medical Microscopical Society, on November 20th, Dr. Goodhart read a paper on "Ichthyosis Linguae." He had seen the disease in two cases, both men over fifty, with history of syphilis. It was characterised by hard white elevated patches on the tongue, and more rarely on the cheeks, like warty excrescences, consisting of numerous vertically set papillae covered by thickened epithelium. The underlying cutis vera and subcutaneous tissues were also hypertrophied. The muscular tissue of the tongue was

not affected. At present, the disease was incurable. Mr. Jabez Hogg preferred the term tylosis linguae to that of ichthyosis. Mr. Fairlie Clarke had seen thinning of the papillae from pressure of the epithelium. Cancer supervened, either from growth of epithelium from above or below, as the result of irritation of the patch of ichthyosis.

### Dissemination of Literature in America.

AUTHORS and publishers, medical and non-medical, are aware that of late years a very large demand has existed on the part of American houses for English books, the remainders of whole editions of which are sometimes taken off the hands of medical writers at reduced prices to make way for new editions. It may not be uninteresting, therefore, to quote some facts stated in *The Bookseller* as to the enormous development of the trade in what are called "subscription" books at the other side of the Atlantic. Every one is acquainted with the class of book-pedlars who pay us an occasional visit, and "palaver" us into taking monthly numbers of a "History of the War," or some work of the sort which we don't want, and for which we shall eventually pay about twice the shop price. It is this canvassing system which may be said now to supply the American provinces with literature. There is a very large class of people who, without being positively illiterate, have no inclination to enter a book-store, even if there happen to be one in the neighbourhood, which is not always the case. They are wealthy enough to buy books, but would never think of doing so unless the agent presented the book to their notice, accompanied by a glib account of its useful or amusing qualities. The people to whom I allude, while possessing little culture, are very far from being ignorant, in the ordinary acceptation of the term. They would never think of buying a book, any more than a chromo or a patent needle-threader, unless it was brought to their notice; and then, if the agent knows how to interest them, they will buy the one as readily as the other. To assist and protect his agent, the publisher will use his best efforts to prevent his books getting into the hands of the regular trade, and it is only by the most ingenious artifices that booksellers can obtain a scanty supply of subscription books. A large firm will sometimes have as many as five hundred canvassers employed directly or indirectly in selling its books. Ten thousand copies of a book in the subscription trade is considered a very moderate sale indeed; and a book must generally reach a sale of twenty thousand to be considered a success. A book entitled "Nurse and Spy," giving the experiences of an army nurse, caught the popular fancy, and 185,000 copies were sold within eighteen months. It would be hard to get more than two cents a pound for the book to-day. The following is a list of some of the most successful books published in Hartford within the past ten or twelve years: Mark Twain's, "Innocents Abroad," 150,000; "Roughing It," 110,000; "The Gilded Age," 58,000; "Beyond the Mississippi," 150,000; "Field, Dungeon, and Escape," 105,000; "The Great Rebellion," by J. F. Headley, 150,000; "Bible History," 95,000; Dr. W. Smith's "Dictionary of the Bible," 100,000; Parson's "Laws of Business," 125,000; "Sunshine and Shadow," by Matthew Hale Smith, 100,000; Lossing's "History of the Civil

War," and "History of the United States," both in several volumes, continue to sell at the rate of nearly 20,000 volumes a year.

### The Scarletina in Ireland.

THE returns for the last two weeks made by the Registrar-General are evidently unreliable, and they manifest the want of punctuality, which unfortunately characterises the Irish registration system, and must continue to characterise it as long as so great a quantity of avoidable clerk-work is imposed upon the medical registrar at an utterly insufficient remuneration. According to the returns, the mortality from scarlatina, which we reported a fortnight since as having only slightly increased in Dublin, but as having alarmingly advanced in Belfast, had last week risen to a high ratio in Dublin, but fallen much lower in the north. The Dublin mortality of that week was 29, or 11 more than the previous week, while the Belfast deaths numbered 32, or 20 less than shown in the previous return. It is evident that the weekly returns do not ever approximately represent the actual mortality.

The returns of the present week lead us to hope for an actual decline in the epidemic, for we observe that in Dublin the deaths are down to 19, while those in Belfast, 36—about the same as were recorded in the previous return.

THE Royal Society reopened on Nov. 30.

YELLOW fever is in its most virulent form at Charleston, U.S.

SMALL-POX has broken out in Jamaica, and quarantine has already been declared.

ACCORDING to the *Daily Telegraph*, typhus has broken out in the garrison of Spandau.

SIR RANALD MARTIN has just died at a ripe old age, full of honours and surrounded by friends.

SOME cases of puerperal fever have occurred at Leicester, said to have been propagated by a nurse.

THERE has been an outbreak of small-pox in Vienna, the victims being chiefly children of an early age.

SMALL-POX has broken out at Rugby, and a temporary hospital is to be immediately erected.

DR. FAYRER, F.R.C.P., has been appointed to succeed the late Sir R. Martin at the Indian Medical Board.

DR. P. W. LATHAM has been elected Downing Professor of Medicine at the University of Cambridge.

DR. HARRIS has resigned his office at St. Bartholomew's Hospital. Dr. Hollis is a candidate for the vacant Assistant-Physiciancy.

AN examination of candidates for twenty appointments as surgeon in Her Majesty's Indian Medical Service will be held in London in February, 1875.

LIFE-LIKE photographs have been published by Messrs. Fradelle and Marshall of the late Dr. Edward Smith, F.R.S., and of the late Dr. Lankester, F.R.S.

THE time-worn old "Dreadnought," which was the home of so many sufferers as the Hospital Ship, opposite Greenwich Hospital, has been sent to Chatham to be broken up.

WE are not surprised to learn that Mr. Forsyth, M.P., Mr. Boord, M.P., Colonel Addison, and Mr. Thicke, have resigned their seats as members of the Hospital Saturday Fund.

THE Paddington Vestry is sending out a circular to the ministers of all the denominations in the parish, urging them to press upon families afflicted with scarlet fever, the propriety of not letting their children continue attending such schools. We have already recorded several similar proposals to curb the progress of the disease.

By the will of the late Miss Ellen Markland, St. Mary's Hospital and the Epileptic Hospital of London each receive £500, the Leicester Infirmary a like amount; the West London Hospital, Brompton Consumption Hospital, Moorfields Ophthalmic Hospital, Medical Benevolent College, Epsom, Hospital for Sick Children, Royal Free Hospital, and the Cancer Hospital, each receive £200.

THE French nation, through two accredited representatives, presented her Majesty, on Thursday last, with four magnificent volumes, of about three feet in thickness, entitled "Homage Nationale." These volumes contain the signatures of the representatives of all sections of the French nation, and are intended to perpetuate their sense of gratitude to the British nation for help rendered to their sick and wounded during the late war. This souvenir, so excellently conceived, and delicately carried out, will be accepted by the nation in the same friendly sympathy that prompted it to minister to the sick and dying in so terrible an emergency.

THE will of the late Professor Wyman, of Boston, which has been duly proved, contains, as stated in the *Boston Medical and Surgical Journal*, some bequests of great interest to the profession. His admirable collection of comparative anatomy is left to the Boston Society of Natural History in consideration of a very moderate sum. Though not very large, this collection is nearly perfect in its way. As an illustration of the anatomy of the vertebrates, it is unequalled in America. It represents the greater part of Prof. Wyman's labours, and will be a perpetual monument to him. On some future occasion we may give some account of its chief features.

The specimens of morbid anatomy and monstrosity are left to the Boston Society for Medical Improvement. The collection of this Society is to be given to the Medical School as soon as the new building is finished.

### Double Aortic Aneurism.

IN the Glasgow Pathological and Clinical Society Mr. H. E. Clark recently showed a case of double aortic aneurism. The upper aneurism, in the ascending part of the arch, was very large, and seemed in process of spontaneous cure, the fibrinous layers being very firm, and fully two inches thick. This aneurism had pushed aside the neighbouring parts without producing any great pressure; the pneumogastric and inferior laryngeal nerves, although in contact with the aneurism, were not imbedded in its walls. The second aneurism, much smaller, involved only the posterior part and right side of the descending aorta, opposite the fourth dorsal vertebra, to which it firmly adhered. An opening of one-eighth of an inch in diameter communicated between the sac and the œsophagus. There was difficulty in swallowing, but no laryngeal symptoms.

### The Surgical Society of Ireland.

THE opening meeting of the Surgical Society of Ireland, which was deferred from the previous week in respect to the memory of the late Dr. Hargrave, who had died a few days before, was held on Friday evening last in the Royal College of Surgeons, and was very largely attended. The inaugural address was delivered by the President of the College, Mr. Tufnell, and was listened to with much interest and attention. Mr. Tufnell reviewed the objects of the Society and its constitution, and referred in eloquent and feeling terms to the death of Dr. Hargrave and Dr. Arthur Jacob, both of whom had been intimately connected with the Society for many years, and with whom he (the President) had been associated as a colleague for nearly a quarter of a century.

At the desire of Dr. Arthur Jacob, expressed just before his last illness, the President presented to the College the original drawings on ivory made for the illustration of Dr. Jacob's communication to the Royal Society on the "Membrana Jacobi" in 1819, and also a number of original drawings of the anatomy of the eye made for the illustration of a subsequent contribution to the Medico-Chirurgical Transactions in 1832.

Mr. Tufnell also presented, on his own behalf, the very primitive and unadorned ink-bottle from which, for a long series of years, Dr. Jacob's pen had written most of his ablest scientific and journalistic publications.

We hope to print the address *in extenso* in our next.

THE Professorship of Midwifery in the Royal College of Surgeons in Ireland has become vacant by the resignation of Dr. Sawyer, and the Council have issued notices for an election of his successor.

Dr. Sawyer succeeded to the Professorship on the resignation of it by the late Dr. Thomas Beatty. The candidates spoken of as likely to seek the Professorship are Dr. Lombe Atthill, Dr. John Cronyn, Dr. Rutherford Kirkpatrick, Dr. William Roe, and Dr. More Madden. Dr. Kidd will not be a candidate.

### Vivisection and the British Medical Association.

THE episode of the last meeting of the British Medical Association which disturbed the equanimity of the vivisectional physiologists so seriously has been made the ground for legal proceedings, which, we very much regret to learn, have been instituted by the Society for the Prevention of Cruelty to Animals against the gentlemen connected with the Physiological Section of the Norwich meeting. It will be recollected that two dogs had been prepared for the purpose of illustrating the effect of injecting certain preparations into the veins, when Mr. Tufnell, the President of the Irish College of Surgeons, and Professor Houghton entered the room. These gentlemen protested against the cruelty of subjecting the dogs to such an experiment, which they declared was entirely unnecessary and commonplace. Something resembling a *mêlée* ensued, during which Mr. Tufnell cut the cord which bound the dogs, and set them at liberty. Afterwards, we believe, the animals were again secured, and the experiments performed. The prosecution set on foot by the Society for Prevention of Cruelty to Animals commenced, we believe, yesterday, and Mr. Tufnell has gone to Norwich on a *subpoena tecum duces* to give his evidence in the case.

## Correspondence.

### HOSPITAL SATURDAY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—With the greatest pain I have read the article "Hospital Saturday" in the MEDICAL PRESS of Nov. 25. When I consider the effect such writing is likely to produce on your readers, I cannot help fearing that an undue prejudice will arise in their minds against the "working man," so severely taken to task for having "conclusively demonstrated their utter meanness of mind and complete lack of humanity." As I am one of that class (the working man), will you allow me to say that scarcely a week elapses without subscriptions being required, *and paid*, for the relief of necessitous wives, children, and widows of our own members. If your readers could spare the time to visit workshops and manufacturing premises—I mean the places in which we absolutely work, not the ante-rooms or counting-houses—they would there see announcements of benefits, invitations for help, and appeals for aid. These appeals are *invariably met and liberally subscribed to*. If it happens (as I have occasionally known) that one person declines to pay his mite, the utter contempt which his "mates" display to him soon convinces him that his "complete lack of humanity" meets its due reward in the sharpness of his comrades' remarks. As I have worked in London (the working men of which city fares so hardly—I had almost said unjustly—at your hands—I am sure unwittingly so) for thirty-four years as a journeyman, I think my experience may count for something; and I unhesitatingly say that a vast amount of money is paid weekly by my fellow-workmen of all trades in charity, properly so-called. That there are amongst us too many, alas! who "spend a comfortable weekly income on skittles, drunkenness, or ruffianly laziness," we are compelled reluctantly to admit. But that the "working-man" as a class is amenable to such a sweeping charge I demur to; witness the numerous benefit societies, sick clubs, provident societies, and other institutions of a similar description, *entirely supported* by our own class. Surely we may ask for more consideration from the medical profession than that meted to us in the article I venture to refer to. Speaking personally, I can but hope that the writer was carried away for the moment by his anger against a totally uncalled for movement, initiated by totally unknown persons, and therefore totally mistrusted. This I venture to assert, that if Hospital Saturday had been set on foot by any of those leaders of the working class who are known and trusted, the result would have been far different. These titles—whether military or naval—are not *alone* sufficient to inspire confidence, unless some other claim than that can be advanced. I fear to trespass on your valuable space by many further remarks, or I could, I believe, say much to alter the impres-

sion I so dread being made on the minds of those who read your CIRCULAR; but would respectfully suggest that a very large proportion of the Sunday collection came immediately from those who are accused of not sparing "even a sixpence a year to keep himself and his family above the pauper herd, or to alleviate the miseries of his destitute fellow-worker." We can afford to pass by the remarks about brawling "republicanism" and talking "patriotism as long as he can get a platform upon which to display his ignorance," &c., as we hope your readers know full well that these charges are somewhat exaggerated, as far as the mass of workmen are concerned: there must necessarily in all classes be offences, but "woe unto those through whom offences come"—and apparently through whom they do *not* come, sometimes. I would not have presumed to address the editor of a medical journal had I not felt that an unjust prejudice might be created in that quarter we so much respect, and feared that no word of remonstrance would have a chance of being heard if I had taken any other means of contesting that which I sincerely believe must have been written under a very pardonable sense of wrong and injustice. Trusting to that universal liberality—so well known and appreciated by the working men themselves—which has ever distinguished the profession in whose interest the MEDICAL PRESS has spoken, I crave the insertion of this very imperfect attempt of mine to remove a well-meant, but unfounded animadversion from a class of whose honour I am jealous, and whose members I, from long association, respect, and even love. Enclosing my name and address,

I am, Sir, very respectfully yours,

H. P. G.

Nov. 26, 1874.

[OUR correspondent will do us the justice to remember that we have spoken of working men in the abstract, and not of the superior class to which his very intelligent and well-phrased letter shows him to belong. Little as is our confidence in either the motives or the judgment of the promoters of the Hospital Saturday movement, we cannot think that its failure was the result of a similar want of confidence on the part of the London "working man." The enthusiasm with which the class of men of whom we speak has from time to time joined in Trafalgar Square demonstrations and Hyde Park revolutions show that there is no lack of "steam" amongst them for the furtherance of much less worthy objects, and at the bidding of much less worthy leaders, than those who had the guidance of the "Hospital Saturday" movement. After all, our correspondent will admit that "benefits, invitations for help, and appeals for aid," which are confined to the working man's own class, are only a narrow-hearted sort of charity, and, in our opinion, little credit for benevolence attaches to the working man for the weekly or monthly subscription which he gives to his trades union, or to the "benefit societies, sick clubs, provident societies, and other institutions of a similar description," which he joins usually for the contingent enjoyment of their advantages by himself.

The facts of the case remain unaltered by any defence of the working man which may be offered. *Imprimis*, it is notorious that the average wages of a skilled London artisan amount, as compared with the necessities of his family, to a handsome independence, at least, sufficient to enable him to secure medical attendance for them in sickness and to spare a little for his poorer neighbour—*Item*.

A day's experience of the out-patient rooms of the London Hospital is sufficient to show that the artisan class habitually quarter themselves, their wives and children upon public charity—*Item*.

The ignominious failure of the Hospital Saturday appeal shows that the artisan class as a whole are ready to take all they

can get for nothing, but not pay even a fraction of a penny per head per annum in real unselfish charity.

Can our correspondent balance the weight of these three facts by quoting a single philanthropic movement originated by working men or carried into effect by their leaders?—Ed. M. P. & C.]

## Medical News.

University of London.—The following are lists of the candidates who passed the recent examinations:—

### B.S. EXAMINATION.

#### First Division.

Duncan, Peter Thomas, University College.  
Gould, Alfred Pearce, University College.

#### Second Division.

Crocker, Henry Radcliffe, University College.  
Houghton, Walter Benoni, University College.  
Pope, Harry Campbell, Liverpool Royal Infirmary and University College.

### M.D. EXAMINATION.

Addy, Boughton, St. Thomas's Hospital.  
Barfoot, George Harry, University College.  
Barlow, Thomas, B.S., B.Sc., University College.  
Bomford, Gerald, King's College.  
Cockburn, John Alexander (*Gold Medal*), King's College.  
Colgate, Henry, B.S., University College.  
Coupland, Sidney, University College, and Middlesex Hospital.  
Dyson, William, B.A., University College.  
Gibbins, Alfred Thomas, King's College.  
\*Greenfield, William Smith, B.S., University College and St. Thomas's Hospital.  
Harris, James Alfred, University of Edinburgh.  
Mackey, Edward, Queen's College, Birmingham.  
\*Skerritt, Edward Markham, B.S., B.A., University College.  
Vachell, Charles Tanfield, King's College.

### LOGIC AND MORAL PHILOSOPHY ONLY.

Buck, Thomas Alpheus, Guy's Hospital.  
Dukes, Clement, B.S., St. Thomas's Hospital.  
Perkins, Charles Edward Steele, Guy's Hospital.  
Yeo, Isaac Burney, King's College.

## NOTICES TO CORRESPONDENTS.

✂ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

### THE CONTAGIOUS DISEASES ACTS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The position of the MEDICAL PRESS AND CIRCULAR on the question of the Contagious Diseases Acts is certainly, as you remark, "more independent and more just than that of the other medical weeklies." There is very much to be said on the side of those who oppose the Acts, and I therefore trust that you will allow me to call the attention of your readers to a few facts for which I am indebted to the Army and Navy Medical Reports.

In the army in the five years from 1861 to 1866 secondary or true syphilis, the only disease which can be considered a matter of State concern, went down without the Acts from 31 to 23 cases of admission to hospital per 1,000 men. In the next five years, from 1866 to 1871, with the Acts, it only went down from 23 to 20, notwithstanding all the efforts made by the administrators to show good results, and in every intervening year it was higher with the Acts than in 1866, the year they were first introduced. In the same periods gonorrhoea went down without the Acts from 111 to 93 cases per 1,000 men, and went up with them from 93 to 105, having also been much higher in the intervening years.

The navy report also shows conclusively that the navy is in a worse condition than it was in 1866, the year when the Acts were first enforced. Thus, in the years from 1862 to 1866, the total admissions to hospital had gone down without the existing Acts from 143 to 80 per

\* Obtained the number of marks qualifying for the Medal.

1,000 men; but since 1867 the number of admissions has gone up without intermission every year, till in 1871 it stood at 101 per 1,000 men. The admissions for gonorrhoea, which went down between 1862 and 1865 from 35 to 20, have gone up since 1866 from 20 to 50 per 1,000 men. The number of admissions for true syphilis was almost identical in 1871 with what it was in 1866, and the number of men constantly sick of venereal affections was so likewise, although from 1862 to 1866, without the Acts, there had been a large diminution of this number.

A very striking fact is the great increase in the number invalided for venereal diseases in the army since the introduction of the Acts in 1866. The year the existing Act was introduced, it was 43; in 1871 it was 81; in the intervening years it touched so high a number as 145. All this shows conclusively that the army and navy were better without the Acts than with them; and the same observation is true also of the women subject to the Acts, for among the registered women disease has increased above 20 per cent., and the deaths are twenty times as many as in the year before the Act enjoining periodical examinations was passed. In fact, Sir, the Contagious Diseases Acts is both a crime and a blunder; it costs £40,000 a year and does not do one pennyworth of good.

Your obedient servant,

CHAS. BELL TAYLOR, M.D., F.R.C.S.E., &c.

Nottingham.

**THE HOSPITAL FUND.**—The *Boston Medical Journal* of the 19th ult. states, "The Hospital Sunday Fund in London amounted to £1,000, which cost £1,100 to collect." Our contemporary will allow us to correct this misstatement. The Hospital Sunday Fund in the places of worship in the metropolis yielded over £30,000, costing but a few hundreds to collect and distribute. The Hospital Saturday Fund (workmen's) yielded £3,800, and cost £1,500 to collect.

**INDIAN MEDICAL SERVICE.**—Notice of an examination for the appointment of surgeons in H.M.'s Indian Service is announced in another column.

DR. J. V. L.—We regret that we cannot extend our Free List by placing your name thereon.

**PATENT MEDICINES.**—"Will you help me out of this mud-hole?" asked one traveller, whose team was stuck in the mud, of another who was passing. "No, I can't stop," said the other. "I would take it as a great favour," said the man in trouble. "What are you loaded with?" asked the traveller. "Patent medicines," was the reply. "I guess I will try to help you out, then, as I am loaded with tombstones." They have been constant companions ever since.—*Philadelphia Medical Times*.

DR. D., of S.—Crowded out for want of space. It will appear in our next.

**COMMUNICATIONS, ENCLOSURES, &c.**, have been received from—Prof. de Aguiar, Lisbon. Dr. Winslow, London. Dr. Ormsby, Dublin. Dr. Labore, Paris. Dr. Lane, Isle of Man. Dr. Pavy, London. Dr. Pearson, Scarborough. Dr. Heaton, Leeds. Dr. Kennedy, Dublin. Dr. Harvey Hilliard, Holloway. Dr. Hime, Sheffield. Dr. Blake, Bloomsbury. Dr. Nicholas, Wandsworth. Dr. James, Camden. Dr. Davys, Swords. Dr. Bartley, Bristol. Dr. Boyd Mushet, New Brighton. Dr. Purdon, Belfast. Mr. Lunn, Edgbaston. Mr. Hutchinson, Rugby. Dr. Hughlings Jackson, London. Dr. Martin, Portlawn. Mr. Goodall, Leeds. Mr. Brown, London. Dr. Borchardt, Manchester. Mr. Towle, Manchester. Mr. Wilson, Westminster Hospital. Dr. Hand-sel Griffiths, Dublin. The Secretary of the Westminster Hospital. Dr. Murdoch, Magherafelt. Dr. Wade, Kilcock. Dr. Usher, Dundrum. Dr. Hamerton, Navan. Dr. Kelly, Mullingar. Dr. Sanderson, Kiltormer. Dr. Carleton, Delvin. Dr. Lynn, Armagh. Dr. Jones, Cork. Dr. Burne, Dublin. Mr. Gale, Bath. Mr. Cooke, Thurles. Dr. O'Connor, Galbally. Dr. Luther, Cappoquin. Dr. Tate, Dublin. Dr. McCarthy, Fethard. Messrs. Fannin and Co., Dublin. Dr. McIlroy, Ballymoney. Dr. Shanley, Athlone. Dr. Reid, Kingstown. Mr. Beatty, Coombe Hospital. Dr. W. Smith, Dublin. Dr. Hanan, Tallow. Dr. Grealy, Lettermore. Dr. Murphy, Croom. Mr. Swingborne, London. Dr. Agar, Ponder's End.

#### MEETINGS OF THE LONDON SOCIETIES.

WEDNESDAY, Dec. 9th.—Epidemiological Society, 8 p.m. Mr. J. Netten Radcliffe, "On Plague." Drs. Dickson, Schlimmel, and Marconi on similar subjects.

Hunterian, 7½ p.m.—Meeting of Council. Eight p.m. Dr. Roper, "On the most advantageous Method of Delivery in Placenta Previa."

FRIDAY, Dec. 11th.—Clinical, 8½ p.m. Mr. Rouse, "On Aneurism." Mr. Venning, "On Syphilis with Secondary Symptoms after Twenty-three Years."

MONDAY, Dec. 14th.—Medical Society, 8 p.m. Ordinary.

TUESDAY, Dec. 15th.—Pathological, 8 p.m. Ordinary.

#### BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

The Philosophy of Voice. By Chas. Lunn. London: Baillière, Tindall, and Cox.

St. Bartholomew's Hospital Reports. Vol. X.

Clinical Pocket-Book. London: Smith, Elder, and Co.

Rational Medicine. Introductory Address by D. Ferrier, M.D. London: Smith, Elder, and Co.

Bolivia. By Avelino Aramayo. London: T. Richards.

The Art and Science of Medicine. Introductory Address by Dr. Dickinson.

Fourth Annual Report of the Vigilance Association.

The Forces which carry on the Circulation of the Blood. By Andrew Buchanan, M.D. London: J. and A. Churchill.

The Middlesex Hospital Reports for 1873.

Journal de Thérapeutique. The Druggist. The Students' Journal.

The Clinic. Philadelphia Medical Reporter. Medical Times. Allgemeine Wiener Medizinische Zeitung. The Obstetrical Journal. The Practitioner. Monthly Microscopical Journal. Guy's Hospital Gazette.

#### VACANCIES.

North-Eastern Hospital for Children, Hackney. House Surgeon. Salary, £100, with furnished apartments, &c. (See Advt.)

Parish of St. James's, Westminster. Medical Officer of Health and Analyst. Salary, £200. Applications to the Vestry Clerk.

Brighthelm Infirmary. House Surgeon. Salary, £100 per annum, with furnished apartments. Applications to the Hon. Sec. before the 8th inst.

Nottingham General Hospital. Physician. Honorary.

Marylebone General Dispensary. Physician. Honorary.

Woolwich Union, Kent. Assistant Medical Officer to the new Infirmary at Plumstead. Salary, £60, with board and residence. Applications, under cover, to the Clerk to the Board.

Ashton-under-Lyne. House Surgeon to District Infirmary. Salary, £80, with board and residence. Applicants must address Mr. Hugh Mason, Ashton.

Poplar Sick Asylum. Dispenser, at 2 guineas per week. Applicants must address the Clerk to the Managers, Brompton, Middlesex.

Gloucester Infirmary. Surgeon and Assistant Surgeon. Both Honorary. Applications to the Secretary.

Farringdon Union, Berks. Medical Officer for the Shrivensham District. Salary, £70 per annum, with fees extra. Applications, under cover, to the Clerk to the Guardians, Farringdon.

#### APPOINTMENTS.

BENHAM, W. T., M.D., M.R.C.S.E., Physician-in-Chief to the Chilean Government Lunatic Asylum at Santiago.

BUCK, W. E., M.B., M.R.C.S.E., Medical Officer of Health for the Oakham Rural Sanitary District.

CLARK, H. E., L.R.C.P.Ed., a Dispensary Surgeon to the Royal Infirmary, Glasgow.

COOK, R., L.R.C.S.Ed., Medical Officer and Public Vaccinator for the Desford District of the Market Bosworth Union.

CROCKER, H. R., M.B., M.R.C.S.E., Resident Medical Officer to the Charing Cross Hospital.

FLINK, D. E., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer for the Lampugh District of the Whitehaven Union.

HARRIS, J. W., M.R.C.S.E., a Consulting Surgeon to the Exeter Dispensary, on resigning as Surgeon.

HUGHES, P. W., L.R.C.P.Ed., L.R.C.S.Ed., House Surgeon to the County and Borough of Carmarthen Infirmary.

LATHAM, P. W., M.D., F.R.C.P.L., Downing Professor of Medicine at the University of Cambridge.

LAURIE, J., M.D., a Dispensary Physician to the Royal Infirmary, Glasgow.

LOTHIAN, J. A., M.D., L.R.C.S.Ed., an Extra Dispensary Surgeon to the Royal Infirmary, Glasgow.

M'EWM, W., M.D., a Dispensary Surgeon to the Royal Infirmary, Glasgow.

MATHER, G. R., M.D., a Dispensary Physician to the Royal Infirmary, Glasgow.

PALEY, J. H., L.R.C.P., M.R.C.S.E., Resident Medical Officer to the Ripon Dispensary.

ROBERTSON, Dr., Resident Medical Officer to the Carlisle Fever Hospital.

ROBERTSON, E. B., M.B., Medical Officer to the Stepney Union Workhouse.

TAYLOR, F. A., M.R.C.S.E., Medical Officer of Health for the Wells, Norfolk, Urban, and Port Sanitary Districts.

TERREY, C., M.R.C.S.E., Medical Officer for the Workhouse of the Newport Pagnel Union.

THOMAS, W., F.R.C.S., Honorary Surgeon to the Birmingham and Midland Free Hospital for Sick Children.

THOMSON, S. J., M.R.C.S.E., House Surgeon to the Kent and Canterbury Hospital.

TRENNER, G. W., M.R.C.S.E., Medical Officer of Health for the Falmouth Rural Sanitary District.

WEIR, J., M.B., a Dispensary Physician to the Royal Infirmary, Glasgow.

WHITSON, J., M.B., C.M., an Extra Dispensary Surgeon to the Royal Infirmary, Glasgow.

WILLIAMS, F., M.R.C.S.E., Medical Officer of Health for the Launceston Rural Sanitary District.

WYBRANTS, J. H., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer for the Kelmsedon District of the Frome Union, Somersetshire.

#### Marriages.

EVANS—BUNNACKS.—On the 1st inst., at St. Andrew's Church, Hasted, Samuel Evans, L.R.C.P., M.R.C.S., of Harwich, to Sarah Sophia, youngest daughter of the late Harcourt Bunnacks, of Harwich.

HAMERTON—THOMPSON.—On the 26th ult., at Golden Church, co. Tipperary, Morran Fox Hamerton, M.B., M.Ch., T.C.D., to Sarah Anne, second daughter of George Thompson, Esq., Kilmore House, Cashel.

#### Deaths.

GILKETT.—On the 3rd Dec., at 77 Vauxhall Bridge Road, London, Wm. Gillett, L.R.C.P.Ed., aged 49.

HAWES.—On the 26th Nov., Robt. Hawes, M.R.C.S.E., of Wimborne Minster, aged 74.

JAMES.—On the 19th Nov., Thos. James, M.R.C.S.E., of Marine Terrace, Aberystwith, aged 58.

LESLIE.—On the 2nd Dec., at Armagh, James Leslie, M.D.

MARKS.—On the 26th Nov., of scarlatina, at 26 Hatch Street, Dublin, Emily, wife of Alex. H. Marks, M.D.

MACINTYRE.—On the 28th Nov., James MacIntyre, L.R.C.S.Ed., of London Road, Glasgow, aged 45.

SMALLMAN.—On the 23rd Nov., at Lincoln, J. C. B. Smallman, M.D., of Willingham, near Gainsborough, aged 40.

SMITH.—On the 25th Nov., Wm. Scott Smith, L.S.A.L., of Eastwood Notts, aged 74.

SUTHERLAND.—On the 25th Nov., at George Street, Croydon, William Sutherland, M.D., M.R.C.S., in his 63rd year.

WILSON.—On the 29th Nov., at Bryanston Street, Portman Square, Wm. T. Wilson, L.K.Q.C.P.I., late Staff Surgeon H.M.S. Iron Duke.

**SPARKLING WINES FROM SAUMUR.**—An interesting article has just appeared in the *Medical Times and Gazette* on Sparkling Wines. In consequence of the recent rise in the price of Champagnes, it appears that attention has been directed to the district of Saumur, in the north-western portion of France. Dr. Druiitt, the author of the article in question, remarks:—"Both in society and in medical practice the use of Sparkling Wine is largely on the increase. Nothing is so exhilarating with so small a quantity of alcohol in it," and adds that the wines of Saumur, "although perfectly familiar in London, have hitherto been decorated with other names than their own," and that "every year 4,000,000 bottles of wine from Saumur are sent to this country, where it has been ticketed with any name the purchaser chooses to give it." He concludes his article with the following advice:—"It surely is foolish to give 4s. or 5s. for a second-rate Champagne, when a wine which is either the same identically, or rather one better than the second-rate brands of Champagne, may be had for less money." One firm, the Messrs. W. and A. Gilbey, of London, are introducing these wines through the medium of their Agents in every town, under what Dr. Druiitt calls, "the modest and true appellation of Sparkling Wines of Saumur."—[*Morning Post*, December 2nd, 1874.]

**ROYAL COLLEGE of PHYSICIANS of LONDON.**—The NEXT PROFESSIONAL EXAMINATION for the MEMBERSHIP will commence on THURSDAY, JANUARY 21.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all Certificates and Testimonials required by the Bye-laws are to be left at the same time.

Fall Mall East.

H. A. PITMAN, M.D., Registrar.

**PARTNERSHIP, £150.** For this small amount a SURGEON can become a PARTNER in a well-established practice, and have a certain amount of Income guaranteed and secured to him. Fine double-fronted shop, in a good thoroughfare, centrally situated. Profits, on the ready money alone taken over the counter, upwards of £2 per week. A Partner who could do the outdoor work would double the receipts, as this branch has never been attended to. Trial allowed. Messrs. DEBENHAM and CO., Auctioneers, 2 King's Road, Bedford Row, London, W.C.

**NORTH-EASTERN HOSPITAL for CHILDREN,** HACKNEY ROAD, E.—HOUSE-SURGEON required for the above Institution. Salary, £100, with attendance, rooms, coals, and light. Double qualification preferred. Apply by letter, stating age, with Testimonials, &c., to the Secretary, Mr. J. W. Sibbey.

#### INDIAN MEDICAL SERVICE:

**NOTICE is HEREBY GIVEN,** that an EXAMINATION of CANDIDATES for Twenty Appointments as Surgeon in Her Majesty's Indian Medical Service will be held in London in February, 1-75.

Copies of the Regulations for the Examination, together with information regarding Pay and Retiring Allowances of Indian Medical Officers, may be obtained on application at the Military Department, India Office, London, S. W.

A further notice will be issued when the exact date of examination has been fixed.

T. T. PEARSON, Major-General, Military Secretary.

India Office, 1st December, 1874

**SURGICAL SOCIETY OF IRELAND.**—The SECOND MEETING of the SOCIETY will take place on FRIDAY EVENING, 11th DECEMBER, 1874.

Chair will be taken at half-past eight o'clock precisely.

H. WILLY RICHARDSON, F.R.C.S.I., } Hon. Secs.

HUMPHREY MINCHIN, F.R.C.S.I., }

Royal College of Surgeons, Dublin,

26th day of Nov., 1874.

## The Medical Press and Circular

### OFFERS UNUSUAL ADVANTAGES

**FOR** the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

## PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.,  
&c. (KING'S COLL.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

**PRACTICES AND PARTNERSHIPS NOW OPEN** for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

**Z 74. WILTS.** Easily-worked PRACTICE and APPOINTMENTS for SALE, in a pleasant locality, with direct railway communication. The receipts are nearly £400 a year. Appointments, £150. The house is large and convenient, with garden, stabling, &c. Midwifery, £1 ls. and upwards. An efficient introduction can be given, and there is great scope for increase.

**Z 73. LONDON SUBURBS. DEATH VACANCY.** In a populous district, near Regent's Park, the SUCCESSION to a TRANSFERABLE PRACTICE, returning £600 a year, can be secured by an active gentleman on easy terms. The house has been for many years a medical residence, and the widow can give an effective introduction. Terms, £450, of which the greater part may be paid by instalments properly secured.

**Z 72. SALOP.** Old-established COUNTRY PRACTICE for TRANSFER. Receipts, £500 a year. Midwifery, £1 ls. to £5 5s. About 36 cases annually. No opposition. House contains 11 rooms, with detached cottage, stabling, large garden, and land. Rent, £50. Advancing age the cause of retirement. Premium, 1 year's purchase, part of which may remain on security.

**Z 71. PARTNERSHIP in a well-established TOWN and COUNTRY PRACTICE.** Average receipts about £1,100 a year. Appointments yield £200. Midwifery, £1 ls. to £5 5s. Patients good class. A third share, with succession to one half is offered, or the whole would be sold with a quasi partnership introduction. The residence is large and very convenient, with garden, stabling, &c. Held on lease at a rental of 50 guineas. The highest references can be given.

**Z 70. DEATH VACANCY.** Within 70 miles of London, the SUCCESSION to an unopposed COUNTRY PRACTICE, upon easy terms. The connection has been held by late Incumbent for 30 years. The receipts are estimated to have been about £500 a year; but there is scope for a much larger practice. Appointments £75. District agricultural. Convenient house, with offices. Rent £30. Railway station within 4 miles. Deceased died on the 25th inst.

**Z 68.** In a good agricultural district, a PRACTICE of £600 a year FOR TRANSFER. Appointments £280. No opposition. The house contains ten rooms, with stabling, garden, &c. Rent £26. Midwifery fees £1 ls. and upwards, except in the case of a few old patients. The locality is about 100 miles from London. Railway station within a few miles. To a suitable gentleman, free to enter at once, easy terms would be conceded.

**Z 46. EXCELLENT NUCLEUS,** specially suited to a Catholic gentleman. The receipts during the past year have been £250, and the connection promises to become large and select. Convenient house and detached cottage. Rent £26 a year. The Incumbent having in view a valuable public appointment, desires to make an immediate arrangement.

### ON THE SCIENTIFIC AND EMPIRICAL INVESTIGATION OF EPILEPSIES.

By J. HUGHLINGS JACKSON, M.D., F.R.C.P.,  
Physician to the Hospital for the Epileptic and Paralysed, and to the London Hospital.

#### CHAPTER III. (concluded).

AFTER these digressions, purposely made in order to show principles of classification, which are to be applied so far as possible to all kinds of cases of nervous disease, I return to Epilepsies.

I admit two classifications to the Empirical Classification, or rather Arrangement of Varieties of Epilepsies, and of Epileptiform Convulsions would be—

#### EMPIRICAL ARRANGEMENT.

##### A. Epilepsy Proper.

- (1) Vertigo.
- (2) Petit mal.
- (3) Grand mal.

##### B. Epileptiform, or Epileptoid.

- (1) Convulsions beginning unilaterally.
- (2) Unilateral Dysesthesia (migraine)
- (3) Epileptiform Amaurosis.

&c.

Plainly enough, such an arrangement goes by what is most superficial or striking. The advantages of it are obvious. It facilitates identification and the application of knowledge to utilitarian purposes. But it must not be trusted as a natural classification. However much it may be further elaborated, it can make not even an approach to a scientific classification. No amount of refined sub-division starting from a definition which makes loss of consciousness a symptom *sui generis*, would make the arrangement a natural classification, for there would never be points of contact with other classes of nervous diseases or symptoms. No common principle underlies it. It is a great misfor-

tune when a student takes such an arrangement, founded obviously on superficial differences and resemblances, as a natural system, and endeavours only to see if a given case approach nearest this or that entity. The clinical divisions are avowedly artificial. Authorities are fully agreed on this point. As regards the clinical divisions of the symptoms of epilepsy (of what, in the arrangement, is called epilepsy proper), there are very many intermediate degrees traceable. On this point authorities agree—they agree, that is to say, as to the clinical facts. (a) There are, clinically, degrees traceable from a slight and transient loss of consciousness, (b) which, to give an example, simply permits the hand to fall in raising a fork to the mouth, the mouthful being the very next moment safely delivered, to severe universal convulsions, with loss of consciousness, followed by deep coma. So far, I speak of different cases. The same patient may have seizures of different degrees, sometimes *petit mal* and sometimes *grand mal*. Again, a patient, after being for months subject to *petit mal*, or even to slight vertigo, becomes subject to the *grand mal*, or to both; and

(a) They do not admit that they are degrees in the sense which I hold them to be—viz., as being due to discharges of different degrees beginning in (*see* Chap. II., p. 411) the highest centres of the cerebral hemispheres.

Let me state the differences categorically. The reader is reminded that the epilepsy of authorities ("idiopathic epilepsy") is spoken of.

The accepted opinion is that two different and distant parts (the medulla oblongata and the cerebral hemisphere) are concerned in the epileptic paroxysm. I think but one part, the cerebral hemisphere, is concerned, and that of this only the highest centres are the seat of the discharging lesion. (The discharge, of course, spreads through lower centres.)

The accepted view assumes two different processes—(1) a discharge of the medulla oblongata, and (2) a contraction of the arteries of the brain. Correspondingly there are, according to it, two essentially different states—(1) passive, in the cerebral hemisphere, and (2) active, in the medulla oblongata. I think there is but one process in the paroxysm, an active one—that is, a discharge beginning in the highest processes of the cerebral hemisphere. Consciousness will be lost during the excessive excitation of these processes.

(b) Loss of adjustment, &c.

in many cases of patients who suffer both there is clear proof that the *petit mal* is an abortive fit—i.e., the initial stage of the *grand mal*. In these cases the *petit mal* merges into the *grand mal*. Then, although we have illustrated by loss of consciousness there are really in slight attacks of epileptic vertigo, or *petit mal*, all degrees of affection of consciousness. It is not very uncommon for a patient to have for months sudden and short queer feelings at the epigastrium, and a little confusion of thought, which conditions later on he recognises as being just the same as the initial symptoms of his attacks of *petit mal* and of *grand mal*. As mentioned (Chap. II., p. 411), a patient may tell us that he is confused only, and will say that he hears people talking, but does not know what they say. This is only defect of consciousness. Again, we see, as has been repeatedly stated, that there are all degrees of automatism after different degrees of epileptic seizures, and this is indirect evidence of all degrees or depths of implication of the anatomical substrata of consciousness.

If we take cases of what are called "epileptiform" seizures, we find all degrees even in the same patient—we find, for example, attacks of convulsion of the arm without a trace of affection of consciousness; and again, attacks in which he loses consciousness, and is deeply comatose when the fit is over. There are, indeed, all degrees of discharges, from those causing twitching of the index finger to those causing universal convulsion. Similarly, there are very numerous degrees of paralysis after convulsion of different degrees of violence, from numbness of a hand to hemiplegia with lateral deviation of the eyes.

However convenient the empirical division may be clinically, and I admit its convenience, the division is not an anatomico-physiological one; it is, I think, of psychological parentage.

So, in admitting the necessity for clinical purposes of an arrangement of varieties of epilepsy, I urge that in a scientific classification we must start from a more fundamenal basis. The one I suggest is that there is in each epilepsy a sudden and violent discharge, and that those varieties called by authorities genuine epilepsy are explainable on the supposition of a discharge beginning in the highest series of nervous processes. Other seizures begin in series of a lower range of evolution (subordinate series)—for example, convulsions beginning in hand, face, foot, &c.

In this book I deal chiefly with the Scientific Investigation of epilepsy but I must frequently speak of the Empirical Investigation: it will be absolutely necessary to do so. What I hope I shall not do is to mix the two classifications.

The reader who does not make allowances for the distinctions I have made may give reasons for rejecting my method altogether but if he does reject it he can scarcely be considered a fair critic of details. A botanist would not think a gardener ignorant because he put together his plants as they were of use for eating or for ornament; and a gardener would not think a botanist ignorant because he classified plants, regardless of their being herbs, trees, or shrubs. Let me state the method anew.

In the Scientific Investigation of a case in which there is loss of consciousness, vertigo, convulsion, or any symptom whatever presented paroxysmally, the endeavour is not to determine if there be any approach to or departure from any clinical standard—to, or from, what has been described as genuine epilepsy for example. There being occasionally a paroxysmal presentation of symptoms (see List, p. 392), an internal and local discharging lesion is inferred. Since any part of the convolitional surface of the brain may become unstable—may become the seat of a "discharging lesion"—there will be many varieties (a) of epilepsy. Since the size of the discharging lesion will vary, and as probably

the grey matter affected differs in degree of instability, there will be seizures not only of all kinds, but of all degrees. Not only will the paroxysms of different patients differ in that, as, for an example, the paroxysms in one affect first the leg—in another, first the arm, but there will be such differences as that of two fits beginning in the hand: one is limited to the arm, and the other spreads all over the body.

We must, however, even in the Scientific Classification and Investigation, make arbitrary divisions—for instance, we shall speak of three degrees of convulsions beginning unilaterally; we shall be obliged to do so. All classifications in all sciences make distinctions more exact and abrupt than any that exist in nature.

It may seem to the reader that this is returning to the old method. In the first place, the new method takes count of all kinds of paroxysmal discharges, even such as "subjective" sensations of smell. And in speaking of degrees we do so only for the sake of exposition. In actual practice we encounter all conceivable degrees. And this method necessitates a precise study of what occurs in the paroxysm in each case on its own merits, regardless whether it approaches any arbitrary standard, and equally regardless whether it be one of the degrees spoken of for clearness of exposition in the Scientific investigation. It necessitates also a very careful localisation of the changes discoverable *post mortem*; for, as stated, every epileptic paroxysm is considered as a brutal development of the function of some part of the brain.

The researches of Hitzig and Ferrier will help this investigation to an extent difficult to over-estimate; for I most willingly admit that the method I uphold has made very little way. From their researches we shall learn where to look for the minute changes which constitute the discharging lesions in different epilepsies. Whatever interpretation may be put on their facts, there is no doubt, at any rate, that irritation of different parts of the surface of the brain leads to different classes of movements. Correspondingly, there is no doubt that at least some epilepsies beginning by movements in different parts of the body depend on "disease" of different parts of the surface of the cerebral hemisphere.

#### APPENDIX TO CHAPTER III.

The following is the quotation referred to at page 476:

"Let us first consider the *range* of the term [Epilepsy], let us see what disorders are properly ranked under this head. It is no easy matter to do this exactly and correctly; we may err in two ways: on the one hand, by too closely restricting our conception of the disease to its more classical types, and so leaving out of count and consideration a great number of more or less closely allied derangements; and the other, by two great laxity in the use of the term, leading us to overlook important distinguishing circumstances. We shall best meet this difficulty, I think, by referring to the principle so well laid down by Whewell ('Philos. of Ind. Sci.' vol. i., p. 494). This is that Natural groups are determined not by Definition, but by Type; not by a boundary line without, but by a central point within; not by what they strictly include, but by what they eminently include; by an example, not by a precept. 'A type,' he proceeds, 'is an example of any class, for instance, a species of a genus which is considered as eminently possessing the characters of the class. All the species which have a greater affinity with this type-species than with any others form the genus, and are ranged about it, deviating from it in various directions and different degrees. Thus, a genus may consist of several species which approach very near the type, and of which the claim to a place with it is obvious; while there may be other species which straggle further from this central knot and which yet are clearly more connected with it than with any other. And even if there should be some species of which the place is dubious, and which appear to be equally bound to two generic types, it is easily seen that this would not destroy the reality of the generic

(a) It does not follow that there will be as many practically as are theoretically possible; for some parts of the brain are more often damaged than other parts—the Sylvian region, for example; this is a consequence of arterial arrangements. When I come to speak of Pathology I shall consider this subject, and especially with regard to embolism and thrombosis, as possible pathological processes in inducing local "discharging lesions."

groups any more than the scattered trees of the intervening plain prevent our speaking intelligibly of the distinct forests of two separate hills.' To apply this to the case before us. It appears to me that, taking the convulsive form in its entirety, for the type, it shades off on one side by the *petit mal* into mere vertigo, on another, into hysteria and choreic convulsion, on a third, into delirium, catalepsy, and somnambulism, on a fourth, into neuralgia. Convulsion and unconsciousness, recurring more or less frequently, are the grand features of epilepsy, but the former symptom we know may be often absent, and though the latter, in a greater or less degree, is much more constant, it is occasionally much attenuated or wanting. I make this statement on the authority of Trousseau and Sieveking, which my own experience tends to confirm. When the intervals are very long, several years for instance, the character of recurrence loses most of its value. This character is further weakened by the circumstance that the intervals are by no means always free from various morbid phenomena, similar in kind, but less in degree than those which constitute the paroxysm. Thus, the convulsive fits may come to be few and far between, but attacks of giddiness may be pretty frequent, and of somewhat long duration, and these mark the persistence of the disorder almost as much as the fits. Viewing this malady from its *phenomenal* side, I can only express my entire concurrence with what my friend, Dr. Sieveking, has said—"That several of the diseases that are commonly regarded as residing mainly in the nervous system merge into one another, and that the boundaries by which they would appear to be circumscribed by nosologists are by no means so uniformly to be traced." (Dr. Handfield Jones on "Functional Nervous Disorders," Art. "Epilepsy," p. 285.)

(To be continued.)

## ON THE TREATMENT OF FISTULOUS SINUSES BY MEANS OF THE ELASTIC LIGATURE.

By W. ALLINGHAM, F.R.C.S.,

Surgeon to St. Mark's Hospital, &c., &c.

(Continued from page 500.)

CASE XX.—G. H., *æt.* 39. Complete fistula; operation October 12; ligature came away 6th day; delicate phthisical man; bad cough, and night sweats; wound quite healed in twenty-one days, and health improved considerably.

It will be apparent from the above cases that I have not found the ligature separate quite so rapidly as Prof. Dittel and other gentlemen say it has in their experience—viz., in two, three, and four days. The shortest time in my cases has been four days, and the average in twenty-eight cases of fistula in ano was six and a half days. In none of my patients has there been sufficient pain to give rise to any constitutional disturbance; there was never any fever, and the increase of temperature at night was, as shown by the thermometer, most trivial; although some complained of pain during the first night they mostly slept fairly without any opiate.

I had employed the india-rubber ligature in very few cases only before I came to the conclusion, that if I intended operating frequently, or if ever the method were to become popular, other and better means must be devised for the introduction of the ligature through the fistula than those recommended and used by Prof. Dittel. The Professor described several ways of accomplishing the end in view, all of which appeared to me theoretically to be imperfect, and I found them, practically, clumsy, difficult of performance, tedious, and exceedingly painful to the patient. For complete fistula he used a probe with an eye near its point, which was to be passed from without to within, carrying the india-rubber and a strong thread, so that if the india-rubber broke in tying it, another ligature could be drawn by it through the sinus. Another method was to pass a tubular probe; through the tube a fine wire was to be introduced, and

the end fished down with the finger in the bowel; then the probe was to be withdrawn, so that the wire traversed the fistula, one end hanging from the outer opening, the other emerging from the anus; the india-rubber was then to be fastened to the wire, and drawn through the fistula. This was really a very difficult task to accomplish; sometimes the wire broke, and the probe had to be re-introduced, so it was found better to attach to the wire a piece of strong thin cord and draw that through the probe, then to fix the india-rubber, which in its turn was finally got into the desired position. I need scarcely say this is a very lengthy as well as painful mode of procedure, as the thin wire or cord cuts the inner opening of the fistula. When the fistula was not complete, Prof. Dittel recommends a director to be passed as far as possible up the sinus and along the groove; a sharp needle armed with the india-rubber was to be carried, and the bowel perforated, the ligature drawn from the eye of the needle by the finger, and the needle removed. This, I may remark, if the sinus runs far up the bowel, is by no means so simple of accomplishment as it may appear. Being, then, very dissatisfied with these methods of operating, I set myself to find some better and simpler plan, and on reflection, I came to the conclusion that the india-rubber could be drawn much more readily from within the rectum through the internal opening (or through an artificial perforation in the bowel) than by commencing to pass it from the external opening. This conviction led me to devise this simple instrument (which is shown in the wood-cut) for drawing a ligature through a fistulous sinus or beneath a tumour, and Messrs. Krohne and Sesemann have with much care and pains rendered it, in my opinion, practically quite perfect.

It consists, as will be seen, in the combination of a concealed hook or notch, with a blunt or sharp-pointed probe, as the case may require. A shows the curved probe with the hook concealed by the sliding canula, ready to be passed through a fistula, or, if a sharp point be substituted for a blunt one, under a tumour. B exhibits the instrument with the canula drawn back, and the previously concealed notch exposed, ready to receive the loop of india-rubber; when this is placed in the notch, the canula is pushed home, and the ligature is held so firmly that it cannot escape. Thus a double ligature can be readily drawn through a fistula or beneath a tumour. It is not necessary in fistula to see the hook, for if the finger, with a loop of india-rubber around it, be passed up the rectum, the loop can with perfect facility be directed over the end of the probe and caught in the notch quite unaided by vision. C shows the sharp-pointed instrument adapted to the same canula, so that only one handle and one canula are required to complete the double instrument. You see that with my instrument a double ligature is brought through the sinus; this is an advantage, especially if you tie the ligature, as in thus securing it you are very apt to break the india-rubber, and you have the second ligature to fall back upon: but I told you that I had abandoned the knot, and I now only use a small, soft-metal, oval ring; the two ends of the india-rubber are threaded through this, the rubber is pulled as tight as you require it, and the metal ring is then closed by a strong pair of forceps; this holds perfectly tightly, it never breaks the ligature, never gives way, and is done in a moment.

In conclusion, gentlemen, allow me to repeat that I do not consider the elastic ligature can ever supplant the knife in the treatment of fistulous sinuses. In complicated cases the knife must be depended upon mainly; but I am of opinion that the india-rubber is valuable in many cases as a substitute, and in others as an auxiliary, to the usually employed method of incision.

### INJURIOUS EFFECT OF THE CONTINUED EXHIBITION OF CHLORAL.

By FRANCIS M. LUTHER, M.D., M.R.C.S.E.

"NULLUM remedium quin solo tempestivo usu tale fiat" says the old adage—"Timely use alone makes any drug a remedy." Slaking a blazing fire is expedient to prolong its existence, but slaking the same fire when it is smouldering will only put it out. The remedy, then, will be, first to rake out the ashes, and after that to replenish the fuel. Chloral is a most valuable remedy for the earlier stages of many nervous maladies, accompanied by loss of sleep; but if its administration is too long continued—say, for months or years—hyperæsthesia will be succeeded by anæsthesia, morbid sensibility will give place to morbid dulness, and most of the phenomena of chronic intoxication will be produced. The writer is aware of a case where an entire family of adults took chloral for very many months. At first it was quickly absorbed, and doses of half a drachm produced sleep in less than half-an-hour. Ten or fifteen grains answered one individual. The artificial sleep lasted with some of the family four or five hours, when the drug seemed to be in a great degree eliminated from the system. If the patient was very irritable on going to bed, no further sleep was had that night; but if less so, the artificial sleep slid into the natural one. When the sleep was not sufficiently prolonged to allow of the chloral to be eliminated from the system, the phenomena evinced were precisely like intoxication. However, at first it did seem to be eliminated tolerably well, and was of decided service in calming nervous irritability, the effect varying very much with the individual. The doses exhibited were probably needlessly large. A large dose often failed in producing anything but a nightmare stupor, if the person went to bed angry, owing probably to the stomach containing acid, a small dose sufficing the same individual when the frame of mind was tranquil. After a time—how long I cannot say—each individual began to complain of a constant feeling of chilliness, owing probably to depressed nerve power, and also to the chloral hindering oxydation. Dyspepsia, to which three of the individuals were more or less previously subject, became terribly aggravated, and the fourth, who had enjoyed a good digestion, became likewise dyspeptic. Symptoms threatening imbecility and general paralysis showed in three, the one who escaped being the one who took but a very small dose (ten or fifteen grains). A hæmorrhage from bleeding piles, to which one had been subject for many years, and which was well borne while the loss was made good by well-digested food, now, when digestion was completely paralysed, became constant, and threatened to prove fatal. No purpura was observed, if it existed. Now, I do not mean to say that the chloral *alone* caused this terrible assemblage of symptoms. Manifold troubles, confinement to the house, and weak and excitable nervous systems, had all their share in producing it; but when, by a great effort, the chloral was abandoned by all, the improvement was so great after a while as to show how injurious its continued exhibition had been. The principal noxious effect of the chloral when exhibited too long is that it hinders elimination of the waste of the tissues, and so clogs the whole vital machine. In the malady alluded to, and in a less degree in all nervous diseases, there is excessive disintegration of nerve-tissue, and the blood is imperfectly oxydised; hence the indica-

tion for treatment is to lessen waste, to further elimination, and to increase oxydation. Avoid work beyond your strength, or responsibilities beyond your capacity; avoid all avoidable worries, or dismiss them from consideration when fairly attended to; avoid all unwholesome excitement, or dissipation; but seek the society of healthy, kindly, sensible people. Let your occupation be healthful, useful, and fairly remunerative in every sense of the word. Eliminate waste by taking frequent Turkish baths. Take purgatives occasionally if required. Favour oxydation by being as much in the fresh air as you can, without exhausting your strength. The Turkish bath will enable you to be much more in the fresh air than you otherwise could. Wear light clothing, to allow free access of air to the skin. This, too, the bath makes easy. Use a fair share of farinaceous and vegetable food with your diet, which taxes oxydation less than a purely animal diet; but whatever kind your food, eat it surrounded by cheerful influences, and it will agree with you; whereas both the stalled ox and the dinner of herbs will disagree if eaten in the midst of turmoil. Let those who have inherited a tendency to nervous maladies observe these rules, and they will have cause to congratulate themselves. As curative measures they will have more or less success, but are difficult, and can't be used simultaneously.

## Hospital Reports.

### ROYAL MOORFIELDS OPHTHALMIC HOSPITAL.

Dec. 4.—Mr. Couper operated on a case of glaucoma by iridectomy of left eye. The left eye was quite blind, and the right was gradually losing its vision. The patient was a man about 50 years of age, who had been a great smoker, and was sent to Mr. Couper by Dr. Drysdale, with the query whether the effect might have been produced by that cause. There was deep cupping noticed in the right eye.

The next case was one of caries of the nasal duct in a young girl, caused by swelling, and impeding of downflow of tears, and irritation, ensuing in abscess and caries of the bone around the sac. The abscess had first been opened in the cheek, and afterwards both lachrymal canaliculi were laid open and probes of increasing calibre passed. The girl was of strumous diathesis.

The third case was that of prolapse of the iris, occurring in a child, occasioned by a penknife, which had made an incised wound through the lower sclerotic at its junction with the cornea, in the left eye. Mr. Couper cut away the prolapsed iris and passed a suture through the incised edges, bringing them together.

### TYRONE INFIRMARY.

#### *Removal of Tumour by Esmarch's Apparatus.*

By EDWARD C. THOMPSON, M.B., Omagh.

MARGARET CAMPBELL, æt. 62, was admitted into the Tyrone Infirmary, suffering from a cancerous tumour of the leg. I considered this a favourable case for the employment of Esmarch's apparatus for bloodless operations. Accordingly the elastic bandage was applied, and the leg carefully bandaged from the foot to the knee, the tubing was then wound round the leg several times, and the bandage removed. The tumour was rapidly excised, without the loss of a single drop of blood, and with scarcely any pain. This case may appear to many of your readers hardly worth reporting; but where any new line of treatment is proposed, it seems to me desirable to accumulate as many cases as possible to determine its value.

## LECTURES ON HUMAN ANATOMY.

By WALTER RIVINGTON, M.S. Lond., F.R.C.S. Eng.,  
Surgeon to the London Hospital, and Lecturer on Anatomy at the  
London Hospital Medical College.

## LECTURE XI. (continued from page 112).

THE student who has mastered the account already given of the separate bones will have no difficulty in combining his knowledge and describing the THORAX AS A WHOLE. The points on the *Exterior* most worthy of observation are the forward and downward slope of the Sternum, the shape, size, and direction of the Ensiform Cartilage, the relative lengths and obliquity of the Ribs, the relative length and width of the Costal Cartilages and the Intercostal Spaces. These spaces are widest between the anterior parts of the Ribs. Below the third they narrow rapidly, and often become pointed as they approach the Sternum, and then contract again as they extend towards the Spine. They are filled by the Intercostal Muscles. The anterior wall formed by the Sternum is only a little more than half the length of the posterior formed by the Dorsal Vertebrae. Laterally, the walls are convex, and expand as we trace them from above downwards. Behind, the Necks of the Ribs appear rising above the Transverse Processes, and the Angles of the Ribs form an oblique line slanting from above downwards and outwards.

Observe how the backward curve of the Ribs brings them nearly to a level with the Spinous Processes, and enables the Human Body to lie comfortably on the back.

In the *Interior* we notice the prominence of the Bodies of the Dorsal Vertebrae in the middle line behind and a deep groove on each side of the Spine, extending outwards as far as the Angles of the Ribs. This groove is peculiar to man, and lodges the thick posterior border of the Lung. The dimensions of the Cavity at different parts should claim careful attention. In the well-formed adult the *transverse* diameter in the middle and lower part of the Thorax measures eight or nine inches, exceeds considerably the longest *antero-posterior* diameter, and is more than double the distance between the Sternum and the Dorsal Vertebrae, which averages four inches.

Of the two *Apertures* of the Thorax, the *superior* or *cervical* is much smaller than the *inferior* or *abdominal*. It is heart-shaped, and has its long diameter transverse. Like the first pair of Ribs which bound it laterally, it slopes from behind forwards and downwards. In front is the *Episternal Notch*, lying between the projecting sternal ends of the Clavicles, and behind is the first Dorsal Vertebra. Through this opening pass many important structures, the bare enumeration of which at this stage of your anatomical knowledge would not tend to your edification; but we may mention the Wind-pipe, or Trachea, the Food-pipe, or Oesophagus, the great Blood-vessels of the Head and Neck and Upper Limbs, and two nerves most essential to the preservation of life, by sustaining the breathing process—the Phrenic and Pneumogastric.

The upper ends, or apices of the Lungs, covered by their investing membranes—the Pleurae—project above the first Ribs into the root of the Neck, and are protected by a dome-like expansion of the cervical fascia, which may be said to close the superior aperture of the Thorax.

The *inferior aperture* is very large, and is bounded by an irregular margin. In front is the Ensiform Cartilage, separated on each side by a notch from a convex sloping edge formed by the conjoined cartilages of the Vertebro-Costal Ribs; lower down are the tips of the Vertebral Ribs; and behind is the inferior border of the Twelfth Rib, sloping upwards and inwards, and joining the Spine at an acute angle. The plane of the opening slopes from before downwards and backwards, and is occupied by the arched and inclined musculo-tendinous partition, or Diaphragm, which is found in all the Mammalia separating the Thorax from the Abdomen. The Diaphragm is composed of a central tendon, surrounded by muscular fibres. To the central tendon is fastened above the Aponeurotic Case, or Pericardium, which contains and protects the Heart; the lateral fleshy portions curve upwards into the cavity of the Thorax, and support the bases of the Lungs, to which they correspond accurately in shape and size. The narrow central region of the Thorax lying between the Sternum and the Spine is occupied by the Heart, the great Blood-vessels connected with the Heart, the Trachea, Oesophagus, and some important Nerves. It corresponds below to the central tendon of the Diaphragm, and undergoes comparatively slight alterations during the breathing process. The

lateral compartments of the Thorax are filled by the Lungs, are bounded below by the muscular fibres of the Diaphragm, and are very movable. The breathing process, or Respiration, for which the Thorax is specially adapted, consists of two parts—the admission of air into the Lungs, or Inspiration, and the expulsion of air from the Lungs, or Expiration. In the condition of rest the walls of the Thorax are in an intermediate state between dilatation and contraction, and when drawn either outwards or inwards will return to this state by virtue of their inherent Elasticity. The act of inspiration being performed in opposition both to the Elasticity of the Thorax and the pressure of the atmosphere, requires the expenditure of active muscular power; and hence it is that we find so many strong muscles having an inspiratory office attached to the walls of the Thorax. In an ordinary tranquil inspiration most of these muscles contract but slightly, if at all, and the Ribs are not altered in position much more than the twentieth of an inch, the abdominal movement, according to Dr. Sibson, being about one-third of an inch, and the diaphragm descending about half an inch; in an ordinary expiration the Elasticity of the walls of the Thorax and of the Lungs suffices to restore the Thorax to its middle state. In proportion as the inspiratory efforts increase more muscles are brought into action, and their contraction becomes more vehement; when expiration requires to be carried beyond the usual limits the active force of muscles capable of effecting compression of the parts must be exercised in opposition to the natural elasticity.

The Thorax is so admirably constructed as to be capable of enlargement in every dimension, and to allow the air to enter freely into all parts, even the most distant corners, of the Lungs. All its diameters—the vertical, the antero-posterior, and the transverse—are enlarged in inspiration. The *vertical capacity* of the Thorax is increased by the contraction of the muscular fibres of the Diaphragm, which straighten themselves and descend towards the Abdomen, pressing downwards the Abdominal Viscera, and causing air to enter into the lower parts of the Lungs. The *antero-posterior capacity* of the Thorax is increased by the elevation of the anterior ends of the Ribs and Costal Cartilages, a movement by which they are necessarily carried forwards as well as upwards, bearing the Sternum with them. The *transverse capacity* of the Thorax is increased by the rotation of the Ribs on an Axis drawn through the vertebral and sternal joints, such an Axis being analogous to the string attached to the two ends of a bow. The rotation of the Ribs and Cartilages on this Axis involves an elevation of their middle parts, and their removal from the median line of the Thorax and the Cartilages are said to undergo a torsion which calls into play an elastic reaction favourable to expiration. It is interesting to notice that there is an exact correspondence between the bulk of the Lungs at different parts and the mobility of the Ribs in kind and in degree. The narrow Apex of the Lung is in contact with the first Rib, which is the least oblique of the series, and simply moves upwards and downwards. As the Lung increases in size, in the same proportion do the Ribs increase in length, obliquity, and variety of movement, as far as the seventh, below which they again diminish. The eleventh and twelfth have simple upward and downward mobility. The Diaphragm ensures the necessary enlargement of the Thorax at the lower part. "The part," says Professor Humphry, "of the ribs between the third and the eighth which is most oblique, and which, by a given amount of movement, causes the greatest alteration in the size of the chest, is the hinder portion of the shaft, the part at and near the angle; and this part is in contact with the thick hinder border of the Lung, where a greater number of air-cells and blood-vessels are crowded together than in any other area of equal size, and where, accordingly, a larger proportion of the work of respiration is carried on." The Thorax has been ingeniously compared by South to a swing, or a series of swings, suspended from a firm support. The comparison holds better in quadrupeds, in whom the Spine, from which the Ribs depend like the rods of a common swing, is horizontal, and in whom the Sternum, or seat of the swing, is carried forwards and backwards by the swinging motion of the Ribs. In Man the Spine is vertical, and the analogy is not so apparent. The swing-like motion of the Ribs, having to be commenced in a direction contrary to gravity, a fixed point or fulcrum is stated by some physiologists to be needed towards which the Ribs can be drawn by the contraction of the Intercostal Muscles. Such a fulcrum is described as being afforded by the first pair of ribs, which is supported by strong muscles descending from the Vertebrae, and from which the rest of the Thorax may be regarded as

suspended. Fastened to the Sternum by very strong cartilages, they form a rigid ring, whose elevation would appear necessarily to involve the elevation of the rest of the bony framework. Thus, Haller regarded the first rib as a fixed point, towards which each of the other ribs was drawn in regular succession from above downwards. Dr. Hutchinson says: "The clavicles, shoulders, scapulae, and superior ribs are raised, the sternum advances, the infra-clavicular region swells remarkably upwards and outwards (particularly in females), like a rolling wave, the supra-clavicular region is raised, the whole apex of the thorax is rendered more obtuse, particularly the antero-posterior diameter. The lower ribs at their cartilaginous extremities spread outwards, increasing both the lateral and antero-posterior diameter of the base of the thorax, the cartilaginous (Gothic) arch formed by the junctions of the sixth, seventh, eighth, ninth, and tenth ribs below the sternum becomes more obtuse by their lateral motion, the abdominal space under this arch down to the umbilicus sinks inwards. There is an indescribable undulating roll produced by the consecutive action of the respective ribs, which always commences with a superior rib; in costal breathing a lower rib never moves first." Humphry observes: "In the normal expansion of the thorax the upper ribs are raised first, the others following in quick succession. In the female the commencement of this movement precedes that of the diaphragm by a very slight interval; whereas in the ordinary inspiration of the male the latter has the precedence." Other physiologists—and among them Majendie and Sibson—consider that all the ribs are moved at once; whilst "Sabatier stated that the ribs differed in the direction of their movement according to their position—the superior ribs moving upwards, the lower ribs downwards, the middle ribs outwards." I quote this from Dr. Ransome's paper on "The Respiratory Movements in Man," read before the Medico-Chirurgical Society in 1872. Dr. Ransome has invented an ingenious instrument, or stethometer, for measuring the movements of the chest; and as his conclusions differ from the accounts usually given and accepted, it will be as well to furnish you with an abstract of them. Before doing so, however, there are two points which I may premise. The first point is that three chief types of respiration have been described, according to the part of the Thorax which is most affected in the act. In the female, for instance, there is a marked expansion and contraction of the upper part of the Thorax, causing the bosom to rise and fall. It is most conspicuous in females on the stage, or in those who are under the influence of genuine emotional impulse. In infants up to the third year and in the aged of both sexes the Diaphragm is the chief agent in respiration, as may be seen by the motions of the Abdominal Walls. In cases of injury and disease of the Spinal Cord the Intercostal Muscles and other inspiratory muscles may be paralysed, and the Diaphragm left alone to perform the work of inspiration. In boys and men the lower Ribs may be observed to act more than the upper Ribs and the Diaphragm. These three types may be distinguished as feminine, or *superior costal*, masculine, or *inferior costal*, and infantile, or *abdominal* respiration. The second point is this: From the statements made by some authors (a) you might be led to conclude that the first Rib had little if any mobility, or, if capable of movement, yet remained immovable in respiration. On this doctrine of the immobility of the first Rib, "originally advanced by Haller," Ward, in his "Osteology," very truly remarks: "It is only necessary to move the Sternum up and down in the dead subject in order to be convinced, with Majendie, that the first Rib is not less movable than any other of the series." What the first Rib wants is the variety of movement possessed by the central Ribs, for while the first Rib can turn freely in a hinge-like manner at its vertebral joints, causing elevation of its anterior end, the longer Ribs appear to move in three ways: the rotation of the head and neck, causing elevation of their anterior ends, and rotation on the antero-posterior axis drawn through their vertebral and sternal joints, causing elevation of the middle of the shafts, have been already mentioned; a third movement is a movement of their anterior ends outwards, effected by the powerful inspiratory muscles which pull on the Sternum and the Ribs. In this movement the cartilages either slide forwards at their sternal joints or remain stationary. Another way in which the capacity of the chest might conceivably be enlarged would

be by the straightening of the Costal Cartilages. Whether any such movement actually occurs or could occur in strong inspiration I will not venture to decide.

Dr. Ransome's views shall be stated as far as possible in his own words: "In ordinary breathing the extent of movement of the ribs is very small, especially in the upper part of the chest, and it is very irregular in extent even in the same person. In both men and women a large part of the respiratory act in ordinary breathing is performed by the diaphragm—a fact remarked by Haller, who says: '*In naturali inspiratione solum movetur diaphragma, costae ad sensum immotis, nisi quod ima una vel altera septi motum sequantur.*' Little information, therefore, as to the action of the chest can be obtained by means of any stethometer except in deep or forced respiration." In the front of the chest in forced breathing the two chief motions are forwards and upwards. "The forward movement is the more equable of the two, and starts much more rapidly at first than the upward motion. In men the upward motion takes place chiefly at the latter part of the respiratory act, when the extraordinary muscles of respiration are brought into play. In most full-chested men the earliest portion of the expansive act seems to be accomplished by an increase of the ordinary action of the diaphragm, then the chest seems gradually to swell outwards in an ascending order from below upwards; the ribs are gradually raised by their special muscles, and the lower ribs are probably at the same time straightened at the anterior angle, between them and their costal cartilages; at last, for the final effort of inspiration, the head and shoulders are fixed, the spinal column is curved backwards, and all the muscles capable of producing upward movement of the bony cage are exerted to their utmost powers. In expiration after this effort the operation is reversed. The first to give way seems to be the diaphragm, the abdomen in spare subjects collapses, and then the ribs descend more gradually, beginning first with the upper ribs, and when a forced expiratory effort is required, the abdominal muscles are strongly contracted, the ribs, or even the scapulae, are pressed downwards, and the spine is pushed forwards so as to contract the cavity as much as possible. This seems to be the most frequent order of events, but it is important to remark that the action is undoubtedly greatly under the control of the will, and thus variations in the order of movement may be brought about by various causes—habit, disturbing emotion, suggestions from others, or antecedent ideas of what ought to take place. This fact may perhaps account for the different descriptions which have been given of the process by different observers." From this description it will be seen that Dr. Ransome's experience yields results which are directly opposed to the accounts of the most usual form of breathing in males given by Dr. Hutchinson and Dr. Humphry, and widely accepted as correct. The effect of inspiration and expiration on the spine, as stated by Dr. Ransome, is also directly at variance with the statements in esteemed text-books on Physiology. Thus, Huxley states: "In taking a deep inspiration the walls of the abdomen are relaxed, and become convex, the viscera being driven against them by the descent of the diaphragm—the spine is straightened, the head thrown back, and the shoulders outwards, so as to afford the greatest mechanical advantage to all the muscles which can elevate the ribs;" (a) whilst Dr. Ransome says that the spinal column is curved backwards in inspiration, and in expiration pushed forward, so as to contract the cavity as much as possible.

By the application of Dr. Burdon Sanderson's stetho-cardiograph during forced breathings, Dr. Ransome found that in men the fifth and sixth ribs rose before the second, whilst in females the difference in the time of rising was sometimes in favour of the upper ribs, sometimes of the lower. In tranquil breathing in the female there was apparent in every act of respiration a small precedence in the movement of the second rib.

The actual extent of the movements of the sternum and the ribs varied, according to Dr. Ransome's experiments, in different individuals, and in different regions of the chest. The sternum may be moved laterally as well as forwards and upwards. This may result from a natural difference in size between the two halves of the chest and the amount of muscular development, but it is especially obvious in cases of malformation, or disease of the thorax, congenital or acci-

(a) "The first rib is almost immovable, except in deep inspiration. The movement of the second rib is also not very extensive." (Gray's "Anatomy," p. 180.)

(a) "Elementary Lessons in Physiology." Huxley. Sixth edition, page 90.

dental. "As a general rule, the sternum moves forward, and sometimes upward, more freely than the clavicles, and the motions of the lower portion of the bone are greater than those of its upper end." I would suggest that the variation in the movements of the manubrium and gladiolus observed in different cases may be dependent upon the amount of mobility permitted at the upper sternal articulation, and upon the kind of joint existing there. A sliding joint with laxer ligaments than usual would permit the gladiolus to project further forwards than the manubrium. An ossified or rigid joint would entirely prevent such movement.

The motion of the *clavicles* is almost exclusively upward, and "they are especially affected by the final effort of breathing, when the extraordinary muscles are brought into action. The *ribs* at their anterior ends move more decidedly upward than the sternum," and their forward push, especially in the fifth and seventh, is very considerable. There is no regular increment of movement in the ribs as we descend from the upper to the lower, whilst there is abundant evidence of that independent action of the ribs which Dr. Hutchinson pointed out in certain chest diseases.

In a very large proportion of the male cases examined by Dr. Ransome, it was found that the movements on the right side of the chest exceeded those on the left, a fact which accords with the observations of Drs. Sibson, Wintrich, and Walshe, that in right-handed men the circumference of the right side may naturally exceed that of the left from one-half to three centimetres. The increased mobility on the right side is probably due to the greater force of the muscles on this side.

The movements of respiration in disease are on the whole much less extensive than those of health. In rare cases *increase* of movement, and especially of the upward movement, may be brought about by disease. This will also occur when, as Dr. Walshe says, "a muscular effort is made to overcome some obstruction seated low in the chest." The movements of individual ribs may be increased to compensate for decrease of movement of neighbouring ribs, and increased movement of one side of the chest may compensate for decreased mobility on the other.

*Decrease* of movements are exhibited to the greatest extent in emphysematous and asthmatic patients, the rigidity of the thorax in these disorders offering an almost equal impediment to all the movements of the ends of the ribs; but exaggerated costal motion will take place in ordinary enforced respiration.

One of the earliest indications of phthisis both in males and females is a diminution of movement over the part immediately affected, the forward push being more retarded than the upward rise.

The dimensions of the Thorax differ in the two sexes, and at different periods of life. In the female the Thorax is shorter and wider than in the male, allowing more room in the Abdomen for the exigencies of pregnancy and parturition. The foetal Thorax is remarkable for its great expanse inferiorly, due to the large size of the liver at this period of life; for its extreme shortness from above downwards, owing to the non-development of the Sternum; for its contraction from side to side, arising from the want of expansion of the lungs, and for its depth from before backwards, depending upon the large size of the Thymus gland and the greater comparative magnitude of the Heart. These several peculiarities give to the foetal chest a striking similarity to the same cavity in those animals where a want of the clavicle exists—viz., its flatness from side to side and its equally striking antero-posterior depth; but as the lungs expand and the Thymus gland becomes gradually atrophied, the Ribs by degrees assume their rounded form, and their angles begin to make their appearance, while the Sternum, hitherto so prominent, now commences to recede. The upper aperture, too, still continues of an oval shape, but its long measurement is from the same cause gradually changed, being no longer from before backwards but from side to side; while the inferior, owing to the diminished size of the liver, as contrasted with what it was at birth, is no longer conspicuous for its relatively vast circumference. (a) The increase in the transverse diameter of the chest continues throughout life. In children the chest walls move relatively to a greater extent than in adults. The bones are more mobile, and the cartilages are more elastic. As old age supervenes, the elasticity of the cartilages is impaired by advancing ossification, the joints grow rigid, a preternatural elevation of the ribs results from over-distension of the air-cells of the lungs,

which have lost their resiliency, and are unable adequately to expel the air in expiration, the movements of the osseo-cartilaginous hoops become more limited, and the business of respiration is mainly discharged by the Diaphragm. Old persons are peculiarly liable to suffer from that over-distension of the air-cells of the lungs which is called *Emphysema*. It causes the intercostal muscles to be pressed outwards and the chest to become barrel-shaped. Variations in the shape of the Thorax are of practical interest to the medical practitioner, because they indicate the state of the Lungs. Accustom yourselves to observe the shape and movements of the chest in the patients who come before you. Much important information may thus be gained. Mr. Ward observes on this subject: "The capacity of the thorax indicates the volume of the lungs, which usually bears a direct proportion to the development of the muscular system and the general vigour of the body. An expanded chest is the sign of sound health; a narrow, contracted chest, with a prominent sternum, indicates an inherent weakness of constitution, and is frequently accompanied by a consumptive tendency. Besides these congenital diversities in the shape of the thorax, the student will meet in the dissecting-room with others which are produced by artificial means during life. For an example of these we may refer to the distortion which is caused by wearing a tight bandage round the middle region of the body. This practice, which reduces the expanded lower circumference of the chest to two-thirds of its natural size, and impairs to a dangerous extent the functions of digestion and respiration, prevails among the females of several European nations, who prefer an abrupt indentation of this part of the body to the flowing curve of the natural outline. So highly, indeed, is this unsightly deformity esteemed, that the thorax is often subjected to compression at an early age, before the bones are firmly knit, in order the more effectually to force in the lower ribs on the abdominal viscera." (a)

The natural expansion of the lower part of the Thorax is specially needed to afford a firm attachment to the Diaphragm, and to counteract its tendency to draw inwards the cartilages of the six lower ribs. Forcibly to press them inwards is to imitate those deformities of the Thorax which result from a want of power in the muscles, which draw the lower ribs outwards, or from insufficient expansion of the Lungs in this region. Any cause which prevents air from entering the chest—obstruction from enlargement of Tonsils, disease of the Larynx or Lungs—may give rise to lateral depression, either temporary or permanent, or to the deformity commonly known as "chicken breast," or "pigeon breast." In this distortion the Sternum and the Costal Cartilages form an unnatural projection, the distance between the Sternum and Spine is increased, the Ribs are bent inwards at their junction with their Cartilages, and a furrow exists externally at the same point. The action of the Diaphragm tends to increase the deformity, and the curious phenomenon may be exhibited of contraction of the transverse capacity of the chest in inspiration and its enlargement in expiration.

(To be continued.)

## Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

MONDAY, NOV. 30TH, 1874.

MR. J. ASTLEY BLOXAM exhibited a boy 10 years old having a dislocation of the patella, which had existed five years. There was no pain, only a slight feeling of weakness. The dislocation occurred every time the knee was flexed, reduction taking place with extension. This, Mr. Bloxam remarked, was contrary to what is said in books on the subject. The patient's family was generally affected with rickets.

The PRESIDENT stated that he had seen this patient at the Royal Free Hospital once, but had not been able to make up his mind with reference to the line of treatment to be adopted. He should like to hear the matter fully discussed by the Fellows.

MR. WM. ADAMS considered the case rare and interesting, being one of dislocation of the patella accompanied with

(a) "Human Anatomy," Ledwich, p. 25.

(a) Ward, "Human Osteology," p. 209.

only slight knock-knee, this lesion being generally associated with a marked degree of knock-knee. Dislocation of the patella seldom caused synovitis among children, because it was a slow process, and the result not of an accident, but of a loose condition of the ligaments and the surrounding tissues. He remembered an instance of a young gentleman who had both patellae dislocated, and was thus rendered lame. He recommended the knees to be kept extended in leather splints for one or two years, and he entirely recovered the use of his limbs, and was able to do without any appliance.

Mr. DAVY said he knew no cases so difficult to manage as these, and related a case of a man, *æt.* 40, on whom a splint was used for a whole year, and on its removal the deformity returned as badly as ever. Mr. Adams' mode of treatment was far more successful in the cases of children than in adults. At the Surgical Aid Society a laced knee-cap was generally made use of, though Mr. Davy considered that some mode of appliance by which the action of opposing muscles could be equally balanced was highly desirable.

Mr. BLOXAM also exhibited a patient, a woman, from whom he had removed the zygoma and styloid process in the extirpation of a cystic sarcoma. Nine years previously Mr. Hulke had excised half the lower jaw for the same disease. During the operation Mr. Bloxam had to tie the external carotid artery and the internal jugular vein, both of which were divided. He pointed out the peculiarity of the growth returning after such a lapse of time.

The PRESIDENT said the case exemplified the wonderful depth to which operations about the jaw might be carried. He recollected a case where the basilar process was reached. In this case of Mr. Bloxam's he was surprised that no septicaemia had taken place.

Mr. LEIBREICH remarked that the want of occlusion of the eye observable in this case was due to two causes—(1) the destruction of the seventh nerve and the orbicularis muscle; the eye could only be protected by turning it upwards; (2) the destruction of the fifth nerve, causing loss of sensation of the conjunctiva, followed by cornæitis and ulceration. There was no doubt that cataract had formed. He considered that the eye should be completely closed by stitches, forming an artificial symblepharon, as a means to prevent further destructive changes.

Mr. BLOXAM said cataract had formed, and extensive paralysis of the fifth and seventh nerves had taken place since the last operation.

Mr. HENRY SMITH then showed a specimen of excision of the knee-joint, remarkable for the fact that when first admitted the patient seemed to have little or nothing the matter with him. After a while he complained of great pain and starting of the limb, and Mr. Smith diagnosed ulceration of the cartilages of the knee-joint, operated, and obtained a very favourable result. His experience was against operating when the synovial membranes were extensively diseased; but only in cases where the cartilages and bone of the joint were only partially affected, and no constitutional symptoms present.

Mr. R. DAVY narrated seven cases of excision of the knee-joint operated on by him in the Westminster Hospital. In cases Nos. 4 and 7 sinuses yet existed. Necessarily shortening of the limb occurred in every case; but all the patients can walk with the aid of a high-heel boot, and the improvement in health and the reduction in deformity has been marked. The average stay in hospital of the patients has been 82 days, contrasting favourably with 208 days' stay of other excision cases (*vide* Holmes' "Surgery," vol. iii., page 822). The author found Esmarch's bandage a great boon in these operations. The transverse incision over the line of articulation is strongly enforced, the ends of the femur and tibia projecting (on forced flexion) like the muzzle of a double-barrelled gun. Especial care is given to the posterior ligament of the knee-joint, as it acts as a hinge to the two bones. The author slices off the ends of the bones until accuracy of adaptation results in a straight line. Sutures of stout silver wire are used, restrained by large shot, or lead tubes. No dressings whatever are requisite, but to brush the wound over with a weak solution of Condy's fluid, or carbolic acid, and attend to the temperature of the ward, and enforce surrounding cleanliness. The cases were illustrated by four of the children, who were present, also by casts, splints, splintage instruments, &c., and the bone removed at the operation. Mr. Davy attributed the success which had attended the results to Esmarch's

bloodless plan as adopted at Westminster Hospital to the simplicity of the after-treatment and to the stern enforcement of maintained rest.

The PRESIDENT, after alluding to the elaborate way in which Mr. Davy had worked out his cases, remarked that great confusion existed in the use of the terms excision and resection, and thus the difference between Mr. Holmes' and Mr. Davy's statistics might be explained. The term excision should only be applied when all the articular surfaces are carefully removed, and this was generally done only where grave disease of the joint existed. Many of Mr. Davy's operations were performed on cases of more or less deformity of the joint without serious disease.

Mr. BLOXAM alluded to the absence of death in Mr. Davy's cases, and called to mind 17 instances of excision, many of which resulted fatally. In some the operation was insufficient, and amputation had to be performed at a later date. It was not fair to compare these cases of joint deformity, where the symptoms were quiescent, with the usual run of hospital cases for which excision was performed.

Mr. HOLTHOUSE bore witness to the great skill of Mr. Davy as an operator, but thought, with the preceding speaker, that no comparison could be made between Mr. Holmes' and Mr. Davy's statistics. He disapproved of the after-treatment, especially the non-removal of the dressings, as the entire absence of cleanliness and the presence of heat and damp furnished all the elements of putridity, and surrounded the patient and the other sufferers with a most unhygienic atmosphere.

Mr. DAVY agreed that his were favourable cases, but thought they were of a character to demonstrate that the operation might be safely extended in practice. Mr. Holthouse's argument pointed, not to a discontinuance of his mode of dressing, but to greater care being exercised by the nurses and attendants in its application.

MONDAY, DEC. 7TH, 1874.

Dr. SANSOM, Vice-President, in the Chair.

Mr. ROYES showed for Mr. Henry Smith a boy born with a hare-lip, and cleft soft and hard palates, who had been operated on according to Sir Wm. Fergusson's plan with considerable success.

Mr. WM. ALLINGHAM exhibited

A SCIRRHOUS TUMOUR OF THE BREAST REMOVED FROM A WOMAN, *Æt.* 64, BY THE ELASTIC LIGATURE.

Needles had been introduced in the ligature applied, without pain and without anaesthetics. The process took seventeen days, was unaccompanied by any rise of temperature or other unfavourable symptom, and the patient made a complete recovery.

Mr. NAPIER inquired what kind of india-rubber was used.

Mr. THOMAS BRYANT condemned the use of the ligature in ordinary surgical practice, though in exceptional cases, as when the patient was hæmorrhagic, he did not object to it. The operation was tedious, lasting in this case seventeen days, when removal by the knife would have taken seventeen seconds; besides, it had the disadvantage of retaining a mass of almost putrid matter in close connection with the body, giving rise to the danger of septicæmia. It was true the patients did not complain of severe pain, but they underwent a considerable amount of chronic suffering.

Mr. CARTER asked why ether was not used. He was under the impression that its use was unattended with risk, and that no deaths had occurred from this cause.

Dr. THEODORE WILLIAMS was surprised at Mr. Carter's question. A reference to the Report of the Committee of the Medico-Chirurgical Society on Chloroform and Anaesthetics would show him that there had been several deaths from ether, and during the experiments on animals several dogs were killed by ether, as by chloroform, it being only a matter of dose to effect this result.

Dr. SANSOM said deaths from ether had been recorded by Trouseau and other authorities.

Mr. ALLINGHAM, in reply, said that the patient, being of a very delicate constitution, was unfitted for operation by the knife, while india-rubber was used, and the wound being freely dressed with carbolic oil and other antiseptics, no

putridity existed. He knew a medical man who had been operated on by both methods—knife and ligature—and he greatly preferred the latter as being without pain.

Dr. ROUTH then read a paper on

#### AN EPIDEMIC OF INFECTIOUS SORE-THROAT

which occurred in a public institution, and the probable causes of its production. After a proper tribute to Dr. Farquharson, who had preceded him last session on a subject analogous to the present, the author first gave a description of the institution and its sanitary appliances, where every means had been taken to secure ventilation and a good supply of water and food, and also the unexceptional cleanliness of the girls who were the inmates. Effective means were likewise always at hand in case of infectious disorders arising, and great care taken to prevent as far as possible their introduction. One case of typhoid fever occurred in October, 1873. The patient was removed to Middlesex Hospital, and ultimately died there. This was after the return of the inmates from the sea-side. On the introduction of a new matron, a little while after, the sore-throat disease broke out synchronously with measles and erysipelas. The appearance of measles was explained by the inmates occupying seats in an ill-ventilated church, where a school, then seriously affected with this epidemic, had been sitting in the morning. One of the erysipelas cases was subject to the disease; but all the others occurred when the throat epidemic was at its height. One died suddenly, with symptoms of sickness and exhaustion. The sore-throat epidemic (of which there were 46 cases) exhibited three types—simple cynanche, diphtheritic patches, and scarlet fever. When Dr. Routh left London, in September, all the sanitary appliances were reported, on inspection, to be in good order. The scarlet fever cases occurred when in the charge of Mr. Cheyne. Then, on inspection again being made, the water was found impure, and the filter, having been meddled with, was no longer effective; the drains in the garden were said to be offensive. One fact was noted—of the six matrons, it was the one who drank water only who was affected with severe cynanche. Of the six monitors, all escaped except one, and she also was a water-drinker. Dr. Routh then proceeded to show that other sources of infection had not been disregarded—(1) from visitors; (2) from infection at the sea-side. But on full inquiry being made, no such infection was traced. He concluded in urging for discussion—(1) Were the three diseases of the throat coexistent, but different affections, or the same disease? (2) Was the erysipelas produced by a similar miasm? (3) Can the sewage-tainted water have produced the disease, notably the scarlet-fever? (4) Had the typhoid fever, then prevailing in London, any influence in the production of this epidemic?

Dr. HAVILAND HALL was sure that bad sewage might give rise to various forms of disease, and cited an instance where peritonitis and erysipelas arose from an escape of sewer-gas in a public institution.

Dr. FARQUHARSON was of opinion that the first class of Dr. Routh's cases had nothing to do with the last class, and were quite distinct.

Mr. BRUDENELL CARTER thought the paper admirably demonstrated the perils of water-drinking. He always told his teetotal friends that, until they could guarantee to society a pure specimen of the commodity they so highly prized, instead of the present often dangerous mixture, they had better cease preaching the gospel of water.

Dr. CRISP, as a water-drinker, replied that human life was curtailed at least ten years by the use of alcohol. As illustrating the connection between diphtheria and sewage, he gave an instance of a house in Devonshire, where nine children died within a month from a species of diphtheria, quite unknown in the neighbourhood. On investigation the drainage of the house was found to pass into a pond, the water of which the children drank.

Mr. CHEYNE had charge of Dr. Routh's cases in his absence, and distinguished three forms of disease—(1) a pure scarlatinal case; (2) cases of sore-throat devoid of rash or high temperature; (3) cases of erysipelatous sore-throat. The drinking-water was the only cause of disease, which could be demonstrated, as no proof of contagion existed.

Dr. BUCHANAN, in support of Mr. Carter, asked Dr. Crisp if he ever knew of nine children dying of alcohol in one house, as occurred in the melancholy instance in Devonshire. He set a high value on Dr. Routh's careful and elaborate paper, and noticed that the gap of fourteen days which

intervened between the first and second batches of cases precluded any idea of infection. He had no doubt that both scarlatina and diphtheria had appeared in the Home, and that they prevailed together he was certain. Some of the cases had evidently nothing to do with either of these diseases, but must be classed with the erysipelas which appeared on the scene. He thought that a form of sore-throat of the same character as the well-known hospital sore-throat, but non-specific in kind, might and did arise from septic causes, such as the presence of putrid matter. As for the exact source of this epidemic, it appears to be traceable to sewage. The institution being flooded with sewer inhalations, instead of the ventilation described purifying the air, it probably assisted in freely diffusing the sewer-gas through the building. There being two methods of infection in this instance, the water and the air, it was difficult to distinguish which was the agent; but that the erysipelas might arise from septic matter dissolved in water ample evidence existed. In the epidemic outbreak at the Patriotic Asylum last autumn, erysipelas came on, followed by a curious form of peritonitis, which the late Dr. Anstie thought he traced to water-poison.

Dr. THEODORE WILLIAMS inquired the amount of cubic space allowed per head in the building, and whether natural ventilation was relied on, as, if it were, there was little chance of keeping a crowded institution pure and wholesome. He had no doubt of the existence of sore-throat, non-specific in character, and arising from septic causes, and had noticed instances of it, occurring chiefly among servants who occupied the basement of houses, and therefore were in closer proximity to the drains.

Dr. ROUTH, in reply, said that both the beginning and the ending of the epidemic were characterised by erysipelas, and that notwithstanding all that had been said—and he was much obliged to the Society for discussing the matter so thoroughly—he saw no case made out for attributing the disease to anything else than poisoned water. In conclusion, the treatment consisted of effervescing salines, gargles containing chloride of potash, and the local use of tannin.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 16, 1874.

#### DR. LETHEBY AND HIS CRITICS.

It will be remembered by our readers that at a meeting of the Society of Medical Officers of Health of London, on the 17th of October last, Dr. Letheby, the President, delivered an address "On the Comparative Salubrity of Towns," wherein he showed that, from the immense migration which takes place of young adults from country parts into towns, the death-rate of the rural district where the young persons have been reared is unfairly augmented, while that of the towns is proportionately reduced.

In London, said Dr. Letheby, the death-rate of infants is so large that not more, and probably much less, than 60 out of every 100 born live to be 20 years old. At this rate, the 296,929 young adults who were added to the population of London during the last 20 years would, if they had been produced here, have cost 494,872 births, and 197,949 deaths, not one of which had appeared on the registers of the metropolis. An examination will show that nearly half the population of London are aliens, and have migrated into it from the provinces, perhaps at the rate of some 32,000 a year.

There are only, he added, 263 children per 1,000 of the population of London, as against 356 in all England; but the number of young persons, at from 15 to 35, is very large. In the City proper it amounts to 415 per 1,000; and is 360 per 1,000 in the whole metropolis, as against 335 in all England and Wales.

In the heart of the City the number of women at from 15 to 55 years of age amounts to 337 per 1,000 of its inhabitants, and in the rest of the metropolis it is 315 per 1,000, although for England and Wales it is only 280 per 1,000.

Up to the age of 10, said Dr. Letheby, and after the age of 25, in the case of males, and 35 in that of females, the death-rate in London is much greater than it is in all England; but at the intervening ages, from 10 to 25, and 10 to 35, the death-rate in London is much below the average, showing that persons of those ages go away from London when sick.

The gain to London is hence threefold. In the first place, the population is continually receiving a large number of adult lives without the vital cost of producing them; it gains by the substitution of such lives for the weak and ailing; it gains by the fusion of such lives of high value with the general mass of the population of comparatively low value.

Whenever the birth-rate, said Dr. Letheby, is high, the death-rate is high also. France, with a birth-rate of only 26.26 per 1,000 of her population, has a death-rate of only 23.63 per 1,000; but Austria, with a birth-rate of 39.86 per 1,000, has a death-rate of 30.34. In the south-western division of England the birth-rate is only 32 per 1,000, and the death-rate less than 20 per 1,000; in the north-western division the birth-rate is 39 per 1,000, and the death-rate 26.3. As a general fact, in England, it is found that, when the birth-rate is from 30 to 31 per 1,000, the death-rate is about 19; and when the birth-rate is about 35 to 37 per thousand, the death-rate averages 24.4.

We must say that we hold that Dr. Letheby was perfectly right in most of the conclusions he drew from the above figures we have quoted from his vigorous and convincing paper. The common-sense view of town life surely has always been that it is very much less healthful than life in the purer air of the country; and all medical men of observation must have frequently, like Dr. Letheby, been in the highest degree sceptical as to the supposed healthiness of London as proved by its death-rate.

Mr. Malthus found, in his well-known work, written near the commencement of this century, just what Dr. Letheby assumes as proved—namely, that wherever in any European State the birth-rate is very high, there will the death-rate be found very high. Norway and Switzer-

land—and in modern days, France—are the countries which have been often alluded to as examples of the fact that rapid multiplication results in a high death-rate, and Dr. Letheby deserves the best thanks of the medical profession for his protest against the vain-glorious boastings of the responsible writers of the Census Office, who would have the inhabitants of this civilised country believe that there is something quite providential in the over-crowding and squalor of our large centres of industry, over-peopled and miserable as they are.

We notice that Dr. Letheby's paper has drawn forth a very severe and warlike epistle from the gentleman who is the head of the statistical department in Somerset House. In a letter, signed George Graham, and directed to the secretaries of the Society of Medical Officers of Health, the Registrar-General observes that, as he understands that at the monthly meeting of the Society of Medical Officers of Health, on the 17th of October, the President stated that the reports published by his department were untrustworthy and ridiculous, and thought by some to be threatening to become a public nuisance; and as he furthermore learns that Mr. Hawkey, C.E., remarked that they were erroneous, not worth the paper they were written on, and full of mischievous fallacies, whilst not one dissentient voice was raised to contest the above statement, he, the Registrar-General, begs to have his name erased from the list of members of the society.

There is a final paragraph in the letter, to the effect that gratis copies of the Weekly Reports will no longer be supplied to a society which is presided over by Dr. Letheby, M.B., M.A.; but that any member of the society who does not agree with the President will be able to purchase the Reports for the sum of one penny at the Queen's printer's every week.

*Tantene animis cælestibus ire?* Why could not Major Graham listen to criticisms on public documents with more equanimity? He is not responsible for the figures in his reports, and only shares the fate of all authors, when he publishes (at the national expense) lucubrations of his own concerning political economy and other studies, which he takes the liberty, we must think, to evolve from the depths of his own consciousness. We have not the census of 1861 or of 1851 before us, but remember to have sighed bitterly to think that men placed in such important situations as he should have so misinterpreted the teachings of Ricardo, J. B. Say, Garnier, and the two Mills. It was a sad thought to us, that the country that had given birth to the greatest thinkers on political economy the world has ever known, from Adam Smith and Malthus down to J. S. Mill, should have as official teachers of the uneducated part of the nation men who seemed to set at nought all the experience of the best and ablest writers. Even the death-rate in London and all England would be more complete than it is if still-births were registered, which is done in France, Belgium, and Holland.

There was an article on the Registrar-General's side, in one of our medical contemporaries, on October 31st, which was followed by another in the same paper on November 7. In these articles, evidently inspired by the Registrar-General's office, it is conceded that the crude death-rate in towns understates the mortality. But, as far as we know, it adds, the understating does not exceed 3 or 4 per 1,000.

The article goes on to say, "this is not considerable, when we find the death-rate of 30 years (1841-70) varying from 15 in Glendale, Northumberland, to 24 in London, 27 in Birmingham, and 36 in Liverpool. Add 2 to Glendale, 3 to London, 3 to Birmingham, and 3 to Liverpool, and the mortality, corrected approximately so as to make it the mortality of a population normally constituted as to age and sex, becomes 17, 27, 30, and 39."

We cannot see on what principle 2 is to be added to Glendale and only 3 to London. According to *a priori* considerations, it would seem as if a very great number of units ought to be added to the corrected mortality of London to make it likely to be comparable with the health of a well-fed and high-class country district like Glendale, the land of the *Statesmen*, so often celebrated in the poems of Wordsworth.

In the second article on Dr. Letheby's paper, to which we have referred, there is this passage. "The pertinacity with which Dr. Letheby clings to his axiom that the birth-rate is the controlling element of the death-rate is worthy of a better cause, but is, at the same time, the strongest evidence of his reluctance to believe that he can be wrong. The proportion of infants under one year of age in a population varies, according to the birth-rate, only between about 25 to 35 in a population of 1,000; it follows, therefore, that, so far as this age is concerned, any influence upon the death-rate of the whole thousand which the birth-rate exercises is confined to the extreme differences of about 10 infants. All children under 5 years of age do not average more than 100 per 1,000, whereas the proportion of persons aged 60 and upwards averages about 126. As the rate of mortality among children under 5 years is lower than among persons aged 60 and upwards, it follows that the average rate in 1,000 depends fully as much—nay, more so—on the proportion of elderly persons as upon that of infants."

Can it be supposed by the writer of the above that the facts quoted by Dr. Letheby are met by such an argument as this. If so, let him only remember that, whenever the death-rate of infants is high, the death-rates at every age are high. An excellent example of the truth of this well-known law is to be found in the most useful tables published this year by Mr. Ansell, jun., Actuary to an Assurance Company.

Dr. Letheby is, we affirm, far nearer truth than the Registrar-General. It is, indeed, difficult to arrive at accurate conclusions from statistical facts. These facts require to be read by persons familiar with deductive reasoning on social questions; and neither Major Graham nor Dr. Farr seem hitherto to have grasped the salient points alluded to by Dr. Letheby, that town life is far more unhealthy than the death-rates show.

Reasoning from our own ordinary observation among the hospital population of London, we should say that the difference of health and longevity between Londoners and well-fed country folks must be at least some 20 years, if not more. The hosts of cases of rickets seen at our children's hospitals, the sad *cortège* of consumptives which haunt our Brompton Hospital, &c., are to our mind a clear proof that the picture given of the health of London as compared with a country side where wages are decent is immensely coloured.

Happy the land where towns are few and far between. Vigour and enjoyment of life flow from pure air and out-of-door employments. Let statistics be interpreted even by Dr. Farr and Major Graham, nothing will convince us to the contrary.

## THE ACTION OF DRUGS.

### VI.

WE have yet another column to consecrate to the actions of atropia and morphia as determined by the Edinburgh Committee. We proceed, therefore, to conclude this part of the subject by continuing our analysis from where we left off last week.

In the next experiment two and a half grains of meconate of morphia and 1-12th of a grain of sulphate of atropia were injected simultaneously, the respiration and cardiac pulsations being found to average—respirations 28 per minute, cardiac pulsations 132 per minute, while the pupil measured 7-50ths of an inch at the commencement; but after sixty minutes it was found (1) that the respirations had fallen from 23 to 16, and were deeper and more prolonged; (2) the cardiac pulsations had risen from 140 to 231, and were for a time very powerful, but afterwards became so weak as scarcely to be felt; and (3) the pupil became contracted, but not nearly to the same extent as would have been produced by the meconate of morphia alone. Professor Bennett thus sums up:—

"These results indicate a mutual action between the meconate of morphia and the sulphate of atropia. Meconate of morphia, when given alone, depresses both the cardiac pulsations and the respirations, and contracts the pupil. Sulphate of atropia, when given alone, slightly depresses the respirations, greatly accelerates the cardiac pulsations, and dilates the pupil. When both are given together, as in this experiment (Table xxxiii.), the respirations were reduced in frequency, indicating a preponderance in the effect of meconate of morphia; the cardiac pulsations were increased, indicating a stimulant action on the heart produced by the sulphate of atropia; and the pupil was slightly contracted, indicating that, with respect to this structure, there was nearly a balance as regards physiological effect between the two substances, but the influence was in favour of the meconate of morphia. It is also to be observed that the acceleration of the cardiac pulsations was not nearly so great when both substances were exhibited, as when sulphate of atropia, *even in smaller doses*, (*italics ours*), was given alone (see remarks on the physiological action of sulphate of atropia on dogs, *Journal*, October 24th, page 519).

"The dog in this experiment died at the end of three hours and a half. It gradually became more and more deeply comatose. There was no evidence of any delirium. Reflex action gradually became more and more feeble; the respiratory movements were fewer and more and more shallow; the cardiac pulsations became so weak as scarcely to be felt, but they were still rapid, and at last the animal died without any convulsive seizure. The lungs were much congested, and there was fluid in the pleura."

In Experiment 376 the same dose of morphia is given, but with a quarter of a grain of atropia. The animal died in six hours, and it was observed that the cardiac pulsations were for a longer time more rapid and stronger.

In Experiment 377 the same dose of morphia is given, and one-third of a grain of atropia. This animal died in eight and a half hours, and in the same condition of profound coma as in the last two experiments.

In Experiment 378, to a dog weighing 14 lbs., 2½ grains

of morphia and two-thirds of a grain of atropia were given, and this animal, after remaining in a state of stupor 6½ hours, slowly recovered; and ten days after, the dog now weighing 13½ lbs., was killed by the same dose of morphia. This was repeated on another dog, weighing 13½ lbs. (Experiment 379), with same result, viz, recovery after 2½ grains of morphia given with two-thirds of a grain of atropia, and death several days after when same dose of morphia was given alone. The report thus concludes:—

"It appears from the above experiments, that in dogs sulphate of atropia modifies the symptoms of poisoning by meconate of morphia, diminishes their intensity, and may even save life after a fatal dose of the latter. It is therefore decidedly antagonistic, but within a limited area. In man, sulphate of atropia would be too dangerous and uncertain a remedy to depend on in cases of poisoning by opium or any of its salts, but where the heart's action is greatly diminished it is directly indicated. (a)

Referring back, we find that Professor Bennett has already told us (Experiments 372, 373) that in rabbits the time of death seemed to be rather hastened than delayed when atropia is given with morphia, especially if the dose be large, although he concludes that atropia given after morphia may reduce the risk of death from cerebral or spinal congestion, by its power of contracting the blood-vessels, and may also stimulate the action of the heart through the sympathetic. Bearing this in mind, let us review the experiments on dogs recorded above.

In Experiment 375, a dog weighing 12 lbs. recovered after receiving two grains of morphia, and in Experiments 378 and 379, the dogs weighing respectively 14 lbs. and 13½ lbs., recovered after receiving 2½ grains of morphia with 2-3rds of a grain of atropia, and were killed ten days after by the same dose of morphia given alone (the weight of the dog in Experiment 378 having, however, fallen from 14 lbs. to 13 lbs.). It does not at all follow that the animals would not have recovered from the 2½ grains of morphia without the aid of the atropia, for, allowing weight to have any influence on the effect, we might naturally expect that, if a dog weighing 12 lbs. recovers after 2 grains, one weighing 14 lbs. might recover after 2½ grains. The fact of their being killed ten days after by the same dose is no satisfactory proof that 2½ grains of morphia is the minimum fatal dose for a dog weighing 14 lbs., because we are furnished with no experiments to show (as in the case of rabbits) what is the exact minimum fatal dose for a dog of that weight. The animals had been nearly killed ten days previous with morphia and atropia, and we cannot much wonder that they succumbed to the 2½ grains of morphia, especially when one had fallen off in weight from 14 lbs. to 13 lbs.; and referring back to Experiments 306 and 307, we see atropia does not tend to improve an animal's health, for in Experiment 306, 1-80th of a grain was given to a dog weighing 16 lbs., and ten days after the same animal only weighed 13½ lbs., and was out of condition. Such being the case, we are very reluctant to believe that in Experiments 378 and 379 the animals recovered after 2½ grains of morphia because 2-3rds of a grain of atropia was given, or that 2½ grains is the minimum fatal dose because they were killed ten days

after by morphia alone. We only regret that the experimenters did not ascertain the minimum fatal dose in this case in the same careful manner as they have in former cases.

We must say these experiments fail to shake our faith in Dr. John Harley's conclusion, and we would be very reluctant to depend on atropia alone as an antidote to opium or its salts, although we might avail ourselves of its stimulant action (in small doses) on the heart, and use it in conjunction with other means.

## Notes on Current Topics.

### Private Asylums in Ireland.

THE condition of private asylums in Ireland is the subject of comment by the inspectors in their recently issued report. On the 31st of November, 1872, they amounted to 645. At the like date in 1873, to 644. The admissions last year consisted of 88 males and 89 females. So far indicating the proximate rate of insanity between both sexes in the better classes of society. Taking the inmates of private asylums at the close of 1872, and those admitted in the subsequent twelvemonth, independent of Chancery patients and others elsewhere in private families, 822 were under treatment and subject to our official inspection and examination. Of these 126 were discharged—65 as cured, and 37 improved.

The recoveries speak favourably, being a full average on admissions and previous residents, at the same time that the mortality, not quite 4 per cent. on the whole under treatment, is little over that among the general public.

The inspectors say that with reference to the interior organisation of licensed houses, some institutions are materially in advance of others; and, indeed, it could not well be otherwise, when it is borne in mind that while in some establishments from £100 to £300 is allowed for patients, in others the stipends are not half so much, often too irregularly paid.

Looking to the general working of private licensed houses in this country during the past year, we are gratified at being enabled to report that not a single cause of complaint sufficient to need an official inquiry was preferred to the executive or to the inspectors; neither was there an instance of improper detention.

### Lead Amaurosis and Aneurism.

DR. THOMAS REID, of Glasgow, brought before the Glasgow Pathological and Clinical Society, recently, a man, aged 36, with blue line on the gums and with defective vision of left eye. There had been slight hemiplegia affecting the left side, after partial insensibility. Under iodide of potassium the vision was improved so that he could read Jäger No. 1, but the field of vision was still contracted. The ophthalmoscope showed the left disc to be oval, with the long axis vertical, pearly-white, with vessels diminished in calibre. There seems only to have been a supposition that this was a case of lead amaurosis. In the same society, Dr. Foulis, on Nov. 10, showed a specimen of aneurism opening into the spinal cord, re-

(a) In Experiments Nos. 376, 377, 378, and 379, the number of cardiac pulsations and respiratory movements were not counted, nor the pupil measured, as the object was to see whether or not life could be saved after a fatal dose of meconate of morphia.

moved from a patient of Dr. Gairdner's, aged 37. The history of the disease dated two years back; but the nervous affections were but of two months' duration. Shooting pains in the legs, followed by weakness, and ultimately complete paralysis and anæsthesia of the lower limbs, with retention of urine and obstinate constipation, were present. There was intense pains over the fifth and sixth dorsal spine, extending round to the cardiac region; a systolic *bruit* was audible at the apex of the heart; there was only a subfebrile elevation of temperature. Ultimately bed-sores came on, and difficulty in micturition. Whilst in hospital the bowels only acted under strong galvanic stimulation, and vomiting and retching were troublesome. At the autopsy the walls of the bladder were found in a state of slough, and the ureters and pelvis congested, and coated with muco-purulent matter. A small tumour was found on the right of the aorta, springing from its posterior part, opposite the fifth dorsal vertebra, partly occupied by coagula and laminated clot, and a few loose specula of bone. It had destroyed the body of the fourth and sixth dorsal vertebra, and extended into the spinal canal. The spinal cord was rather soft below the aneurism.

### The Expenditure of Irish District Lunatic Asylums.

The expenditure for the maintenance of Irish district asylums was larger during the last year by £13,181 than in the preceding—a circumstance admitting of a twofold explanation, the daily average of patients and servants in 1873 being 204 greater than in 1872, while the cost of many articles of consumption, but especially of coal, so largely used, was exceptionally high. If to the maintenance, £13,814 5s. 2d., presented for by grand juries at the Spring Assizes, and £14,931 3s. 7d. at the Summer Assizes, be added as the annual repayments for building advances from the Treasury, the full outlay levied off the country will have been £216,271 in the past year. The average cost of maintenance for the year under review was £25 10s. 2d., as compared with £23 16s. 7d. during the preceding year. The higher rate is clearly traceable to the large increase in the price of articles in daily consumption which took place.

### Preservation of Vegetable Infusions by Chloroform.

MR. J. B. BARNES has recently communicated some interesting experiments made in his laboratory upon the preservative effects of chloroform. He finds that infusions of calumba, chiretta, malt, and senna will keep good for a reasonable time by adding *five* minims of chloroform to every eight fluid ounces; and *three* minims will suffice to preserve the same quantity of infusion of roses. It will be easy to add chloroform to concentrated infusions, so that when diluted, each sixteen ounces may contain *ten* minims of chloroform. He also tried the effects upon two samples of mucilage of acacia, in the proportion of *one* and *two* minims respectively, to the fluid ounce; after six weeks both appeared to be as fresh as on the day they were made.

At the same time *four* minims of chloroform were added to four fluid ounces of mucilage of tragacanth, well agitated

and set aside, together with some of the same mucilage without chloroform, which, when tested immediately after it was prepared, proved neutral to litmus. These samples were again tested a few days after, and that containing chloroform was still neutral, whilst the other had become strongly acid, and quite unfit for use.

Mr. Barnes is of opinion that the preservative effects of chloroform act on the fermentable substance held in solution, which is strengthened by the property it possesses of preventing alcoholic fermentation.

Not only is the alcoholic fermentation prevented by chloroform, but when added in sufficient quantity to fresh milk, the lactic fermentation is also prevented. To two eight fluid ounces of fresh milk was added respectively, *ten* and *twenty* minims of chloroform: they were kept in a warm place, and occasionally agitated; after five days had elapsed, that containing *ten* minims had developed lactic acid in quantity sufficient to separate the caseine, whilst that containing *twenty* remained fresh and good. It might be found convenient to preserve milk in this manner, always taking care to boil it just before using, in order to drive off the chloroform.

The author, in conclusion, thinks it is very probable that solutions of acetate and citrate of ammonia, citric acid, lemon juice, and many other organic substances, may be preserved by chloroform.

### New Books for the Month in Medicine, Surgery, and Science.

(From the Bookseller.)

ARCHIVES of Ophthalmology and Otology. Edited and published in English and German by Profs. Knapp and Moos, M.D. Vol. IV. No. 1. New York. 7s. 6d.

Carpenter (W. B.), Mental Physiology. 2nd ed. 12s.

Davis (M. S.), Clinical Lectures on Various Important Diseases. 2nd ed. 9s.

Flint (A., jun.), The Physiology of Man. In 5 vols. Vol. V. New York. 22s.

Frey (Heinreich), The Histo-chemistry of Man. A Treatise on the Composition and Structure of the Human Body. Translated from the German by Arthur E. J. Barker. 21s.

Gunn (Dr. R. A.), Venereal Diseases. New York. 12s.

Hammond (W. A.), On Diseases of the Nervous System. New York. 18s.

Hartshorne (H.), Principles and Practice of Medicine. A Handy Book for Students. 4th ed. Philadelphia. 14s.

Hooker (W.), New Physiology. Text-book for Institutions of Learning. New York. 8s.

#### Small-pox among the Kalmuck Tartars.

NOWHERE, says the *Golos*, does variola make equal ravages as among the Tartars. When the disease bursts in the midst of a family, all the ties of blood and friendship are broken; often the Tartar, quitting then mother, wife, and children, mounts on horseback and flees his country. When the plague descends on a tent in winter, those it attacks are almost infallibly lost, abandoned as they are under a light tent to a cold of more than 25 degrees beneath zero. Sometimes it suffices only fifteen days to destroy a whole family. The only remedy they use is hot milk, diluted with water; the sole preservative is brandy. The Tartars almost never bury their dead; they drag them to some distance from the camp, and leave them on the sand. It is not rare to see a hungry dog carry off a leg, a foot, or an arm, to the tents, and devour it under the sight of the relatives. There are no doctors nor hospitals. There is merely to be mentioned the village of Jardik, on the portal route, with its miserable hospital of fifteen beds. There is, indeed, a medical man attached to the administration of the Kalmucks, far from the centre of the Steppes, at Astrakan; but this doctor's time is always occupied by violent deaths; he has not a moment left for ordinary diseases.

#### Lithotomy and Lithotrity.

DR. MALLEZ (Acad. de Méd., 1st Dec.) read recently a paper on operations by lithotomy and lithotrity, in which are contained the following conclusions: In casting a glance over the surgery of the urinary passages for the last ten years, we are struck with the greater comparative number of operations of lithotomy comparatively to those from 1840 to '50. Lithotrity by the natural passages has ceased to be the rule; lithotomy the exception. The two methods no longer are antagonistic, but complement each other. Persons no longer wait, to practise lithotomy, to be forced into it after useless and fruitless attempts at lithotrity, but recourse is at once had to it; and thus indications appear to be more numerous, and especially more precious, than they were twenty-five years ago. It is in obedience to this general tendency, as well as to the conviction drawn from his own experience, that Dr. Mallez has found occasion to make in two years twenty-four lithotomy operations—an enormous proportion even in an extensive practice, which brings also necessarily with it a more considerable number of lithotrities. Two cases were operated on by thermic galvano-cautery, and one died; two by perineal lithotrity, both of whom died; two by a mixed pre-rectal incision, combined with dilatation of the neck of the bladder; and eighteen by pre-rectal incision, without any other modification than that of the employment of a double cystotome of Amussat. All of these did well.

#### Vaginitis.

PROFESSOR T. D. FINCH (*Chicago Med. Ex.*, No. 22) says there are several varieties of vaginitis recognised—simple, specific, and granular. It may be simple or specific as regards its origin. The simple begins usually with swelling of the vulva and heat, burning, itching, and pains at vulvar extremity of the vagina, often around the urethra, with painful micturition. The inflammation may extend to all mucous canals along the urethra, lighting up a urethritis, perhaps to the bladder, giving a cystitis; along the vagina to cervix, giving endo-cervicitis, or to the cavity of the uterus, giving rise to endo-metritis; or even along the Fallopian tubes to the peritoneal cavity, kindling a fatal peritonitis.

The specific variety, or gonorrhœal vaginitis, differs very slightly from the simple. Very often you cannot tell the difference. Some authorities distinguish them by reason of the greater acuity of the symptoms manifested in the latter variety, the increased urethral inflammation, greater redness and pain in the parts, the mucous surface bleeding freely, and being more sensitive on examination; but be exceedingly careful in giving a positive diagnosis, for the two varieties resemble each other so closely that you will often be unable to detect the slightest difference, and by giving a hasty opinion you may do irreparable injury to an innocent party, and inflict a sting you can never extract.

A man may contract a urethritis from the acrid vaginal discharge occurring during menstruation, or from an endocervical discharge.

There is another variety of vaginitis, the follicular, generally the result of pregnancy, in which the mucous membrane is studded with little red points, that are the hyperæmic and hypertrophied papillæ.

Chronic vaginitis is simply a continuation of the acute, in which the severity of the symptoms is modified. The ordinary duration of an acute vaginitis is about two weeks; that of the chronic form is indefinite—may run on for a number of weeks, months, and occasionally lasts for a number of years. In a patient now under treatment for some two years but little benefit has accrued.

As regards treatment, the cause should be looked to first of all. If due to endo-metritis or vulvitis, these must first be cured. In the acute form, warm sitz baths, mucilaginous vaginal injections, and saline laxatives are useful, and anodynes if there be pain. He recommends an injection of four drachms of chlorate of potash, and ten grains of permanganate of potash, in sixteen ounces of water, of which a teacupful is to be injected morning and evening. Tampons of cotton-wool dipped in tannate of glycerine are useful, introduced every three days, taking care not to stain the linen with the tannin.

### Poisoned by Smoking.

In the *Journal des Connaissances Médicales* we read the following: M. Prof. Chevallier reports in his journal the case of a young man who made a wager that he could smoke twelve cigars, and forthwith went to work to execute his boast. At the eighth cigar he began to experience malaise, at the ninth he had chills and flushes, which phenomena were still more marked at the tenth. He refused to stop smoking, but went to his own house, attended with two of his friends. On arrival he had pains in the bowels and vomiting. A physician was called in, but he was unable to arrest the progress of the disease, and the patient died in the night. It is worthy of note that the subject of this observation was affected with cardiac hypertrophy.

### Animals as Motor Powers.

M. MAREY has laid before the French Association for the Advancement of Science some interesting observations on the employment of animals as motor powers, which we find noted in the *Philadelphia Reporter*. He proves, by means of a very elaborate instrument, that the movement of animated beings as motor powers takes place by jerks, whence results shocks, and consequently a waste of labour. As an illustration of this theory M. Marey cites the effort necessary to draw a burden behind one. If the necessary force be transmitted by means of a rigid or almost unextensible strap, for instance, of leather, the movement is jerky and more difficult than if it were transmitted by an elastic strap. It would, therefore, be better to attach horses to the shafts with india-rubber traces. He also gives as an illustration the manner in which boats are always dragged along the towing-paths by long ropes. It would be impossible, or at least very distressing, to employ short ones. The length of the rope, which alternately tightens or slackens by slow oscillations, has in this case the same effect as india-rubber.

### Primitive Surgery.

ACCORDING to a paper read by Dr. Prunières before the recent Prehistoric Congress at Stockholm, and quoted in the *Philadelphia Medical Times*, trephining was frequently practised during the prehistoric Stone Age. It is stated that the operating surgeons of that date, working with flint im-

plements, scraped the bone, layer by layer, until the dura mater was exposed. Skulls both of children and adults, with the orifices in some instances partially cicatrised, have been found in abundance. The crania have been submitted to M. Broca, and we suppose there is no room for doubt as to the fact that the trephining was in many instances performed during life, although skulls were also discovered from which the circular pieces had apparently been removed after death. It has likewise been observed that the fragments of bone have been replaced in the skull before interment, apparently with the intent that the person should appear in the next world in his entirety.

M. Prunières is of the opinion that the operation was practised for medical purposes, to give exit to a real or imaginary disease, and also that insane persons and epileptics, the friends of the gods of the old beliefs, were especially the subjects of it, and that the pieces of removed bone were used as charms and amulets.

### Cæsarian Section and the Elastic Suture.

A NEW case of Cæsarian section with the elastic suture in the walls of the uterus is reported in the *Gaz. Méd. de Paris*. The case terminated fatally, but union had already taken place by first intention, as in all the other cases. On autopsy, no trace of the line of union could be discovered. The uterus in this, as in the other more successful cases so far as life was concerned, was perfectly free from adhesions.

### The Taste of Human Flesh.

IN the Section of Anthropology during the Congress recently held at Lille, a long discussion was held on the subject of anthropophagy, which is quoted in *La France Médicale*. M. Broca made some remarks upon the different nature of the flesh of different races. He said that cannibals do not like the flesh of white people, which they find bitter and salty, and, moreover, which will not keep, notwithstanding its saltiness, for any length of time. The flesh of negroes, on the contrary, preserves itself a long time without decomposition, and cannibals love its taste.

### Radical Cure of Hydrocele by Electro-puncture.

DR. ERHARDT (*Memorabilien*, No. 8, 1874) has used electro-puncture four times successfully in cases of hydrocele. He made use of the interrupted current furnished by Gaiffe's apparatus. In the first case, where the fluid had only existed a short time, resorption took place in a few days; in other cases it required three weeks. In a man, fifty-two, who for eight years had suffered from hydrocele, puncture was frequently required, for the fluid reappeared every three weeks. Electro-puncture was then employed. Two thick very pointed needles were used in communication with the poles of Gaiffe's apparatus. These were thrust into the tumour at a distance of six centimetres, and three centimetres deep, so that they were in the fluid. The pain was quite bearable, and the current was changed in five minutes, and in another five minutes' time the needles were drawn out, when the needle from the negative pole appeared black and oxidised. In three weeks absorption had taken place permanently.

### Increase of Urea from Coffee and Tea.

DR. ROUX (*Chem. Central. Bl.*) asserts that the solid constituents of the urine are increased, and not lessened, by the use of tea and coffee. After regulated diet, when the solid constituents were found to amount to 33 grammes daily, he found that the solids did not depend on the quantity of water drank. In 944 c.c. of urine there was almost as much urea as in 2155 c.c. From 14th to 18th May his urine contained daily 36.18 grammes of urea. The 18th May, when coffee was taken, 41 grammes of urea were given off; and the same occurred when tea was taken.

### The Local Use of Emplastrum Hydrargyri and Unguent. Hydrargyri in Syphilis.

PROFESSOR DOUTRELEPOINT (*Pr. Arz.*, 1874) has treated the majority of his cases of syphilis locally with emplastrum hydrargyri with success. He states that the base of the indurated sore clears up rapidly under this treatment, and the scarring at its edges is hastened. Broad condylomata leave off giving off moisture, and heal up. Also, in the various syphilitic skin affections, when not too extensive, strips of the plaster laid over the surface cause a quicker disappearance. In a case of syphilitic lichen, the right forearm, which was more affected, was covered with emp. hydrarg., and the other not so, whilst the patient took the yellow iodide of mercury. In eight days the knots on the locally treated arm had disappeared, and were seen only as maculæ, whilst on the left arm there was scarcely any difference since the cure commenced. In tertiary forms of syphilis, even, is this treatment useful. Thus, it was followed by quick cure in a long-continued case of syphilitic lupus. Periosteal gummata heal rapidly, whether ulcerated or not. In several cases of ulcers of the ankle, which arose from destruction of subcutaneous gummata, binding with plaster or mercurial ointment sufficed to heal obstinate ulcerations quickly. Salivation was several times caused by absorption of the mercury.

### Dr. Charcot on Bright's Disease.

In a lecture on Bright's disease (*Progrès Méd.*, No. 47), Dr. Charcot speaks of chronic uræmia, which is especially noticed in cases of interstitial nephritis. Habitual dyspepsia is commonly witnessed, with vomiting at all times, the vomit containing sometimes uræa and carbonate of ammonia. Itching is frequently complained of. *Uræmic amaurosis* should be reserved for these cases of disturbance of vision in which no alteration can be noticed by the ophthalmoscope. This is rare compared to the cases where retinitis is observed. They are diagnosed by the rapidity of their coming on and rapid going off, and frequent returns.

Sometimes peculiar headache exists, accompanied by somnolence and persistence.

Subsultus tendinum is often met with, and sometimes true trembling of the limbs, and such symptoms are sometimes the first signs of chronic Bright's disease.

In some cases acute symptoms supervene at once, and apoplectic accidents may ensue, or epileptiform attacks. The skin has been seen in chronic interstitial nephritis to

be covered with a white pellicle, which has been found to consist of urea.

When the tension of the blood in the arteries becomes lessened by any disease of the heart, the accumulation of urea in the blood may become so rapid as at once to cause death.

Dr. Garrod has shown that in chronic gout the kidney almost constantly presents the alterations seen in interstitial nephritis, and asserts that the gouty kidney differs from chronic interstitial nephritis only in the presence in the papillary parts of the tubes of crystalline urate of soda. Granular nephritis is very common also among persons poisoned by lead, and gout in such patients is more rapid than in others. Opium and calomel are most dangerous in such persons.

### Artificial Butter.

DR. E. FERRAND (*La France Médicale*, No. 96) speaks of the new industry which in these days of extravagant prices of farm produce is arising in Paris and elsewhere. The best attempts made in France are according to the process of M. Mège, and are named "Margarine Mourières." Artificial butter is manufactured on an enormous scale at present in the United States. In 1871 a first patent was taken out at New York for the artificial manufacture of butter, and in the month of November of the same year Dr. La Perouse took out a more complex patent. His process consisted in treating 1,000 kilogrammes of raw meat with distilled water in which an alkaline bicarbonate was dissolved. Chloride of sodium was added, and the whole was boiled. When the boiling had gone on for some hours, the fatty matter separated from the cellular tissues, came to the surface, was collected, purified, and solidified. This was all; and the inventor need not have qualified this product by the name of butter.

Next came M. Mège-Mourières, who in 1873 took out a patent for the fabrication of butter of oleo-margarine. The base of the process consisted in the mechanical separation of the stearine by utilising the melting point of the oleo-margarine, which is not above 15°.55 c. This author having recognised that cows submitted to absolute starvation nevertheless continued to produce butter by this transformation of their own fat, tried nothing less than to produce artificially the modifications which take place in the mammary glands. Chemically he has succeeded; but the sense of taste hesitates. The first thing to be done is to neutralise the ferments, and for this the fat is plunged, as soon as the animal is killed, into a solution of sea-salt and sulphite of soda. It is then crushed in mills and submitted to artificial digestion at a temperature of 40° c. by means of a composition made with the half of a pig's stomach and hypophosphate of lime. When the fat has become perfectly liquid, and no masses are seen, more sea-salt is added, and it is poured into water at 28°-33, contained in wooden tubes. In these the mass of the stearine is deposited in the form of mammillated little masses in the midst of the liquid; it then suffices to place the latter in a centrifugal machine or hydro-extractor to separate completely the oleo-margarine from the stearine. According to the inventor, the oleo-margarine already forms an excellent butter for the kitchen; but he ameliorates the product in this way: he macerates together cream, bicar-

bonate of soda, and hashed cows' teats, and after having passed this mixture through a fine sieve, he adds it with the colouring matter to the margarine. This becomes then thick, and has the taste of cream; it is allowed to cool, passed into large cylinders to convert it into a homogeneous mass, and the product is then perfect. If the butter is to be long kept, we should replace the cream by water for macerating the teats.

It will thus be seen that there is nothing in the process of M. Mège contrary to hygiene. The only danger is that common fats may be cleverly disguised and sold under the name of butter.

If we may trust a patent of 1869, we may regenerate rancid butter by the following process: To 5 lbs. of melted butter 60 grammes of powdered alum are added, and this liquid is passed through a fine sieve, received in cold water; the butter is then worked with saltpetre, sugar, and the salts of milk, and gives an excellent product. Saffron and curcuma are the chief colouring matters made use of.

### Compression in Hydrarthrosis of Knee-joint.

DR. MAURICE LANGIER (*France Méd.*, No. 97) speaks of the rebellious nature of effusions into the knee-joint. Revulsives, such as blisters, circular compression, and operations, have been used. Blisters, which Velpeau praised so much, are not so useful without pressure in addition, in many cases. Compression alone remains as the best treatment. An india-rubber band is made use of on many occasions, but may prove too painful. M. Guyon has substituted a hollow splint behind filled with cotton-wool, and compression is made around this. The limb being placed in the hollow splint, layers of cotton-wool are applied over the knee, and form a thick layer. The circular bandage is rolled round the hollow splint, and thus pressure only acts on the anterior part of the knee. Pain and uneasiness are thus avoided. Several successful cases have been published by M. Guyon by this method. In one case a hydrarthrosis of eight days' standing was cured in a week; in another one, of fifty days' standing was cured in twenty-three days.

### Compulsory Fixing of Sanitary Salaries in Ireland.

WE are gratified to observe that the Irish Local Government Board, although tardily, and in a niggardly spirit, have exercised their power of fixing sanitary salaries by sealed order when the guardians have named inadequate payments. In the Uringford Union the sealed order fixes the salaries as follows:—Executive sanitary officer, £20; consulting do., £15; sanitary do., four, at £20 each; sub-officers, £10. It is probable that a similar order will immediately reach the Waterford Board, fixing the salaries, as in this case, at the maximum.

The special case in which the intervention of the Local Government Board has been most urgently demanded is that of the Dublin Corporation, who have deliberately and wilfully endeavoured to defeat the operation of the Act, and—by the mouth of their Public Health Committee—persistently resist all effectual sanitary reform. At a time when scarlatina had cost the community 600 lives in Dublin alone, and when any other

conclave would have been stirred to something like humanity and energy, the Public Health Committee has divided its time between throwing difficulties in the way of ardent sanitarians and voting large salaries to its *protégés*, the ex-policemen sanitary officers.

A flagrant money job could, and does, at any time, bring together a mob of eager corporators, while a quorum can be had with great difficulty and much canvassing to transact the most urgent city affairs.

### Misplaced Charity.

WE have more than once expressed our belief that much of the munificent charity dispensed in London was thoughtlessly given to unconsidered and even unworthy objects, and served rather to increase vice and hypocrisy than to alleviate the miseries of the deserving poor. This view is, unhappily, corroborated in a speech made at a recent meeting of the Hampstead Branch of the Charity Organisation Society by Mr. Ribton-Turner. He stated, as an example of the evil of indiscriminate alms-giving, that the anonymous "£1000 donor" had given to more than one sham charitable institution, and had, in one case, sent that sum to a society the sole manager of which was prosecuted for fraud and forgery. In another instance, where two donations were transmitted through a bank to a charitable institution, the bankers sent to the society for information regarding the character of the charity before the second donation was paid over. They were furnished with a report, which showed the institution in question to be a sham; but, having no means of communicating with the anonymous donor, they were unfortunately obliged to pay the contribution.

A FASHIONABLE ball, upon a grand scale, was given at Brighton on Thursday last, in aid of the funds for the Hospital for Sick Children.

A CONCERT was given at the Seymour Hall on Monday last, in aid of the infant nurseries and *crèches* of London. It was very well attended.

WE hope we are not premature in announcing the decline of the scarlatina epidemic in Dublin. The Registrar-General's report of this week records 10 deaths, as against 19 last week, and 29 of the previous period.

THE members of the Whittington Dramatic Society gave a performance on Thursday last, in aid of the National Dental Hospital of London. The theatre was crammed with a highly fashionable audience.

TWO of the foremost surgeons of Milan have recently been fined for not giving information concerning a duel which was attended with serious results. The plea of professional secrecy was brought forward, but the court refused to receive it.

THE second meeting of the Dublin Obstetrical Society was held in the College of Physicians on Saturday last, the 12th inst. 1. Dr. M'Clintock, "Morbid Retention of the Dead Ovum;" 2. Dr. A. V. Macan, "A Case of Intra-

uterine Amputation;" 3. Dr. T. More Madden, "Case of Metro-peritonitis following Vaginal Injection"; 4. Dr. Denham, "A Case of Extra-uterine Fœtation."

We learn that Dr. Lombe Atthill, whose name we mentioned in our last issue as that of a probable candidate for the Professorship of Midwifery in the Royal College of Surgeons in Ireland, will not seek the chair. Dr. Atthill has been recently elected to the Presidency of the Dublin Obstetrical Society, an honour which would of itself give him strong claims upon the College if he wished to seek the Professorship.

THE second meeting of the Surgical Society of Ireland took place on Friday evening last, in the Albert Hall of the Royal College of Surgeons, when the following communications were read: Mr. Corley, on "A Case of Parotid Tumour;" Mr. Thomson, on "A Case of Excision of the Knee for Bony Ankylosis with Deformity;" and Mr. H. G. Croly, on "The Removal of a Hair-pin from the Female Bladder."

A MEETING of the Medical Society of the College of Physicians of Ireland was held on Wednesday, the 9th inst., when the following communications were read: 1. Dr. C. E. Fitzgerald (by permission of the Council), "Further Remarks on the Ophthalmoscopic Diagnosis of Intracranial Tumour," with the exhibition of the specimen on which his former paper was based; 2. Dr. T. More Madden, "Notes on the Probable Employment of Anæsthetics in Ancient Times, especially in Scotland and Ireland;" 3. Dr. Henry Kennedy, V.P., "On a Point in the Respiration of the Healthy Lungs."

Our Philadelphia contemporaries give a terrible account of the state of the insane department of the hospital in that city. The *Philadelphia Reporter* justly denounces it as discreditable to the city, and unworthy of this community. There are at this time 1,105 insane persons crowded in the space allotted for only 600. The attendants cannot keep order among them. They are obliged to pack four or five in a cell at night, only intended for one person to occupy, and to make their condition worse, their arms are chained or strapped close to their bodies, and the restraint system in some of its coarsest expressions is rendered inevitable by the lack of sufficient room and attendants.

THE *American Journal of the Medical Sciences* contains a paper, by Dr. Richardson, of Pennsylvania, on the "Value of High Powers in the Diagnosis of Blood-Stains." He concludes that the results of his experiments prove, that since the red blood-globules of the pig, the ox, the red deer, the cat, the horse, the sheep, and the goat, are all so much smaller than even the ordinary minimum size of the human red disc, we are now able, by the aid of high powers of the microscope, under favourable circumstances, to positively distinguish stains produced by human blood from those caused by the blood of any of the animals just enumerated, and this even after the lapse of five years from the date of their primary production. This question is one eminently deserving the attention of English medical jurists and microscopic observers.

### FREE PHOSPHORUS IN MEDICINE. (a)

THE author of this work very correctly judges that, at the present time, when phosphorus is almost the universal panacea, a work that points out how some of the untoward accidents that have attended the administration of this drug may be avoided will be highly acceptable to the profession.

The use of free phosphorus as a nerve-restoring medicine certainly has more of reason and sense than the use of phosphoric acid and various phosphates and pyrophosphates, with a view to the regenerating action of these substances on exhausted nerve-tissue. The great practical difficulty has been to find a form in which to give phosphorus so that it shall not offend the stomach and shall be in an active unoxidised condition. The pharmacy of phosphorus is discussed by Dr. Thompson thoroughly and carefully. It is, says the author, important to bear in mind that phosphorus, when oxidised, is inert therapeutically, and oxidised to but a slight extent, it appears to acquire poisonous properties. Olive-oil, (b) much used as a solvent for phosphorus, will absorb from 600 to 800 times its volume of oxygen; if, therefore, oil be used that has been exposed to the air, solution of phosphorus made with such oil will contain a varying amount of free phosphorus, with hypophosphorous and phosphoric acids, and will be an uncertain and unsafe medicine. Such solvents as alcohol, ether, glycerine may absorb watery vapour, and thus the phosphorus becomes oxidised into hypophosphorous acid, which, it appears, may act as a powerful poison on the system (p. 16). If, therefore, for convenience in dispensing, a solution of phosphorus in alcohol with glycerine be used, care should be taken to preserve it from exposure to the air.

Solution of phosphorus in a vegetable oil, Dr. Thompson considers to be "a preparation liable to become too actively poisonous to retain a place among remedies intended for internal administration."

We cannot agree with the author as to the danger of phosphorus minutely subdivided. If this subdivision be effected under water, there is small risk of the phosphorus becoming oxidised, and when made up into pills with suet, these may be coated over with gelatine and kept in well-closed bottles. The phosphorus pills made by Savory and Moore, if thus kept, retain their phosphorence many months, and we have never seen any mishap from their administration; obviously it is well the pills should be freshly made.

The capsules of phosphorated oil made by Tisy, of Paris, have also seemed to us both safe and satisfactory.

Cod-liver oil Dr. Thompson finds a good solvent of phosphorus; the solution may lose all phosphoric odour, but yet retain full activity, as the case reported at page 27 proves.

Red, allotropic phosphorus Dr. Thompson dismisses with short notice, considering that whatever activity this body may possess is due to some amount of free phosphorus present in it.

The chapters on the dose and form of administration of phosphorus are written with much care, and after patient observation and experiment. The dangers of giving the medicine in solution in vegetable oil, already alluded to in previous chapters, are very conclusively illustrated by more than one instance of poisoning by phosphorated oil.

Hypophosphorous acid appears often to be the really poisonous agent, and yet this acid, in combination with

(a) "Free Phosphorus in Medicine, with special reference to its Use in Neuralgia," a Contribution to Materia Medica and Therapeutics. By J. Ashburton Thompson, Surgeon at King's Cross to the Great Northern Railway Company, Surgeon-Accoucheur to the Royal Maternity Charity, &c. London: H. K. Lewis, 136 Gower Street. 1874.

(b) In the British Pharmacopœia process for oleum phosphoratum it will be observed that the almond-oil is heated to 300° to expel oxygen.

soda or lime, may be given for any length of time without anything like poisonous effects being induced. Dr. Thompson does not say much as to the hypophosphite salts. The phosphide of zinc he commends as a good substitute for free phosphorus, especially if the dose of the phosphide be followed by some mildly acid drink or medicine to decompose the phosphide and set phosphorus free. The saturated alcoholic tincture of phosphorus seems a safe preparation, and the phosphorus pill of pulverised phosphorus made by Cox and Co., of Brighton, given on a full stomach, is a valuable agent in the treatment of neuralgia.

From one-twentieth to one-twelfth of a grain of phosphorus may be given in a pill with safety, and with every prospect of success, in the cure of neuralgia.

The chapters on the therapeutic uses of phosphorus, and the list of cases illustrating its curative action in neuralgia, are worth careful study. The use of the medicine in skin diseases, already noticed by Drs. Burgess, Broadbent, Thorowgood, and by Mr. Erasmus Wilson, is fully discussed.

As a record of past experience and present knowledge with regard to the therapeutic uses of free phosphorus, we regard Dr. Thompson's work as most valuable. For any one desirous of testing further, by clinical experience, the powers of free phosphorus, the formulæ of administration given, together with the cautions regarding dose and mode of exhibition, will render the work one of the greatest practical utility.

## CURRENT LITERATURE.

### NEW EDITIONS.

WE have on our table new editions of several excellent works, in several of which we notice distinct improvements. First of all, we may mention—

A "Pharmacopœia Companion" to the "Visiting List" has been issued by Messrs. Baillière, Tindall, and Cox. It cannot fail to be useful to many, as it consists of a table of the doses of all the medicines in the British Pharmacopœia, arranged by Dr. Bartley, of the Bristol Eye Hospital. Everyone should insert one of these useful companions in his Visiting List or Diary.

SQUIRE'S "Companion to the Pharmacopœia" (Churchill), which has now reached the tenth edition, and has made itself indispensable to both prescribers and dispensers. Mr. Squire has embodied in his work the Addendum to the British Pharmacopœia, and a number of remedies lately introduced into practice, such as croton chloral, guarana, and coca. He also furnishes a comparison of our official formulæ with those of foreign countries, and he has rewritten for this edition his Therapeutical Index, which is really very well done. His account of the various mineral waters will also be found very useful for reference.

GARROD'S "Materia Medica" has also been brought down to date by the introduction of the necessary additions in their proper places of all our new remedies, including those in the Addendum of the British Pharmacopœia. The new edition, edited by Dr. Buchanan, is worthy of its predecessors, and we believe this work will continue to be the favourite text-book on the subject, as it well deserves to be.

PEREIRA'S "Materia Medica" (Longmans), in its abridged form, has also been revised since the publication of the Addendum; and both students and practitioners who prefer this volume will find in it all they require. Its statements may be always relied upon, and it is a very handsome addition to any medical library.

RINGER'S "Therapeutics" (Lewis), is not exactly a work for students, but its success appears to indicate that a considerable number of readers are satisfied with it. In the new edition the author has inserted some of his recent papers, such as that on "Ipecacuanha Spray." Indeed,

the whole book may be regarded as a record of the author's conclusions interspersed in an abstract of Bucheim's work, on which it is acknowledged to be founded. We have previously mentioned some of the short comings of the book, and may be excused from repeating them. The author will, we fancy, be accused by the homœopaths of poaching on their preserves, as he has been before, but we do not recognise their right to the exclusive use of any remedy.

DR. H. BENNETT'S charming description of "Winter and Spring on the Shores of the Mediterranean (Churchill)" again comes to us fresh and full of life, at a season when fogs and wind and wet combine to make us almost envy the lot of those whose lines are cast in sunny places. Hundreds of our countrymen have already followed the swallows, and hundreds more are rushing southwards in search of health, gasping for the sunshine of which we get so little in these islands. Dr. Bennett continues faithful to Mentone, but he gives fair descriptions of the other health resorts he has visited; and as he takes a look at a new one, whenever he gets a chance, his volume grows in bulk with each succeeding edition. His style, however, continues as agreeable as ever, so that we read the new descriptions with as much pleasure as the old.

CLAY'S "Manual of Obstetric Medicine and Surgery" has reached a third edition. It is a very handy book, and well deserves the success it has attained.

## Correspondence.

### TYPHUS FEVER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It appears from the public papers that the disease called "typhus fever" has been clearing a place called "Over Darwen" of some of its surplus population; it has been set down as a "terrible scourge" wherever it has appeared, and no doubt is and will be until its true nature has been scientifically defined, and treated accordingly. I have in the columns of this journal repeatedly endeavoured to clear up this point by denying its existence as a substantive disease. The term fever is familiar to all but it simply means the skin heated above its normal temperature, and typhus means stupor, or a state of torpor or stupidity. Why this term has been applied to this disease I cannot tell, but its treatment will of course depend upon its fictitious name: as fever it is called, and as fever it will be treated; but where is this disease? The symptoms are pretty clearly defined. There is the rigor, the hot skin, the quick pulse, the headache, the loss of appetite, the foul dry tongue, the dry mouth and throat, the thirst, the high-coloured ammoniacal urine, with sediment, &c., &c., &c., these or most of them being present in a greater or less degree of violence, agreeably to the virulence of the poison, nature, habit, constitution, and sex of the patient. As the disease advances and becomes more alarming, with fetid hot breath, clammy skin, glassy eyes, and sinking pulse, &c., then the word typhus is employed. These are nearly all the symptoms: now, where is the disease?—in what part of the body is it located? I have asked these questions before; I now ask them again. Is it in an artery, vein, nerve, or lymphatic? Is it in the liver, kidneys, lungs, or any glandular organ? Is it in the skin or brain? If in the latter it would be called "brain fever." If it is in none of these, where can it be? To say that it is in the whole system would, I think, overleap the boundaries of prudence, because I have mentioned parts in which it is not. Not knowing where to locate it, and not knowing its exact nature, how can we treat it scientifically? I must now consider the blood as containing a miasmatic poison, absorbed through the lungs from the atmosphere, as being the cause of all these symptoms: when I look in a scientific point of view at that foul dry tongue, that dry arid throat and mouth, that urgent thirst, crying out for drink, drink, drink, I must ask, what state must the mucous coat of the œsophagus and stomach be in? Look at the urine, tongue, gums, &c., and ask what state must that blood be in from which there are such secretions? Here is Nature

herself pointing out the disease. Each particular poisonous miasma has a peculiar tendency—to wit, that which causes a determination of blood to the cuticle, and sometimes affecting the mucous membrane of the mouth and throat, is called scarlet fever; others produce measles, small-pox, &c., and this peculiar disease has a tendency to cause a rush of blood to the mucous coat, mouth, stomach, and bowels, as Nature has pointed out, and hence its name should be gastro-enteritis. Knowing this to be the case in a scientific point of view, we can fancy how it ought to be treated. The call for drink shows that the stomach must be as dry as the tongue, and cold water, containing the nitrate of potash, allays thirst sooner than any other fluid I know of, and in so doing answers the call of Nature admirably; the bowels must be kept free and the secretions carried off. The nervous system must be kept quiet by small doses of morphine or belladonna. Science points out that rest and sleep are just as necessary as fluid to allay thirst. What are febrile symptoms? The fact is, there is only one, and that is heat of skin; all the others depend upon it; and it is caused by increased arterial action. Look over the Pharmacopoeia and point out any medicine which will have a quicker and better effect upon the circulation than the nitrate of potash. James's powder, Dover's powder, fever powders are frequently given; but will any one of them lessen in any way the heart's action? I never lost a patient whose system I could place under the influence of mercury; but where that did not succeed the potash did. You will always find curious exceptions to facts and theories. We took a French slave once, and this disease was on board; one of the crew was very ill, and he managed to escape from his attendant and jumped overboard. When we got him back safely in his hammock the disease had disappeared. Another, from excessive loss of blood, had the same effect. These, I said, are exceptions to any mode of treatment. Nature and science both point out that the poisoned blood in these cases acts upon the mucous coat of the tongue, throat, stomach, and bowels, and we are bound to try and counteract its effects. Some men of talent will, perhaps, combat my views, but if they do, I hope it will be by stubborn facts. In my view, I think I have adduced facts which I think are patent to all, and of scientific form. This poison will force the blood into the muscular and other coats, and in violent cases into the peritoneum. Where there is the slightest epigastric or abdominal pain on pressure, there you will find increased arterial action, and counter-irritation by turpentine and hot flannels, or cantharides, will often be found of invaluable service; but you must guard against mistaking the pain of the one for the pain of the other. Climate does not alter this disease, for the symptoms will be the same in any climate; but there will be a difference in the virulence of the poison, and this will, of course, cause the symptoms to be more violent or urgent. Thirst is caused by the absence of water in the blood, from whatever cause; the vessels having none to secrete, the mucous coat becomes dry or parched, hence thirst. The state of the tongue, mouth, throat, and stomach will depend upon the condition of the blood, and I think Nature or science points it out very distinctly. The removal of a patient to a purer atmosphere, if possible, is always desirable; but where that is impossible, a current of air through a room or ward is highly desirable. When the skin has been burning hot, I have often relieved it, and also the thirst, by having the body sponged over with cold water, and the patient has invariably expressed and experienced great relief and satisfaction. I anxiously hope that my views may tend somewhat to the elucidation of this terrible malady.

I am, Sir, yours faithfully,

ALEXANDER LANE, M.D. R.N.

Douglas, Isle of Man, 20th Nov., 1874.

P.S.—I wish to be understood that particular poisons have a tendency to particular parts of the body—to wit, one poison, causes gout, another the disease called fever, others again, measles, small-pox, scarlatina, erysipelas, &c. &c., and each poison drives the blood to a different part of the body.

—A. LANE.

## Medical News.

University of London.—The following gentlemen passed the recent examination for Honours:—

B.S. EXAMINATION.

First Class.

Gould, Alfred Pearce (*Scholarship and Gold Medal*), University College.

Duncan, Peter Thomas (*Gold Medal*), University College.

Ulster Medical Society.—The opening meeting of this society was held in the rooms of the General Hospital on the 3rd inst. There was a good attendance of members to hear the inaugural address by the new president, Dr. Charles D. Purdon, "On the Past Medical Charities of Belfast as compared with the Present." After the delivery a vote of thanks was proposed by Dr. John Moore, and seconded by Dr. Stewart, and unanimously accorded to Dr. Purdon for his interesting address.

## Cleanings.

Differentiation of Intestinal Invagination.

DR. O. LEICHTENSTEIN, in an article on invagination (*Archiv. f. Prakt. Heilk.*, 4, 1873), refers to the following points for the differentiation of invagination of the small from that of the large intestine: 1. Invagination of the small intestine but rarely occurs during the first year of life, as also rarely during childhood in general. 2. In adults, the course of the attack in invagination of the ileum is more rapid, the phenomena more severe, than in ileo-caecal and colon invaginations. Chronic cases are rare in invaginations of the small intestine, more frequent in those of the ileo-caecum and colon. Severe symptoms of collapse occur more frequently in the beginning of the disease. 3. Muco-sanguinolent discharges are the rule in all invaginations, whatever their seat. Faecal evacuations, entirely normal in character (after preceding diarrhoea) were observed in ileo-caecal invaginations, once in a colon invagination, the patient being an adult. 4. Meteorism is a very variable symptom. It is usually absent in ileo-caecal invaginations. In invaginations of the descending colon it was frequently recognised as affecting the transverse colon; and subsequently spread over the whole abdomen. In invagination of the ileum it was occasionally found to be confined principally to the central abdominal region, with exemption of the lateral portions and epigastrium. 5. Tenesmus is rare in invagination of the ileum, frequent in that of the colon and ileo-caecum. 6. The tumour is usually absent in ileum invagination. Its seat in the centre of the hypogastrium speaks for this variety; when situated in the caecal region, especially when it remains stationary for some time, it indicates ileum or ileo-caecal invagination. The spread of the tumour, when occurring suddenly and corresponding to the course of the colon, speaks more for ileo-caecal, less for colon invagination, and excludes ileum invagination. The seat of the tumour in the left lateral portions of the abdomen would indicate ileo-caecal or colon invagination. The tumour can never be felt in the rectum, and prolapse through the latter never occurs in uncomplicated ileum invagination. Changes in the consistency, occurrence, and disappearance of the tumour were especially observed in the ileo-caecal invagination.—*New York Medical Journal*, Sept., 1874.

Trichinosis Produced by the Meat of a Dog.

In January, 1874, as reported in the *Correspondenz-Blatter des Allgem.*, a woman was admitted to the hospital in Langensalza, suffering from very grave symptoms, all pointing to the existence of trichinosis, and upon subjecting a small excised fragment of the deltoid muscle to the microscope, numerous encapsuled parasites were readily detected. This being the only instance of the disease known to have occurred in the vicinity at that time, the attempt was made to elucidate the source of the infection, which resulted in extracting from the patient the following extraordinary statement:—

For many weeks previous to her illness her extreme destitu-

tion had prevented her from purchasing any meat of any sort, nor had she been able to buy any fat, nor any other portion of a hog. Her meals were all prepared at home, her food consisting of dogs, cats, and also, during the season, marmots and foxes. The only meat which had been brought into the house for many weeks consisted of a pair of cats, the greater part of which was still left, having been smoked, and a dog which had been sent her for culinary purposes by a neighbour. This animal appeared very fat, and upon killing him she observed that a quantity of yellow fluid was contained in the thoracic and abdominal cavities, and that the meat, which was of a very pale colour, could be pressed together like a sponge.

President of the Royal College of Surgeons in Ireland ..... 541

## ORIGINAL COMMUNICATIONS.

M.D. Edin. .... 543

become infected by consuming the flesh of the diseased dog. She was restored to health at the expiration of four months.

## Trophic Affections following Cerebral Lesions.

DR. A. MURON, in the *Gaz. Méd. de Paris*, September 26, 1874, calls attention to certain trophic affections hitherto undescribed, which may appear in the course of the evolution of cerebral lesions, particularly cerebral hæmorrhage. These affections are of two kinds—external and internal.

Under the term "external affections" Dr. M. includes lesions of the parotid characterised by suppurative inflammation, of the region of the buttocks characterised by a simple congestion of the integuments and subcutaneous cellular tissues, and of the knee characterised by a hypersecretion of synovial fluid.

Dr. M. cites, as belonging to this class, a case in which cerebral hæmorrhage into the right corpus striatum was followed six days later by severe inflammation of the parotid, going on to suppuration, which was only cut short by the death of the patient.

At the same time the region of the buttocks on the paralysed side was observed to be red and vascular, but without pustules or scars, while the corresponding knee was slightly tumefied, and there was probably a certain degree of hydrarthrosis.

Under the term "internal trophic affections" Dr. Muron includes congestion of the kidney of the affected size, and he gives several instances of this class of cases. The first was that of a patient who had suffered a bullet-wound of the brain, involving the middle of the left hemisphere and the third frontal convolution.

Post-mortem examination showed the right kidney considerably enlarged and deeply congested, but without any degeneration of the uriniferous tubules.

A second case is that of a patient 50 years of age, who had suffered two months from left hemiplegia.

Post-mortem examination showed the hæmorrhagic clot to have been formed at a point external and posterior to the corpus striatum. The left kidney was found to be at least one-fifth larger than the right, and much firmer in consistency, while very decided congestion was evidently present. That this congestion was recent was shown by the absence of granular fatty degeneration of the uriniferous tubules, while the cellules of the capillaries were more or less completely infiltrated with numerous pigment-granules. Other cases of a similar nature are referred to, and the paper is concluded by a description of a case of clinical interest, in which cerebral hæmorrhage followed by left hemiplegia without loss of intelligence was accompanied by temporary albuminuria. This latter disappeared with the gradual amelioration of the paralysis.

## NOTICES TO CORRESPONDENTS.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

MR. BEAN, Ashburton, is thanked for his complimentary note. The contents of the latter portion will receive attention.

DR. LEBEAU, Paris.—1. If it will save you trouble, you can make your subscription payable to our agents in Paris—Messrs. Baillière,

Rue des Ecoles de Médecine. 2. The first of Mr. Allingham's papers, "On Fistula," appeared in our issue of December 2nd. Dr. ADAMSON'S communication was received as we were going to press. It will have early attention. Dr. C. C.—A day too late.

## MEDICAL ETHICS.

DR. CAMPBELL BLACK writes to say:—In these days of chicane and Protean medical quackeries it is not surprising that the excellent and manly letter signed "Themus," which appeared in your impression of the 2nd inst., should have been allowed to pass without comment in the succeeding impression. For my own part I have received "at sundry times, and in divers manner" the friendly hint that on the subject of medical charities in particular, and medical ethics in general, I am believed to be the victim of a monomania, and I was naturally timid of confirming the impression so soon after the publication of my pamphlet "On Medical 'Charities.'" Perhaps I might do something to un-derceive my anxious friends if I indicate that there may be method in my madness, and with your kind permission I desire to refer as methodically as possible to the subject so ably treated by "Themus," and show him and others that this, the "second city" of the empire, distinguished as it is by piety and drunkenness, is no less distinguished by professional procedures of a most questionable nature. We, too, have our College of Physicians in the shape of a *qualifying body* termed the Faculty of Physicians and Surgeons.

Without stopping to examine or criticise the causes likely to give rise to a manifesto to regulate personal conduct, I simply remark that this body, the *Faculty of Physicians and Surgeons*, in a moment of pious exaltation, conceived, and was safely delivered of a code of ethics, including the following: "It is derogatory to the dignity of the profession to resort to public advertising or private cards, or handbills, inviting the attention of individuals affected with particular diseases, publicly offering advice and medicine to the poor gratis, or promising radical cures, or to publish cases and operations in non-medical prints. . . . These are the ordinary practices of empiricism, and are highly reprehensible in a regular practitioner. . . . There is no profession by the members of which eleemosynary services are more liberally dispensed than the medical, but justice requires that some limits should be placed to the performance of such offices. Poverty and professional brotherhood should always be recognised as presenting valid claims for professional services; but neither institutions endowed by the public or by rich individuals, societies for mutual benefit, for the insurance of lives, or for analogous purposes, nor any profession or occupation, can be admitted to possess such privilege."

Such being the terms in which *The Faculty* dictates not only to its own members and Fellows, but the smaller lights beyond its pale, it is instructive to inquire how this code of ethics is regarded by its framers. We can easily get at a solution of this question. There are nine special institutions in Glasgow, and everyone knows their object and mode of creation. . . . In fact, there is but one special institution in Glasgow which was not founded by one or more members of the body which framed the code of ethics above quoted. Further, the originating of special institutions being regarded now, in Glasgow, as the only means of making a practice, it is deemed essential by intending speculators in this department, in the first place, to join the Faculty, in order to be able to break its code of ethics in an honourable manner!! . . . The Faculty of Physicians has not legislated as to the advertising of books, as, I presume, it was never supposed that any of its Fellows were likely to err in this manner. I have seen a Fellow pretty high up put into a fine state of mind on being challenged as to the meaning of *ad eundem*! "Themus" may deplore the want of Latin and Greek; we would be content with decent English. For my part, I see no immorality whatever in the advertising of an honestly-written book, and of this each individual must judge for himself. The heinousness of all advertising I take to be misrepresentation, and, judged by this rule, special institutions as "charities" supported by the public are demoralising shams, hurtful to the profession, subversive of honesty, a fruitful source of vice, and unworthy of adoption by anyone affecting a spark of manliness. If, on the other hand, this be a means of making a practice, let members of the medical profession give this to be understood—eliminate the misrepresentation, and let us all be put on an equal footing, each man having his own clinique, as obtains on the Continent.

The Glasgow Faculty is very sensitive on the score of medical shop-keeping, yet it has two "Inspectors of Drugs!" A man who keeps open shop is not eligible for election to the Fellowship of the Faculty, no matter how much the conduct of the Fellows may tend to make this disagreeable though often necessary line of practice indispensable. A man finds himself in the position of having no fortune, the special institutions tempt the public to them, Fellows of Faculty start and maintain these institutions, take away the chances of making practice on the part of the beginner; to live he must open a shop, but then he becomes, *ipso facto*, disqualified for the Fellowship of the Faculty. More, there are two large drug halls (halls) in Glasgow. They were established by Fellows of Faculty, and in the foremost ranks of this body more than one, if I mistake not, having been President. The hair-wash of one, with his name duly paraded on the label (a late Professor at the University, I regret to say), is to be found in the drug-shops of Glasgow; the antibilious pills of another; and the corn-plaster of a third. What has "Themus" to say! For my part, I think that the man who requires a code of ethics to regulate his conduct in life is a despicable fellow; the medical profession has as many quacks within as without its ranks; it will never improve but commensurately with a better education on the part of the public.

## VACANCIES.

Royal College of Surgeons of Ireland. Professorship of Midwifery. (See Advt.)

West Riding Asylum, Wakefield. Clinical Assistant, to take notes of cases and to assist the medical officers generally. Board and apartments, but no salary. (See Advt.)

North-Eastern Hospital for Children, Hackney. House Surgeon Salary, £100, with furnished apartments, &c. (See Advt.)

Letterkenny Dispensary. Medical Officer. Applicants must address the Hon. Sec. (See Advt.)

Parish of St. James's, Westminster. Medical Officer of Health and Analyst. Salary, £300. Applications to the Vestry Clerk.

Evelina Hospital for Sick Children, Southwark. Physician. Honorary. Also a Medical Registrar. Salary, £20 per annum.  
Western Dispensary, Westminster. Resident Medical Officer. Salary, £105, with furnished rooms. Address the Secretary, 1 Artillery Row, London, S.W.

Lock Hospital (Male), London. House Surgeon, with board and furnished apartments. Full particulars of the Secretary.  
Hant's County Lunatic Asylum. Junior Assistant Medical Officer. Salary, £100, with board and lodgings. Address, Dr. Manley, at the Asylum.

Newcastle-on-Tyne Lunatic Asylum. Assistant Medical Officer. Salary, £100 per annum, with board and apartments. Forms of application to be obtained from the Superintendent.

Sheffield Public Hospital. House Surgeon. Salary, £100, with board and residence. Address, Dr. Hall, at the Hospital.

Chorlton Union. Resident and Assistant Resident Medical Officer. Salary, of the first, £250, and of Assistant, £125 per annum. Address the Clerk to the Guardians, Manchester.

#### APPOINTMENTS.

BRAMISH, W., M.D., Senior Physician to the Cork Fever Hospital.  
BELLIN, E., L.R.C.P.I., L.R.C.S.I., Surgeon to the Ditton-brook Iron Works, Ditton, near Warrington.

CLARKE, J., M.D., Superintendent Medical Officer of Health and Sanitary Officer for the Mountmellick Rural Sanitary District.

DEELEY, W., M.D., Resident Medical Officer to the Malton Dispensary.

DICKSON, J., M.B., L.R.C.S.Ed., Medical Officer for the Frodingham District of the Driffield Union, Yorkshire.

ETHERIDGE, G. E. F., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for Froome-Bishop District of the Bromyard Union, Herefordshire.

GARDNER, F., M.R.C.S.E., Medical Officer and Public Vaccinator for No. 7 District of the Barnstaple Union.

LUTROF, H., L.R.C.P.L., M.R.C.S.E., Medical Officer for the Alveston District of the Stratford-on-Avon Union; also a Medical Officer to Stratford-on-Avon Medical Provident Institution.

MCCLURE, T., L.R.C.P.Ed., F.R.C.S.I., Medical Officer for No. 2 District of the Axbridge Union.

MACKENZIE, G. H., M.B., C.M., Assistant Surgeon to the Gateshead Dispensary.

MORRIS, H., M.R.C.S., Medical Officer to the Cottage Hospital, Sheffield.

MURCHISON, F., M.A., M.B., C.M., Assistant Medical Officer to the Crichton Royal Institution, Dumfries.

PALEY, W. E., M.R.C.S.E., House Surgeon to the Evelina Hospital for Sick Children, Southwark.

POWELL, W., M.R.C.S.E., Medical Officer for Bromyard District, and Medical Officer for the Workhouse of the Bromyard Union, Herefordshire.

PRICE, F. T., M.R.C.S.E., Resident Medical Officer to the St. George Dispensary, Mount Street, Grosvenor Square.

PRYNN, E. M., M.R.C.S.E., Medical Officer for No. 8. or Southern District of the Plymouth Incorporation of the Poor.

PURDON, E., L.R.C.P.Ed., L.F.P. & S. Glas., Assistant Medical Officer to the North Riding Lunatic Asylum, Clifton, Yorkshire.

SMITH, A. P., L.R.C.P.Ed., L.F.P. & S. Glas., Medical Officer for the Shawbury District of the Wem Union, Salop.

SUTTON, F., M.R.C.S.E., Medical Officer for the Willingham District of the Gainsborough Union.

THORPE, G. E. K., M.R.C.S., a Surgeon to the Public Hospital, Sheffield.

TRENNY, G. W., M.R.C.S.E., Medical Officer of Health for the Penryn Urban Sanitary District.

WEBSTER, H. W., L.R.C.P.Ed., M.R.C.S.E., Resident Medical Officer to the Woolwich Union Workhouse and Infirmary.

WHITE, J. B., M.D., C.M., Resident Medical Officer at the Hackney Union Infirmary, Hoxton.

#### Birth.

DAVSON.—On the 10th inst., at Dartmouth, the wife of F. Adams

DAVSON, M.D., of a son.

KELLY.—On the 4th inst., at 12 Plough Road, Rotherhithe, the wife of Bernard Kelly, M.D., of a son.

#### Marriages.

BROWN—HUGHES.—On the 3rd inst., at King's Kerswell, Devonshire.

Anthony Lennon Brown, L.R.C.P.I., Army Medical Staff, to Jane Maria, daughter of the late John Hughes, Esq.

LOMNER—RYNOLD.—On the 10th inst., at St. Mary's Church, Rotherhithe, S.E., R. H. Lomner, son of Deputy Surgeon-General Lomner, M.D., to Jane, daughter of J. Reynolds, of Rotherhithe.

#### Deaths.

DATE.—On the 29th Nov., William Date, M.R.C.S.E., of Cr. wkerne, aged 85.

FRESHFIELD.—On the 4th Dec., at the Crescent, London Road, Ipswich, Philip Wm. Freshfield, Surgeon, of Harwich, in his 60th year.

HUGHES.—On the 29th Nov., lost in the S.S. *La Plata*, off Ushant, John Rigby Hughes, M.B., of Guy's Hospital, and Ruicorn, Cheshire, aged 30.

KEL-ALL.—On the 3rd Dec., Henry Kelsall, M.D., of Redhill, Reigate, late Surgeon R.N., aged 72.

MATTHEW.—On the 3rd Dec., Alex. Crombie Matthew, M.R.C.S.E., of Albyn Place, Aberdeen.

PRICE.—On the 3rd Dec., John Cooke Price, M. & L.S.A.L., of Dovercourt, formerly of Stamford Hill, aged 75.

ROBINSON.—On the 27th Nov., at Robert Street Regent's Park, Andrew Ker Robinson, Surgeon, aged 32.

## Advertisements.

**PARTNERSHIP, £150.** For this small amount a SURGEON can become a PARTNER in a well-established practice, and have a certain amount of Income guaranteed and secured to him. Fine double-fronted shop, in a good thoroughfare, centrally situated. Profits, on the ready money alone taken over the counter, upwards of £8 per week. A Partner who could do the outdoor work would double the receipts, as this branch has never been attended to. Trial allowed. Messrs. DEBENHAM and CO., Auctioneers, 2 King's Road, Bedford Row, London, W.C.

**Ulster Medical Society.**—The opening meeting of this society was held in the rooms of the General Hospital on the 3rd inst. There was a good attendance of members to hear the inaugural address by the new president, Dr. Charles D. Purdon, "On the Past Medical Charities of Belfast as compared with the Present." After the delivery a vote of thanks was proposed by Dr. John Moore, and seconded by Dr. Stewart, and unanimously accorded to Dr. Purdon for his interesting

#### ROYAL COLLEGE OF SURGEONS IN IRELAND.

The President and Council hereby give notice that on Thursday, the 14th day of January, 1875, at the hour of 2 o'clock, they will proceed, according to the provisions of the Supplemental Charter, to elect a Professor of Midwifery in the room of Dr. Sawyer, resigned. Candidates are requested to lodge their applications, at the College on or before the 7th of January, 1875.

By order of the Council,

December 4th, 1874.

J. STANNUS HUGHES,

Secretary to the Council.

**NORTH-EASTERN HOSPITAL for CHILDREN, HACKNEY ROAD, E.—HOUSE-SURGEON** required for the above Institution. Salary, £100, with attendance, rooms, coals, and light. Double qualification preferred. Apply by letter, stating age, with Testimonials, &c., to the Secretary, Mr. J. W. Sibley.

#### INDIAN MEDICAL SERVICE.

**NOTICE is HEREBY GIVEN, that an EXAMINATION of CANDIDATES for Twenty Appointments as Surgeon in Her Majesty's Indian Medical Service will be held in London in February, 1-75.**

Copies of the Regulations for the Examination, together with information regarding Pay and Retiring Allowances of Indian Medical Officers, may be obtained on application at the Military Department, India Office, London, S.W.

A further notice will be issued when the exact date of examination has been fixed.

T. T. PEARS, Major-General, Military Secretary.

India Office, 1st December, 1874

**UNIVERSITY OF LONDON.**—The following are the Dates at which the several EXAMINATIONS in the UNIVERSITY of LONDON for the year 1875 will commence:—

Matriculation.—Monday, January 11, and Monday, June 23.

Bachelor of Arts.—First B.A., Monday, July 19.

Second B.A., Monday, October 25.

Master of Arts.—Branch I., Monday, June 7.

Branch II., Monday, June 14.

Branch III., Monday, June 21.

Doctor of Literature.—First D.Lit., Monday, June 7.

Second D.Lit., Tuesday, October 12.

Scriptural Examinations.—Tuesday, November 23.

Bachelor of Science.—First B.Sc., Monday, July 19.

Second B.Sc., Monday, October 25.

Doctor of Science.—Within the first twenty-one days of June.

Bachelor of Laws.—First LL.B., } Wednesday, January 6.

Second LL.B., }

Doctor of Laws.—Thursday, January 14.

Bachelor of Medicine.—Preliminary Scientific, Monday, July 19.

First M.B., Monday, July 26.

Second M.B., Monday, November 1.

Bachelor of Surgery.—Tuesday, November 23.

Master in Surgery.—Monday, November 22.

Doctor of Medicine.—Monday, November 22.

Examination for Women.—Monday, May 3.

The Regulations relating to the above Examinations and Degrees may be obtained on application to "The Registrar of the University of London, Burlington Gardens, London, W."

December 10, 1874.

WILLIAM B. CARPENTER, M.D.,  
Registrar.

**LETTERKENNY DISPENSARY.**—The Committee of the above Dispensary will meet on Tuesday, the 20th inst., for the purpose of electing a properly qualified person to succeed Dr. Gen. E. Carré, who has accepted the appointment of Resident Medical Superintendent of the Castlebar Lunatic Asylum. The following appointments were held by Dr. Carré:—viz.: Physician to the Donegal District Asylum; Medical Officer Letterkenny Fever Hospital; Surgeon to the Donegal Artillery, &c. Candidates for the Dispensary may forward their Applications and Testimonials to

Lisnennan, Letterkenny  
Dec. 12th 1874.

## Introductory Address

DELIVERED AT THE  
OPENING MEETING OF THE  
SURGICAL SOCIETY OF IRELAND.

By JOLIFFE TUFNELL, F.R.C.S.,  
President of the Royal College of Surgeons in Ireland.

As President of the Royal College of Surgeons in Ireland, I have the honour of being (*ex officio*) Chairman of this Society, and in that capacity it becomes my privilege to address you at the commencement of the present session. Before doing so, however, I would beg to express the pride and satisfaction which I feel at being raised to this honourable position; and let the first words that I give utterance to from this chair, be those of thanks to my brother Fellows who by their kind votes have conferred this honour upon me—for I do indeed feel it to be such. The promotion to the chair of the Royal College of Surgeons in Ireland must be gratifying to any man, for, if not possible to be of those great ones who have held the Presidentship, and passed away, and gone, still, it is an honour for any individual to have his name placed upon the same roll, and even to this extent to be associated with them. For this privilege I feel very grateful, and would again so express myself to every Fellow of the College. Now, in reference to the constitution of this Society (the 44th session of which we are met here to inaugurate this evening), the purposes for which it was founded, the construction of its governing body, the duties of the President and those honorary officers the Secretaries and the Publication Committee, by whose labours conjointly the hard work of the Society is performed, these have already upon previous occasions been so ably and fully brought forward that there is very little left for me to say. My observations, therefore, will be brief, and addressed solely to those junior members who may perhaps for the first time be

sitting here to-night. To them I would say that this Society was founded in 1831, for the purposes of forwarding the interests and progress of medical science in general, and although termed "surgical," in consequence of being in connection with the College of Surgeons, its appellation would more fitly be that of the Medico-Chirurgical Society of Ireland, since it embraces every single subject pertaining or allied to the practice of our profession. By its rules human and comparative anatomy, pathology and physiology, materia medica and pharmacy, botany and zoology, chemistry, meteorology and natural philosophy, geology and mineralogy, medical jurisprudence, hygiene and State medicine and statistics, in addition to midwifery, medicine and surgery, are one and all eligible to be brought before it—a broad basis indeed, admitting everything, and excluding nothing that can possibly tend to the advancement of professional knowledge. So established, let us for one moment refer back to those who were the originators of this Society. In doing so we shall find them to have been Benjamin Alcock, Robert Adams, Thomas Beatty, Charles Benson, Richard Carmichael, Fleetwood Churchill, Dominick Corrigan, Philip Crampton, James Cusack, Andrew Ellis, Robert Graves, William Hargrave, Robert Harrison, John Hart, John Houston, Arthur Jacob, John Kirby, Ephraim Macdowell, Rawdon Macnamara, Henry Maunsell, William Montgomery, James O'Beirne, Richard O'Reilly, William Henry Porter, Alexander Reade, and though last, not least, Robert Williams. An institution thus founded and fostered could not but succeed. To you who have known these men personally, and to you who know them by reputation and name, I put the question—if greater intellect, if a more dignified array, ever graced the muster-roll of any embryo society? The working of this Society has been entrusted from its foundation to a Council consisting of twenty-one Fellows of the College. Those who had been originally nominated made arrangements for filling up such vacancies as should from time to time occur by selecting from among the Fellows of the College those who had practically manifested their interest in the welfare of the Society by their valuable contributions, the names of all such having been previously subjected to the Council of

the College for approval. This power of election to Council has recently been altered, and by the last bye-laws, all members of this Society, being Fellows of the College of Physicians or of Surgeons in Ireland, have the right of voting for Council, such voting being by ballot early in November of each year. To this Council of twenty-one members, so selected, all power is entrusted for the regulation and management of the Society, subject to the approval of the Council of the College. This point must not be forgotten—viz., that the Council of this Society is under the control of the Council of the College. Associated with the Council of the Society are the President and the Vice-President of the College (*ex officio*). It is the duty and privilege of one or other of these to take the chair and preside over every meeting, and in their absence the senior member of Council of the Society present is entitled to preside. Now, the duty devolving upon the Chairman is one of very great responsibility in connection with the subject of debate. The power of discussion allowed by the rules of this Society is, I consider, not only most desirable, but really essential to its success, for the remarks elicited in debates are oftentimes the exponents of long practice and great experience. The power confided to the chair in every society is great, but in this one paramount; for to the President is deputed authority to stop at any moment that he thinks fit the discussion then proceeding, and to press on to other business—a good power so long as it is judiciously used—an unjust and tyrannous autocracy if abused. I can only say that during the coming session, although I may act with firmness, I trust that it will be with fairness to every speaker that addresses the chair, for we must never forget that it is to the chair, and the case under discussion, that one should speak, and not personally against the advocate of an opposite view from that of the speaker. I can only once more say that I will (as Chairman) endeavour to be as free from partiality, favour, or affection, as mortal can. Associated with the President and Council are the Honorary Secretaries and the Publication Committee. For the Secretaries I would say a few words, in the hope of gaining the cordial co-operation of the members of the Society, because upon the energy and exertions of the Secretaries does the success of each meeting entirely depend. Do not for one moment suppose that the labour of the Secretaries consists merely in reading out the proceedings of the former evening, or at the meeting of Council taking notes of the doings of the day. No, the Secretary has often to exert himself to a degree that no one can know, unless he has (as I have done) acted as Secretary for some time. Gentlemen will often put down their names as contributors of papers for a certain evening, and that to the exclusion of others, and then at the eleventh hour begin each one to excuse himself, and on the afternoon of the very day write to say that he cannot possibly attend—a sudden call to the country in one instance, a severe cold in another, illness in the family will prevent the third from bringing forward his contribution that evening, leaving to the Secretary at perhaps 5 or 6 o'clock p.m., the pleasant task of driving from house to house for substituted material. This should not be. When once a member has put down his name for a certain date, nothing whatever but an unavoidable cause should prevent the fulfilment of his engagement. He should regard it as a debt of honour due to the Society, which must be paid. This failing upon the part of members, I must say, has been less frequent of late, since the subject-matter to be brought forward, together with the name of the author, has been posted in the hall of the College, and announcement of the same been sent by circular to those living in and around the metropolis. This is but one of the labours that fall upon the Secretary, yet one, I think, sufficiently onerous to excuse me for mentioning it from the chair. Another adjunct to the efficient working of the Society, and a most necessary one, is the Publication Committee, *quorum pars magna fui* for I know not how many years. Now, gentlemen who take part in discussions but little know the difficulty that devolves upon the members of this Committee

in dealing with a *verbatim* report, each speaker being desirous of having the last word credited to himself, the acerbity of his opponent's remarks obliterated, but the sharp retorts upon his own side permitted to remain, and if this be not done that individual feels himself aggrieved. Again, speakers demand oftentimes proofs of what they have said, for the purposes of self-correction. This has been obliged to be forbidden by the Council, for some contributors would so change the wording of their speeches that the expense of altering the type was enormous to the editors of those journals who gratuitously publish the reports. The duty of the Publication Committee is, I repeat, onerous indeed, and responsible, and I assure you that now, when no longer engaged upon it, I am often surprised at the few errors these reports contain, considering the large amount of material to be corrected, and the very short space of time in which the revision must be made. So saying, I have only to express the hope that the members of the Society will always support those who have kindly undertaken the task, for it is indeed no easy matter to adjust for publication the report of a *warm* debate, so as to give to either party the credit they deserve from the force of argument advanced and yet erase those portions of each speech which they themselves might perhaps afterwards regret to see in print and yet to do so without weakening the force of argument on either side. That the members of this Committee can ever succeed in pleasing all parties will be impossible. They can only in the discharge of their duty *know no party*, and so acting, will, I feel certain, receive the general support of the Society. As regards the publication of the proceedings, the plan of printing them *in extenso* in the *Medical Press* and the *Hospital Gazette* week by week, as they occur, has, I think, a great advantage over any volume of transactions brought out annually or biennially. The first ensures not only rapid circulation, but frequently elicits from the readers of journals valuable comments and remarks which would otherwise never be made public. Weekly reports are for the most part read. Transactions but too frequently are put by for future reading—a future that never comes. The efficacy of these reports is further shown by the many quotations made from them, and which subsequently appear in the standard works of the day. For all these reasons I trust that the Council will adhere to the plan heretofore so successfully adopted, of publishing the proceedings *in extenso* in those weekly journals which have been so kindly placed at their service for this purpose. There is, in reference to the furnishing of communications, one point upon which I cannot avoid to remark, and that is the scant supply of matter which we receive from our fellow-labourers in the country, and the loss the Society thereby sustains. For this I can in part measure account, and in order to obviate its future occurrence, I would refer to it to-night. The reason will be best exemplified by the answers which as secretary, I so frequently received when speaking to country brethren on this point. "I have not time to write long papers" would be the reply of one; "I cannot 'work up' my cases and fit them for the Society," would say another; "I could only give cases just as they occur in my practice," would reply a third, "and that you know the members would not care to have." Would they not? Did they value, and do they value the Dublin Hospital Reports—those simply told truthful records of surgery and medicine as practically applied to the relief of injury and disease? I believe, gentlemen, that I shall be borne out in saying that what this Society desires to have at its evening meetings is terseness, contributions short and clear, and not borne down with a weight of learning—"simple in their narration, practical in their character, and devoid of speculative theory; while lengthened statements, elaborate tables, and laboured reports, with a ransacking of the literature of the profession for cases bearing similarity to that advanced by any author (as has been stated by a recent writer) are more suited for publication in monograph than for the meetings of our Society. With reference to the programme of business at each meet-

ing, I would beg to observe that, whilst recent specimens in pathology are allowed by the bye-laws of the Society to have a priority over all other communications, these specimens should be *bond fide* recent, that is to say, such as would suffer from delay in exhibition, and not morbid structures that have already been preserved in spirit, or otherwise, and that could well wait for their proper turn for being brought forward. In connection with this subject, too, I may mention that it is my intention to compel the exhibitors of recent specimens to abstain from alluding to the surgery of the case, because points may be mentioned upon which it might be desired by members to have discussion, and that is contrary to rule. I would next say a word or two regarding the Honorary and Association Membership of this Society. The Honorary Membership the Council purpose in future to bestow strictly in accordance with the original rule—viz., to elect as honorary members only such persons as shall be eminently distinguished by their labours and acquirements. "Honorary members," then, will be strictly limited to such, whilst the term of "Associate Member" will be conferred upon those whom the Council may elect to the honour, deeming them as likely to co-operate with the ordinary members of the Society in their efforts for the advancement of medical and surgical knowledge. And now, gentlemen, I have to speak of those who cannot be with us to-night—and it is indeed a painful duty—of those who for many, many years scarcely missed a meeting of the Society, who helped to found it, and who, indeed, assisted mainly in supporting its character as being the source of sound and practical information—namely, of William Hargrave and of Arthur Jacob, two men who were my colleagues for nearly a quarter of a century, two men honoured and respected by the College, whose portraits grace its walls, placed there in testimony of the able and faithful discharge of the duties of their professional chairs. Of William Hargrave, as the last taken from us, I would first speak, if speak I can, when friendship and the recollection of so many pleasing hours passed together fill the heart to overflowing, and almost stop the tongue from utterance. A good anatomist, and a sound opinion, his head and hand made him all that could be desired as a hospital surgeon. Who that saw the brilliant way in which he secured the common iliac artery, when seventy years of age, could help admiring his operative skill? whilst here, in this room we have all, or nearly all, been witnesses of his readiness in debate. To this Society he was warmly attached. No matter how inclement the weather, he came night after night to the latest period of his life to join in our meetings, and add to their value the experience of his extended professional career. The long array of medical students who slowly followed his remains to their last resting place—those oft-maligned, but noble fellows, who are always wont to give honour where honour is due—the number of his brethren who joined in that same procession, all showed by their presence the respect, esteem, and deep regard they felt for William Hargrave. Of him I can truly say that he was an honest man—that noblest work of God—and I shall not forestall by further observation those words, which will ere long be well, nay better said. And now, next on the death-roll stands the name of Arthur Jacob. What shall I say of him? He was an extraordinary man—and these words I use advisedly—because he was no ordinary man. As a colleague for so many years in that hospital which, I may truly say, he himself founded, I had full opportunity of knowing well his real character, his sterling worth. Those who were but slightly acquainted with him may have thought him brusque, but those who knew him well, as I did, speedily forgot his manner, and learned to look with admiration on his unflagging energy, his unchangeable honesty of motive. To the interests of this College I may indeed say he was devoted. He did all for it, whilst its Professor, that man could do, and subsequently gave his valuable library to the College. The series of exquisite anatomical preparations of the eye, both human and comparative, which he made with such labour, he presented to the Museum, and I have now to offer for the acceptance of

the College the drawings of the preparations made by that great master-hand of that membrane which, as long as anatomy lasts, will, I trust, still be known as the *Membrana Jacobi*. Preserved by him in recollection of his earlier life when he laboured in the field of anatomical investigation, the old man kept them as the very apple of his eye; but when Death approached to close those orbs, whilst he could still look upon them, he said, "Take those drawings back to Ireland, give them to the President of the College of Surgeons, and let them be presented in my name to that body." Gentlemen, I do so now. They are yours. It is Arthur Jacob who, though dead, yet speaketh. This is his gift. Will you kindly accept from me another memento in memoriam of him? It is a less pretentious, but in connection with the life of Arthur Jacob, perhaps hardly less interesting souvenir. It is the inkstand that from youth to age he used—a little earthen jar imbedded in a piece of lead—simple in construction, as the habits of the man who used it; solid on its base, as the information which to the world issued from his pen. The first and the last articles he ever wrote were with the ink which this jar contained, and with the pen so dipped he edited for years that journal which he started in defence of the medical literature of his country, and as an organ for the expression of Irish medical opinion. For man to toil more laboriously or more conscientiously than Dr. Jacob did would be impossible; nor have many men left behind as the result of their labours richer fruits than he. His work was continuous and persevering; his life one of devotedness to his profession and its interests. As regards self, his every act was self-sacrifice. And now, gentlemen, in conclusion, I will only say that the object, end, and aim of this Society are noble and praiseworthy, whilst the means it employs are wise and legitimate, and the advantages which it confers upon ourselves, the profession, and the public, are great and manifold. In the working of this Society, whilst our immediate aim is mutual benefit and professional advancement, we are in reality equally aiding our suffering fellow-creatures, bringing our combined knowledge to bear, through individual action, upon the community at large, giving (so far as is permitted to us by the Deity) powers over the health, and even life, of our fellow-man.

## Original Communications.

### WHAT IS DISEASE?

By EDWARD LANE, M.A., M.D. Edin.

It may seem at first sight a somewhat novel question to put as the heading of an article in a medical journal, "What is disease?" Do we not all know already (it may be asked) what it is in its multitudinous forms? Have we not all suffered from it at times from our infancy upwards? And is it not the duty of our daily lives as medical men to observe and report on it, to prevent, to mitigate, and wholly baffle it where possible? No doubt that is true; but having regard to a correct philosophy of medicine, with its important bearings on every-day medical practice, we think the question may not only be profitably asked as a matter of curiosity or theory, but as one of the very first importance, not only to the medical profession as a separate guild or calling, but to society generally. It is surely always wise to exercise a vigilant care over the foundations of the edifice we occupy, more particularly if it should be ancient, venerable, and the object of just affection; while it is also to be borne in mind that we live in a day of the world when the prying eye of criticism is busy everywhere, when the stability of all beliefs and professions is unsparingly ransacked, and every institution whatever is forced to defend itself at

the bar of the most searching scientific investigation. The fundamental question, then, for the medical art of to-day, on the right answering of which so much appears to us to depend, is, "What is disease—that condition of the system which we are constantly called on to deal with professionally? Is there any broad and general way of reliably accounting for it, so that possibly we may get at sound notions, not only in regard to its prevention, but its philosophical medical treatment?" The question, it may be stated at once, could not have been correctly answered before the birth and development of the science of human physiology—a science comparatively of yesterday, though no thinking physician will now for a moment deny that it constitutes the very ground-work of any system of medicine with the least scientific pretensions. What, then, is the chief lesson which modern physiology has taught us? Its office has been to explain the functions of the various organs of the human economy in the condition of health; and this explanation has naturally established a code of laws on the subject, now known as the *organic*, or *fundamental*, laws of health. They are fortunately neither very numerous nor difficult to understand, amounting, in fact, to something like this: In order to have health, the human being requires pure air to breathe; a sufficiency of plain but nutritious diet, pure water to drink, and to maintain his body in cleanliness, the proper amount of exercise necessary to digest his food and vitalise his blood, and finally, the brain and nervous system must not be subjected to overstrain, either through the operation of the purely intellectual processes, or through the agency of the passions and emotions, whether of pleasure or pain, that belong to our moral nature. The above, very shortly stated, may be taken to constitute the fundamental laws of health as laid down by physiology.

Now, when we have arrived at this point, we are led by a very simple step in logic to the irresistible conclusion that if the observance of the above organic laws leads to health, the non-observance or violation of them will as surely lead to non-health, or disease. And, in fact, so it is. If, looking beneath the surface, we inquire narrowly enough into the real cause of the diseases that afflict mankind, we shall find that, putting aside accidents on the one hand, and the maladies directly springing from contagion and from the vicissitudes of heat and cold on the other, it is to the breach of the laws of health that the long array of ills that flesh is heir to is in the main to be ascribed. For scientific purposes, therefore, the question with which we started may be regarded as already answered; and it is something to have got that length, and to feel that we can repose on so firm a physiological basis in regard to this most important doctrine.

But the practical value of such a conclusion is no less immense, as we conceive, to the interests of medicine as a profession, than to those of the public. For the profession, it may be said to open up a new and comprehensive philosophy, both of disease itself, and then of its natural treatment. Perceiving now clearly how disease is chiefly occasioned, we arrive with this knowledge at once at the preponderating importance of prevention, when hitherto we have occupied ourselves almost exclusively with cure, as the medical man's only special and proper business. In other words, we are brought face to face with the subject of hygiene—immense, and immensely growing—a department for the advancement of which the public look to our profession as the natural ministers of health. And then as to the matter of treatment. There is no use shutting our eyes to the fact that, for many a long century, the treatment of disease was both barbarous and childish, from want of the power of correct diagnosis, but perhaps even more, at least in more recent times, from the absence of any true view of what disease really was, and how it was generally produced. Physiology has now come in as our guide, not merely as to the most frequent cause of diseases, but no less as to their rational treatment. It makes it clear to us that when the fundamental laws of health are broken, in whole or in part,

disease, in one form or other, is sure to ensue, and the inference is irresistible that the true and strong position of the medical art consists in this: to battle, with every means which science has put in our hands, to *prevent* disease, and when that has failed, to endeavour to *treat* disease intelligently, by studying with the most careful accuracy the distinguishing features of each complaint as it presents itself, relieving and palliating on all occasions to the very best of our ability, with all the means experience has placed within our reach, without, however, forgetting the *nexus* that binds all diseases together, in regarding them all as a penalty of the broken laws of health, and constantly endeavouring, as the most important by far of all therapeutic measures, to bring back the patient to the implicit observance of the laws of health so violated. The best minds in the profession, both here and abroad, would seem to be travelling undoubtingly along that road, with the sunlight of reason lighting up the way.

### REPORT ON SYPHILIS.

By C. R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.,  
Senior Physician to the Metropolitan Free Hospital.

DR. ALFRED FOURNIER ON TERTIARY SYPHILIS (*continued*).

DR. ALFRED FOURNIER thus continues his important lectures (*France Médicale*, 19th August):—

IV. *Diagnosis of Uterine Syphilitic Affections*.—In the diagnostic study we are pursuing, a second point, and that quite a special one, ought to arrest us now.

I have told you that tertiary syphilitic affections may be implanted even in the neck of the uterus, and that even there they are not absolutely rare, and I have given you numerous examples of this. Now, these lesions are exposed on the cervix, more than elsewhere, to be mistaken as to their nature, and confounded with accidents of another kind. The proof is that up to this day tertiary lesions of the cervix have not been specially described, and that they are not even indicated in the most recent classical treatises.

It will not, then, be devoid of interest to insist on the diagnosis of this order of lesions. Let us see with what accidents they may be confounded, and seek how we may distinguish them from such.

1. *Mucous Metritis*.—In the first line there present themselves quite naturally here, inflammatory ulcerations of the cervix resulting from what is called mucous metritis, common lesions, generally spoken of as catarrhal ulcerations, granulations, &c.

There is no doubt but that in the majority of cases ulcerated syphilitic affections of the cervix are confounded with those ulcerations simply inflammatory, very variable besides in extent and aspect, and yet ill-defined in character. Yet, when we descend to details, we see ulcerated syphilitic symptoms presenting certain characters which are not presented by the inflammatory ulcerations, or reciprocally; and that, thanks to these characters, they may often (I do not say always) be separated from them with certainty.

Thus: 1. Ulcerated syphilitic symptoms are generally more hollowed out, notably more hollowed out than the inflammatory ulcerations, which, to say the truth, consist very often in erosions rather than true ulcers.

2. They are less granular, more polished, and flatter at the base.

3. The edges are more marked, higher, more cut, true borders, in a word, whilst the inflammatory erosions are almost level with the healthy tissues of the cervix.

4. They have sometimes a contour composed of segments of circles, which is never the case with the inflammatory ulcers.

5. They radiate from the orifice of the neck less regularly than the inflammatory ulcerations, which radiate in general in an eccentric and irregular way from this point.

6. They are not accompanied, as the inflammatory ulcers are in many instances, with swelling of the cervix, uterine hypertrophy, morbid sensibility of the organ, neuralgic peri-uterine pains, menstrual disorders, hæmorrhages, &c. In a word, whilst the ulcerations of the cervix, when inflammatory, are for the most part ulcers on a uterus which is diseased to a certain degree, the ulcerated syphilitic symptoms are, on the contrary, ulcerations on a healthy uterus, except in cases of morbid contingencies.

7. They are, lastly, far more easily resolved than are the ulcers of metritis. These last are, in general, obstinate, and obstinate because they are symptoms of a disease of the uterus. Ulcerated syphilitic symptoms, on the contrary, which affect the uterus, are generally cured pretty quickly and pretty rapidly, with the slightest care, such as by touching them with nitrate of silver, dressing them, &c.

These considerations, joined to the notion of the antecedents, or better still, to the presence of ulcerated syphilitic lesions on the vulva, often clear up the diagnosis in a very precise manner. Should they be sufficient, which happens only too frequently, they permit at least, if not to affirm, at any rate to suspect, the specific nature of these lesions. Now, this is everything, as far as essentials are concerned, as far as the most practical point, prophylaxis.

To a woman, indeed, affected with inflammatory erosion of the cervix, we may rigorously permit relations within certain limits, for these relations in such conditions are not dangerous for others.

But to a woman affected with ulcerations of the cervix of syphilitic nature, connexion should be absolutely forbidden, for these ulcerations are certainly contagious, and by contact with them the male risks inoculation with a grave disease—syphilis.

The essential is, then, here to suspect simply the nature of these lesions, to forbid connexion, and to treat the contagious lesions as quickly as possible, to cut short in this way the possibility of the dreaded contagion.

In the second place, ulcerated syphilitic affections of the cervix may also be confounded with simple chancre on the same place. I only mention this fact here, having insisted at length last year on the differential diagnosis of these two lesions.

**V. Diagnosis of Phagedænic Lesions.**—Lastly, gentlemen, a final chapter remains to be opened by me as to the differential diagnosis of tertiary syphilitic symptoms of phagedænic nature; and this chapter is assuredly neither the least difficult nor the least important of those we have treated hitherto, as you will see.

Phagedænic genital syphilitic affections are exposed to be confounded with the two orders of phagedæna which are seen on genital organs—1st, with the phagedæna of the chancre, and almost exclusively of the simple chancre, since the syphilitic chancre but very exceptionally is attacked by phagedæna; 2nd, with scrofulous phagedæna.

1. Let us just speak of chancrous phagedæna, or that resulting from the simple chancre.

It is certainly a diagnosis not easy to make out when a phagedænic ulceration has eaten away a part of the penis or of the vulva. What is this ulceration? Is it phagedæna due to simple chancre? Is it due to tertiary syphilis? The thing is difficult to specify in many cases.

Doubtless we have the antecedents to enlighten us. The patient has or has not had syphilis. That is essential to know, and that alone may suffice to throw immediate light on the diagnosis. But, first of all, these antecedents may be wanting. How often do we not see, in women especially, some syphilitic affection without any history of special kind, without antecedents. This is a point on which I do not need further to speak after what I said in our last meeting.

Besides, these antecedents are far from always having a precise signification. The patient, I suppose, has had syphilis; he confesses it, or even presents at the moment evident phenomena of it. But is accumulation not per-

mitted? What, will you not admit that the patient, already syphilitic, may not have besides contracted a simple chancre? The thing is not rare, especially here, and many of the women of this hospital are affected at once with syphilis and simple chancres, without preventing them having still other venereal symptoms.

Hence, the syphilitic antecedents (except in cases where the patient has not been exposed to the chance of adding a new contagion) are silent against the possibility of a simple chancre being the origin of the phagedæna. This is precisely the difficulty. But some will say, if the antecedents and commemoratives do not throw light on the nature of the lesion, at any rate, the diagnosis may be made by the objective symptoms. The objective symptoms are scarcely of any value, gentlemen. All phagedæna cases are similar at a given moment; and that which the most attentive examination and minute inspection of the areola of the ulcer, as to its edges and base, can furnish, for the most part only ends in differences greater or less, true shades which have no significance. I have already seen many cases of phagedæna. Well, I declare to you, and that contrary to many authors, I have but very rarely been able, very exceptionally to be informed by objective characters as to the nature of the lesion.

Other symptoms derived from the evolution and from complications may better enlighten the diagnosis in certain cases.

Thus, the simple chancre is a lesion ulcerated from its commencement, which is born in the ulcerated condition, and has been only an ulcer in all its course. Tertiary syphilitic affections, again, arise in the form of tumours, sometimes of solid nature, which soften later on. When they are gummy tumours they have at their commencement a dry period, which may be misunderstood, doubtless, but which is not so always necessarily misunderstood. This is a diagnostic element.

The simple chancre presents complications more frequently than tertiary syphilitic affections do. It is more inflammatory in appearance, more acute in its progress; it suppurates more, is more complicated with inflammatory symptoms, with balanoposthitis, simple or gangrenous, with phymosis, paraphymosis, vulvar œdema, abscess, &c. It is also more extensive, and tends to propagate itself beyond the vulva or penis.

But these complications are still only eventual. When they exist we may derive assistance from them; but when they do not exist (and they are often absent) nothing can be inferred from this, of course. Besides, did they exist in the highest degree, they have still nothing absolutely significative. They form elements of probability, not of certainty.

Let us, then, pass over these different considerations, and proceed straight to the true elements of a formal and absolute diagnosis.

Between chancrous and tertiary phagedæna, I see, in short, but two differential signs clearly and peremptorily characteristic. These two are—

1. The existence of the *chancrous bubo*, to which we may join as annex the chancrous lymphangitis.

2. The data of inoculation.

What indications do these two symptoms furnish?

1. *Chancre Bubo*.—If the ulcer we speak of has been complicated, or is actually complicated by what is called a chancrous bubo (that is to say, a bubo which has a chancrous suppuration, an intra-glandular inoculation, a true inguinal chancre), then the diagnosis is formal and absolute; for the simple chancre alone determines this kind of bubo. The chancrous bubo discloses the simple chancre as its origin. It is the witness, the demonstration of it, as I have established in our conferences last year.

But, again, the chancrous bubo is but an eventual accident of the chancre; it even is more frequently absent. This is not, then, yet a symptom on which we can count.

As a last analysis, there remains, in difficult cases, but one element of diagnosis. But on this we may always build, for we have it always at our call, and may always

consult it; it is inoculation, auto-inoculation, of course, which is the only permissible one, the only lawful and the only moral kind of inoculation.

## 2. Inoculation.—What does this furnish?

This: Inoculate the pus of a chancreous phagedæna. You produce a simple chancre, with the formal and irrefutable characters of the simple chancre, which I have spoken about to you. Inoculate the pus of tertiary phagedæna. No result occurs, the inoculation remaining sterile, or negative. Ah! here at last is a symptom, a precious one, a true criterion; here is a symptom which may enlighten us in doubtful cases.

The formal diagnosis of chancreous phagedæna and tertiary phagedæna resides, and resides only in inoculation.

But here, gentlemen, an observation ought at once to be made. Reflect well that we have not to do, in the case before us, with an ordinary inoculation, with an inoculation in the ordinary condition, when this experiment is practised. It is not only a chancre the pus of which you are inoculating in such cases, but a phagedænic chancre. Now, this phagedænic chancre may more than any other, better than any other, reproduce a phagedænic ulceration. Of course, this experiment will not of certainty produce a phagedænic chancre; for, if this were so, not only would I not propose the inoculation to you as a method of diagnosis, but I would forbid you to make use of it, I would consider it my duty to forbid it, and to forewarn you against the attempt at such practice. But again, besides the condition of the person, and besides the nature of the lesion from which the pus is taken, there are risks that, practised in particular conditions, the inoculation may become the origin of a phagedænic ulceration. Thus, on the one hand, we should be as sober as possible of this mode of experimenting; we ought even to refrain from using it unless there be immense importance for the patient that we should be certain as to the nature of the ulceration, and if we have scientific inductions which prejudice negatively the result to be obtained. On the other hand, if we decide to practise inoculation, we ought to proceed to it with more care and precaution than usual, and, especially if the pustule be produced, we should destroy it immediately, by the most energetic procedure, without giving it the power or leaving it the time to extend. Cauterisation with sulphuric acid mixed with charcoal dust (the carbo-sulphuric caustic of Ricord) is here the simplest and the surest at once.

Still, as a counterpart to what I have just said, I would add that there are cases where the utility of this inoculation is such, where there is everything to gain for the patient, that a precise diagnosis should be commenced as to the lesion, that the inoculation becomes then not only lawful, but necessary. We ought then to persuade the patient to use it (a consent indispensable for the dignity and the security of the practitioner), and having obtained his consent, we may boldly practise the inoculation. For on this and this alone may depend the diagnosis, and with the diagnosis, the treatment. To convince you of this, I will mention the following case, which struck me forcibly some years ago.

I had occasion to be consulted by a patient who for two years had been treated for a supposed simple chancre of the penis. This chancre, after destroying a good half of the gland, had attacked the prepuce and partially removed the covering of the corpora cavernosa. It was going on, always progressing. Nothing had affected it up to that time. After having for long examined this hideous wound, I thought by certain signs that I could recognise a phagedænic syphilitic tertiary affection, although the patient denied having had syphilis, and asserted that he never had had any venereal accident but this. Not having been able to bring the doctor who was treating it to agree with this diagnosis, I proposed inoculation to set the debate at rest, judging beforehand that this experiment would have a negative result, consequently, inoffensive and very useful by the light that would arise from it. Refused at first, the inoculation was accepted two months later, when the ulcer

had made further progress. As I had announced, the inoculation was negative. On this indication, specific treatment was then commenced, and I am glad to say it was followed by a rapid success.

Observe what assistance inoculation may offer in like cases to the practitioner, and especially to patients.

2. Some words, finally, as to *scrofulous phagedæna*. Scrofulous phagedæna attacks the penis quite exceptionally. I have as yet seen but one or two examples of it. In revenge for this, there exists in women an affection of the gravest and most hideous kind, which develops itself under the influence of scrofula, and which reproduces upon the genital organs, sometimes also on the anus, the lupus of the face. This affection you have already guessed: it is the lupus of the genital organs, scrofulous lupus of the valva, *esthiomène*.

I am not about to trace for you here the symptoms of this affection, which you will find marvellously described either in the original memoir by M. Huguier, or in the recent article of M. Bernutz ("Nouveau Dict. de Méd. et de Chir. Prat.," xxix.) By a word, I will remind simply of its principal traits in thus observing, that it is the scrofulous lupus of the genito-anal region. Transport, indeed, lupus of the face to this region, with its tubercles, its ulcerations, and hypertrophies of tissue, its destructions, perforations, &c.—transport this, with all its *cortège* of hideous symptoms and mutilations, and you will have exactly the representation of what genital lupus in women consists.

It is, consequently, useless to say that this lesion is objectively similar to tertiary phagedæna, and may be confounded with it, or reciprocally. It is also useless to add whether it is necessary or no to establish a precise diagnosis as to lesions so grave as this. Let us then, in a few words, try to trace the differential diagnosis of these two pathological types.

The objective symptoms of the lesions we are about to compare present without doubt a certain number of differences. Thus, vulvar scrofula has generally a contour more irregular and sinuous, more uniforn, as M. Huguier says—it has its edges less vertically stamped, less sharply cut, more inclined by a gentle slope towards the base of the lesion; it has a redder base, more violet in colour, and more villous; it secretes less, and rather sanious serosity than pus, &c. But there are, after all, but slight differences, often of little significance, and subject to variation, and upon which we cannot base, in many cases, to institute a differential diagnosis.

Something more characteristic is offered by the coexistence in certain cases of certain small vegetating tumours with the scrofulous ulcer, tumours pisiform, mammillary, sessile, wart-like, which are produced either on the non-ulcerated skin, or on the surface even of the ulcer (vegetative form of *esthiomène*). But this is only again a chance symptom, a particular form of the disease, and has nothing constant about it.

On the other hand, a better sign, and one I recommend to the attention of you all, because it has struck me greatly in several cases, comes from the condition of the parts which surround the ulcer.

These parts (and it is especially in the labia majora that this is remarked) present a state of soft swelling, with rose-lilac tint of the integuments. The labia majora are swollen, and as if hypertrophied; these neither œdematous nor brawny, nor indurated, as in common sclerema. They are at once swollen and softish. Their cutaneous part has a morbid suffusion of a rather special tint, a rose-violet tint, with parts covered with a slight brawny desquamation.

Hence arises a rather special appearance—an appearance hardly describable, which must be seen to be well convinced of, and which gives to the lesion a truly rather distinctive appearance.

The evolution and progress of the lesion also present diagnostic points useful to consult. Thus, vulvar scrofulous lupus has a very slow evolution, much slower than tertiary phagedæna. Its progress and destruction take place only in months or years, so that, examined at

intervals of some weeks, the lesion seems almost stationary.

It is besides a phagedæna, which takes place on the spot, which has little or no expansion, remaining confined to the vulvo-anal region, not as with certain cases of tertiary phagedæna which pass away from the vulva to the abdomen and the inguinal regions.

Besides these two orders of signs, others more general and more certain are again furnished by some considerations of a different nature, namely, the examination of the constitution, the morbid antecedents, actual accidents, and from the results of treatment.

The examination of the constitution, of the antecedents, and of actual accidents will teach you if, yes or no, the patient is afflicted with the scrofulous diathesis, and if she has had, or still has non-equivocal manifestations of it; if, yes or no, she has been formerly affected by syphilis: It is useless to insist on the considerable value of these pieces of information, which are first of all to be looked for for diagnosis.

But have these pieces of information always an absolute value?—do they always suffice to clear up the diagnosis in an absolutely peremptory way? Yes, in the majority of cases; no, in a general fashion. We must not, in fact, neglect here the two following points of view.

Firstly, if vulvar scrofula most frequently appears in scrofulous women, that is, clearly so from their antecedents and actual habits, we have seen it also produced in women of middle constitution, not having presented any previous symptom of scrofula.

More than this, syphilis may be added to the scrofula, may arise on a scrofulous soil. Hence morbid influences and complications, which are not easily separated.

In the last place, the treatment remains, which, especially here, more than elsewhere, may serve as an element in the diagnosis.

There are, first of all, cases where the diagnosis, which at first sight was doubtful, is quite naturally established in some days under the influence, not of treatment, but of simple hygiene.

Sometimes, on the first day of the arrival of the patient in hospital, it is perfectly impossible to know with what we have to do, such is the hideously confused condition of the lesions. But in a few days after, when the patient has been washed, bathed, dressed, rested, and carefully tended, the lesions change in appearance quickly, become modified and transformed as by magic, and the diagnosis of syphilis can be made by this fact alone.

It is indeed nearly alone in syphilis that we are permitted to see these quick transformations. Vulvar scrofula, by general confession, is far more obstinate and far more refractory.

*A fortiori*, treatment has an influence yet more significant, after an interlude of some weeks.

If the lesion be syphilitic, in some weeks it generally undergoes a curative influence, evident and manifest, under specific treatment.

Doubtless there are exceptions to this rule; doubtless tertiary phagedæna has also its rebellious cases: but this is the rarer case. The common fact, on the contrary, is the rapid amendment of tertiary lesions under the influence of the treatment.

If, on the contrary, we have to do with true vulvar esthiomène, hygiene and anti-syphilitic medication do not modify it; the anti-scrofulous treatment even remains without action upon it: we only modify it with extreme slowness, almost desperately so; most generally it even remains absolutely useless.

So that the diagnosis, if it sometimes remains at first undecided, rarely remains unfinished when treatment is tried.

Such, gentlemen, is the collection of the signs which permit us to distinguish phagedænic syphilis from scrofulous phagedæna.

(To be continued.)

## CHOLERA: ITS ÆTIOLOGY, CONTAGIOUSNESS, AND TREATMENT.

By WM. BOYD MUSHET, M.B. Lond., M.R.C.P.,  
Late Physician to the North London Hospital for Consumption, formerly  
Resident Physician at St. Marylebone Infirmary.

### ÆTIOLOGY.

(Continued from page 456.)

Now, with regard to Dr. Johnson's first proposition, which is an adoption of the prior views of Dr. Baly and Sir Wm. Gull, no evidence is adduced in support of the assumption of the materiality and portability of the cholera poison, and of its communicability from person to person. These hypotheses *may* be correct, but they prove nothing as to the specificity and contagiousness of the poison of cholera, and they are directly at issue with the belief of some of the highest authorities on the subject. As to the proposition that the poison is absorbed into the blood, similar objections will apply to those raised in reference to the preceding; but this will be more clearly considered in the sequel.

Dr. Johnson's proposition that the discharges are a conservative effort, similar to the eruption of variola, and the diarrhoea of typhoid, is founded on a most erroneous analogy; as, if there be any resemblance in the morbid processes, we should promote the eruption of small-pox by heat and diaphoretics, as eliminants, and administer cathartics in typhoid for a like purpose. Again, would the most strenuous attempts at elimination cut short the two latter diseases, *i.e.*, arrest their further course?

If we admit, with Dr. Johnson, that the cholera poison is as drastic a purgative as any in the *materia medica*, and that this "cholera-cathartine" must and will purge itself away—is it therefore to be aided by further purgative efforts? As well may we attempt to treat a case of excessive evacuation from elaterium with castor-oil, instead of striving to control the discharges by opium, sedatives, and astringents. But Dr. Johnson will doubtless reply, that in cholera we have "zymotic" changes in the blood, and not after a dose of elaterium; but I maintain that the presence of such changes is equally problematical in the former as in the latter, and that it is less rational to expose the patient to an undisputed *hypercatharsis* than to the risks of a highly questionable *zymosis*.

Dr. Johnson allows that the discharges may be so copious as to kill. This is admitted even by Dr. Johnson, who yet declares that the discharges bear no direct relation to the degree of collapse, that they are not the essential or chief cause of this, as collapse and death may occur without discharges, and with but scanty secretions into the bowels. Such cases are very, very rare, to say the least, even in India (see *Lancet*, June 2nd, 1866), as Drs. Parkes and Goodeve never witnessed a fatal case of cholera unattended with vomiting and purging, though, it should be added, that Dr. Parkes regards them as usual, but not essential symptoms, and thinks it probable that cholera might occur entirely divested of these symptoms. In England such cases are even more rare (has Dr. Johnson ever witnessed one?), and almost every one who has seen much of cholera admits that the evacuations are ordinarily in direct ratio to the collapse. Thus, of 1798 cases of collapse reported to the Board of Health in 1854, all but 6 were attended by intestinal discharges, and in these exceptional instances it is stated that more accurate inquiry would most probably have elicited the fact that some intestinal flux occurred before the phenomena of collapse were developed. Physicians seem to have overlooked to some extent the variations in constitutional power and in the previous state of health of persons attacked, consideration of which would in most instances explain apparent anomalies. It is well known that some few persons will become collapsed, and almost succumb to two or three ordinary diarrhoeal evacuations, on account

of feeble vital power, inherent debility, nervous idiosyncrasy, or existing cardiac disease. Such persons, it may be said, live on sufferance, requiring little disturbance to snap the thread of life. How unequally do different individuals bear operations, chloroform, pain, and other mental and physical shocks, many of whom, previous to the fatal seizure, have manifested no marked peculiarities, and provoked no particular medical attention! Now and then a patient will die from mere fright, the sting of a wasp, a crushed finger, or faint from the slightest causes.

Moreover, in these cases of "cholera sicca," did Dr. Johnson even perform an autopsy, or hear of one having been performed, in which there was neither vomiting nor purging from the commencement to the termination of the case, and in which the intestinal tube was devoid of exhalation?

Dr. Johnson not only disregards the dangers of the premonitory diarrhoea, but promotes the symptoms by castor-oil. It is not too much to say that, in cholera periods, a person with slight relaxation of the bowels is, in the opinion of Dr. Johnson, in a more desperate condition than a patient actively *αὐτὸ καὶ κατὰ* evacuates. And yet, with singular inconsistency, this physician allows that the "abundance of the gastro-intestinal excretion is a pretty accurate measure of the severity of the attack"—the excretion which he is desirous of aiding and augmenting in defiance of its physio-pathological significance. Again, he says, "no cases are more hopeless than those in which there is not only a cessation of vomiting or purging, but an almost complete arrest of the process of excretion from the gastro-intestinal canal." That is, that the patient has least chance where the drain has been so abundant as to leave nothing more to be exhaled, thereby confessing that the choleraic discharges tend in proportion to their severity to induce irretrievable collapse.

Dr. Johnson's explanation of the phenomena of cholera is that there is a spasm or contraction of the minute pulmonary arteries, caused by a morbid poison in the blood, which acts as an irritant to the muscular coat of the vessels. Here Dr. Johnson argues from facts to hypotheses, as the lividity, fall of temperature, and purgation can be otherwise better explained; and the imaginary morbid poison is a sort of *Deus ex machina* introduced to account conveniently, but imperfectly, for the arterial spasm, which is limited, as far as can be discerned, to the pulmonary vascular radicles, though the phenomena point to impeded circulation in every part and organ.

We search in vain for enlightenment why the pulmonary vessels are alone subject to the irritant action of the oft-invoked poison. This view of muscular contraction, spasm, obstacle, difficulty or thickening appears to be a hobby of Dr. Johnson, as he applies it to the explanation of Bright's disease, apoplexy, epilepsy, and cholera. Indeed, he defines cholera collapse as pulmonary epilepsy! (*British Medical Journal*, March 21st, 1868). This is a revival of the pathology of Cullen, a recurrence to spasm of the vessels ingeniously spun out to a most sophistical tenuity. As a sample that these observations are not unfounded, Dr. Johnson, in a communication to the *Medical Times and Gazette* on July 2nd, 1870, as to the proximate cause of hæmorrhage into the brain in chronic Bright's disease, maintains that it is due to "hypertrophy of the left ventricle, resulting from excessive contraction of the minute systemic arteries, which impede the onward movement of the blood, thus calling for increased efforts on the part of the heart to carry on the circulation. The muscular walls of the minute arteries are much hypertrophied as a physiological result of long-continued overaction. The struggle between excessive cardiac force and excessive arterial resistance increases the risk of hæmorrhage consequent on rupture of the minute arteries." This dictum is, nevertheless, controverted by a quoted case in which "the arteries of the pia mater presented no appearance of hypertrophy;" and Dr. Johnson thinks it probable that in this instance the cerebral hæmorrhage resulted from rupture of the capillaries, and that the

immediate cause of this rupture was excessive pressure of the cerebral capillaries, due to the fact that the propelling force of the hypertrophied left ventricle was *not* counterbalanced by an equivalent hypertrophy and consequent resisting power in the minute cerebral arteries; or, in other words, that the hypertrophy of the minute cerebral arteries, if present, is held to account for the hæmorrhage, and when absent, is equally called upon to explain its occurrence, to the exclusion of atrophy and degenerative changes. Dr. Johnson has observed in cases of chronic Bright's disease, with hypertrophy of the left ventricle, that, as a rule, the minute arteries in all the tissues examined, as kidneys, pia mater, subcutaneous tissue, muscles, mucous membrane of the bowels, have their muscular walls hypertrophied. Yet hæmorrhages into the kidneys, pia mater, subcutaneous tissue, muscles, and intestinal mucous membrane are singularly rare.

In cholera the spasm is most intense, the contraction of vessels greatest after the most evacuation, where there is, according to Dr. Johnson, the least poison remaining in the system. He thinks the collapse due to the contraction of the pulmonary arterioles, and that thickening of the blood is not the cause, but rather the consequence of the collapse. But it is in greater agreement with physiological truths to believe that the collapse, failure of circulation, and inspissation of the fluids are in direct proportion to the discharges and to the *arrestment of nutrition*.

There is, says Dr. Johnson, a primary asphyxia, a secondary apnoea; but, if asphyxia, why not coma, which is invariably the result of ordinary interference with respiration? And, as he explains the absence of syncope in cholera by supposing a venous turgescence of the brain, his difficulties increase in endeavouring to account for the non-occurrence of comatose symptoms. In other words, Dr. Johnson tells us that there is a condition of asphyxia, although the brain is clear, and the freedom from coma depends upon a primary asphyxia *plus* a venous turgescence of the brain! Dr. Johnson entirely overlooks physiological nutritional considerations, and makes cholera to be due to non-absorption of oxygen by the lungs. His doctrines are mechanical, to the exclusion of chemical, of vital changes. It appears to be a more satisfactory theory than that of pulmonary arterial contraction to ascribe the phenomena to *failure and gradual arrest of the nutritive forces*, however much we may differ as to the cause by which the effect is accomplished. According to Dr. Parkes, "patients die because the blood does not pass through the lungs, produced by some aberration of, or impediment to, the proper respiratory changes." In short, there is no nutrition, therefore no carbonic acid formed, and hence no necessity for respiration. Dr. Parkes truly said before Dr. Johnson that we must look to the *blood itself* for arrest of the pulmonary circulation. The blood is no doubt equally arrested in the capillaries of other parts of the body, owing to the *arrest of nutrition*; there is, in consequence, little or no need or power of circulation, little or no formation or evolution of carbonic acid, and therefore no requirement for oxygen and respiration. Parkes has noticed collapse of the lung in cases of consecutive fever in post-mortem examinations. Such appearances might be reasonably expected, as occasional, like the atelectasis of the newly-born if weakly, or the pulmonary collapse witnessed after fatal cases of pertussis, where the child is too feeble to expand the lung after violent expulsion of the residual air. In these cases of consecutive fever, the appearances are the result of the algid stage, expansion not occurring after reaction in consequence of the debility of the patient.

The diminution in temperature, the shallow respiration, the mahogany blueness of the surface must depend upon deficiency of oxygen and of oxidation in the system. There is no *besoin de respirer*, as there is little or no chemical change—no carbonic acid is formed in the extreme parts, and we know the respiratory function or necessity is merely for the purpose of elimination and interchanging carbonic acid for oxygen in the lungs. We also know that the temperature is proportionate to the

activity of the nutritive processes. Hence the shallow breathing—as there is no carbonic acid to exhale, no oxygen to absorb—the decreased animal heat, the darkened blood, which last, on account of the discharges, gradually becomes inspissated and stagnant from non-aëration devitalization. Hence also the collapse of the lung, in many cases, from imperfect expansion, which also occurs, as I have stated, in young children, as a result of pertussis and inability to draw in air for complete reinflation. Hence also the systemic collapse, the suppression of urine—as there is no disintegration of tissue—and of bile also, in most instances. There is absence of sensorial disturbance, as there is no poison in the blood, no effete material, no formation of carbonic acid, to complicate matters; but there is an apathy, an unconcern in the algid stage, as we might expect, as a consequence of cerebral centres imperfectly supplied with blood—circulating languidly in the vessels. But patients can speak feebly, and are usually conscious up to the period of dissolution.

Again, there is not extreme exhaustion in cholera until the last, as venous or imperfectly (oxygenated) arterIALIZED blood stimulates the muscles (Brown-Séquard). The heart, therefore, as a muscle, acts tolerably well, as does the general locomotive system, even when the patient is cold, haggard, with sunken eyes, Hippocratic face, and corrugated skin, which train of symptoms last enumerated depends in a measure upon withdrawal of fluid from the vessels by the discharges. On this account, partly, as well as from diminished blood current—no carbonic acid seeking egress—are noticed the emptiness, dryness, and lightness of the lungs of those dying in collapse. The change, if present, is only physical, not vital nor causative. Little or no blood is sent through the lungs, as little or no carbonic acid is formed in the general capillaries. Probably other organs weigh less—though the lungs may be expected to show this most markedly—as the whole body must be lighter in weight if drained of its fluids, and if the whole body, each, or most of its parts.

(To be continued.)

## Transactions of Societies.

### MEDICAL SOCIETY OF LONDON.

MONDAY, DEC. 14TH, 1874.

F. J. GANT, Esq., F.R.C.S., Vice-President, in the Chair.

MR. WILLIAM ROSE brought forward a case of cleft palate on which he had operated successfully. The patient, a young man, æt. 23, came under his charge about three months ago. He had a fissure extending through the soft and hard palate, to within half an inch of the alveolar ridge. He spoke of the development of the upper jaw and palate, which he illustrated by diagrams, and suggested a plan of bringing the maxillæ together immediately after birth in cases of very wide cleft. He described minutely Sir William Ferguson's new method of operating for simultaneous closure of fissure in the hard and soft palate (a drawing of which was shown) by boring holes through the margin of the hard palate for the passage of the threads, and then cutting through it with a chisel in a line parallel to and about half an inch from the edge of the cleft. By this means the edges of the cleft in the hard palate could be approximated. After dividing the levator palati muscle on each side, and carefully paring the edges, stitches could be passed through the holes in the hard and through the soft palate, and the edges brought into apposition in the median line. He demonstrated a new way of passing the threads. He spoke of Sir Wm. Ferguson's introduction of myotomy thirty years ago in the treatment of fissure of the soft palate as having quite revolutionised staphyloraphy, and expressed his firm belief that the recent introduction of osteotomy in the treat-

ment of fissures of the hard, by Sir Wm. Ferguson, would rank high as an operation among the numerous contributions to practical surgery of the eminent surgeon. He also stated that Sir Wm. Ferguson, when he published a paper on the subject last April in the *British Medical Journal*, was not aware that any other surgeon had suggested such a course of procedure. It was, however, shown that Dieffenbach, in his "Operative Surgery," published in 1845, had proposed a somewhat similar operation; but there was no evidence to show that he had ever performed it on the living subject, and his successor, Baron von Langenbeck, had never adopted the suggestion. He added that Sir Wm. Ferguson had operated on more than forty cases by the new method of dividing the bone, and that in all the palate was improved, and that two-thirds of the cases were successful.

MR. HENRY SMITH said that thirty years ago he had written out Sir Wm. Ferguson's original paper, in which staphyloraphy was mentioned, and had also assisted in most of that eminent surgeon's operations since. In the early ones, operation on the soft palate alone was attempted, and the results were not so favourable as under the new plan of osteotomy. Our Transatlantic brethren thought so little of staphyloraphy that they divided the soft palate afresh, and applied obturators. Mr. Smith considered that the natural coverings were far superior to artificial ones, and thought Mr. Rose's case was thoroughly successful, the fissures in the hard and soft palates being completely closed, which was a better result than had been achieved in his case, exhibited at the last meeting of the Society. Surgeons who proposed operation in these cases must be prepared for severe hæmorrhage, on account of the vascularity of the palate; this might be stopped by ice and other means; neither had it ever been known to be fatal. He dwelt at some length on the advantages of the gag, which enabled surgeons to undertake operations that had been almost impossible before.

MR. OAKLEY COLES stated that it was the surgeons of America, and not the dental surgeon, who slit up previously closed and soft palates to introduce artificial structures. He considered, however, that surgery would accomplish much in this field, and that the time was coming when the mechanical treatment of cleft palate would be obsolete. The great drawback in the surgical results was that the patients seldom spoke intelligibly; he only remembered one instance where speech became perfect after the operation; and failure was attributable to the fact that the free border of the soft palate in these cases never reaches far enough back to touch the pharynx to act as an effective valve, and here the mechanical appliance is far more successful.

MR. THOMAS BRYANT said that, after reading Sir W. Ferguson's osteotomy paper, he was at first sceptical, but now considered the operation a great advance. He wished to know whether, in the infant, silver sutures had actually been passed through the maxillæ to bring the fissures together. Of the old operation on the hard palate more than half had failed. How many of Sir W. Ferguson's forty cases were successful? There was no difficulty in piercing hard or soft palates, but in passing the stitches through, on account of the bleeding. Mr. Bryant introduced the stitches first, which facilitated matters, and reduced an operation of half-an-hour to a few minutes. He had some doubts as to the dividing of the levator palati muscle in every case, but thought a division of the pillars of the fauces was an improvement.

MR. ROYEN BELL complimented the author on his skill, and stated that the speech in this case, though varying, continued to improve. The patient could sing. The hæmorrhage in these cases was much less than formerly.

MR. FRANCIS MASON remarked that Sir Wm. Ferguson's success was greater since he had divided the bone. Previously he had used an angular knife instead of Langenbeck's raspator, and the sloughing of the parts was due, he thought, to his taking too thin a portion off. The maxillæ had been brought together in infants in America.

DR. VANDERVEER, U.S.A., questioned if American surgeons did slit up united soft palates. He had never heard of it being done in America. At Boston, Dr. Warren had tried Sir W. Ferguson's operation, and failed. He had also attempted it, and had succeeded in uniting the soft palate, but not the hard. He had come to England especially to gain information on the subject.

MR. OAKLEY COLES referred the last speaker to the "Transactions of the Odontological Society."

Dr. CROMBIE recommended the galvanic canterly for dividing the bone, as causing less hæmorrhage than the drill.

Dr. DRYSDALE thought that obturators were very suitable for improving the voice, and quoted an instance of an actor in Paris remarkable for his good articulation, who, nevertheless, had perforation of the hard palate, cured to some extent by an obturator.

Mr. ACTON used to deplore that syphilitic cases were not operated on in this way, but deplored it less now, as he noticed in the present case the voice was far from perfect.

Mr. MASON explained that his reasons for adopting the perforating method was that both Dieffenbach's and Langenbeck's led to extensive exfoliation of the bone.

Mr. GANT was pleased at the thorough discussion that had taken place. After tracing the history of the operation, he remarked that one difficulty was the complete closure of the cleft where the soft and hard palate met. In one case he had accomplished this by the use of heated wire.

Mr. ROSE briefly replied, and the meeting adjourned.

WEDNESDAY, DECEMBER 23, 1874.

### METROPOLITAN HOSPITAL SUNDAY FUND.

THE debate which took place last week at the Mansion House has shown clearly that the institution of a special public body to administer public charities in London is likely to prove a most important means of moralising the managers of our hospitals. Who of us is there that has not often suspected that the gravest and most flagrant examples of dishonesty lurked among the irresponsible committees and managers of many of these vast institutions? Accounts unaudited, or audited only by some person totally unacquainted with business affairs, drug bills of enormous length passed with haste and unexamined, because some of the officials were in collusion with each other, salaries of said officials equalling in extent, or nearly equalling, the amount expended on the sick poor; whilst the only honest and well-educated class of employed men in the establishment—the medical honorary staff—is snubbed and treated with impertinence and vulgar arrogance by a host of shopkeepers and purse-proud speculators, who employ the hospital as a means of advertising themselves on their career towards civic dignities or positions in the vestry. Such are but a few of the myriad of evils arising from the system of uninvestigated public charities in London.

In Paris, where there is a central body, or *Assistance*

*Publique*, which alone is allowed to manage the public hospitals and funds left by kind-hearted persons to aid their poorer neighbours in distress, all medical men know how much preferable is the position of those who make hospital appointments the road to honour and livelihood. In the first place, in Paris all the posts of distinction in hospitals are obtained by open competition among all qualified members of the profession, and these being obtained, the physicians and surgeons of Parisian hospitals are naturally entrusted with the sole and supreme authority in their own department. In London, on the contrary, it is notorious that the secretaries and treasurers of many of the most important medical charities are enabled, by the power they irresponsibly wield, to make even the most eminent men in our noble calling perform acts which are not in consonance with the position which the medical man ought to hold as the only responsible person in matters relating to the care of the lives of the poor. Who has not heard of the officials of this or that hospital, and their assumption of unlimited authority over the eminent men who have, notwithstanding the contemptible system which regulates appointments in London, from time to time appeared among the professional staffs of such hospitals?

In the smaller and less-known charities, which seem in many cases to exist merely for the benefit of the secretary and his family, an amount of indignity may be attempted to be put on such members of any medical staff as do not agree with everything done by the committee or its officials, or fail to believe their unprofessional judgment sufficient to provide unassisted for the wants of the unfortunate and the diseased, as might well sicken persons less patient and self-denying than medical men are with all kinds of medical charities whatsoever. Were it not, indeed, for the absorbing interest of all connected with the health of the race, we cannot help thinking that the medical men of London would long ago have combined resolutely to have forced the hospitals of London to be managed in such a way as to prove of service both to the patients of the metropolis and also to themselves.

The said meeting of the Council of the Hospital Sunday Fund was its first meeting since June, when the collection was made, and when the sum obtained from all sources was found to amount to nearly £30,000. At the meeting of last week the medical journals of London were well represented in the persons of Mr. Brudenell Carter, Dr. Glover, and other able gentlemen. Mr. Carter proposed that a few gentlemen who represented large and small hospitals and dispensaries should be joined to the Distribution Committee, in order to try to find out the best principles on which any future distribution of funds should be made. There have hitherto been nine gentlemen on the Distribution Committee, and, on the whole, they have done their work most justly and well. Still, there is no doubt that the public and the profession would be glad to have it distinctly stated on what grounds some hospitals have received much more substantial grants from the Fund than others. And here we would mention the only fault we have to find against the action of the honorary secretaries—viz., that they do not call the Council together to receive the reports of the Distribution Committee and of the General Purposes Committee before

the awards are made known to the general public and the final report printed for distribution. This is to our minds an error of judgment which it were well to remedy on future occasions.

The treatment of provident dispensaries by the Distribution Committee has not given satisfaction to the mass of London practitioners, who are looking to these new institutions for some relief in the dead lock which has recently taken place in the working of charitable institutions, affecting as these do so much the welfare of the profession. If there be one point on which general practitioners are more agreed than on another, it is with respect to the value of provident dispensaries. The presence of medical men on the Distribution Committee will be of great assistance to the principle of self-help. The public-spirited speeches made by Sir Sydney Waterlow and by Sir Charles Trevelyan give us all steady hope that there will be in future eyes watching the holes and corners of our hospitals, which have hitherto been dwelling in the dim and unwholesome twilight of obscurity. Chairmen of committees must now be on their guard to see that accounts are made up in a fair and honourable way, and that the money given by good men and women for the care of the sick and indigent is not turned over to some political friend, who, as the wages of *employés* of the hospital, receives the reward due to faithful service in election days.

Medical men will now have a court of appeal from the impertinent assumptions of non-professional men who are so fond of employing doctors for nothing, as Sydney Smith remarked, to relieve them from their duty in showing kindness and thoughtfulness towards their servants and dependents. And it is to be hoped that this new Hospital Sunday Committee may not be content only with administering charity to the poor of London, but that it may, perchance, think that over-much gratis doctoring is likely to be of scanty service in the long run to the poor of London themselves. As it is at present, it is notorious that the gratis system of hospital appointments tends to keep out of many of our hospitals those who would be most useful to the poor, because they are compelled to work in order to live. We do not say that much good work is not done by non-paid men—perhaps the best of all work must ever be unpaid—but there is a tendency in human nature for persons who are not paid to feel less responsibility than those who take a retaining fee.

#### HAMPSTEAD AT BAY.

THE people at Hampstead, that pleasant and salubrious mountain-land of the cockney, are at present in a state of mind almost bordering on frenzy at the prospect of another hospital being added to the list of those already located in their little town during the past few years. A consumption hospital—the North London Consumption Hospital—was the first, we believe, to obtain a local habitation in the place, and we hear that its directors have quite recently bought a very charming piece of ground, with a house on it, for thirty-six beds, which they contemplate making into a larger hospital as years run by. The worthy magistrates of Hampstead, fired by a noble ambition to keep up the rents in their salubrious district, have, it

seems, been at continued warfare with the Committee of the said North London Consumption Hospital with respect to the dangerous class of cases which necessarily too often occupy the wards of the hospital; and their influence has been powerful enough, it is said, to compel the Committee to have a sort of tacit law that no poor consumptive patient is, if possible, to be allowed to die in its hospital, thereby swelling the bills of mortality, and lowering the prestige of the breezy northern suburb, and, as before hinted, the rents of lodging-houses, &c. To die in Hampstead is a kind of crime, it would seem, just as it is in some fashionable watering-places abroad, where we hear of all funerals being compelled to be carried out at night, so as not to interfere with the gaiety and splendour of fashion during the season.

Alas! Hampstead has recently been insulted by having a hospital for small-pox thrust upon her sunny slopes, and, horror upon horror! she is now menaced by the permanent infliction of a fever hospital, similar to that in Liverpool Road, Islington, and in other less sacred spots of our huge metropolis.

Decidedly it is time for the men of Hampstead to speak out; and accordingly there are rumours of meetings and of deputations of enraged householders to protest against the desecration of the holy hill. The brave inhabitants are determined to spare no pains to keep fever, consumptive, and small-pox patients as much as possible in the unhealthy parts of London, in order to save themselves from an enhanced death-rate.

Now, all of this is, we must plainly say, very selfish and contemptible in our friends and citizens of Hampstead. If any one of them with a little money in his pocket were to be seized with threatenings of consumption, would he not gladly be removed to purer air and healthier localities than those where the disease was contracted? And, if Hampstead be, as many think of it, the natural sanitarium of London, is it not most unfair to wish to keep poor weary London consumptives, or fever patients, in bad air and crowded localities when a short journey will bring them into such fresh breezes as blow about the little town? The death-rate of Hampstead can easily be kept separate from that enhanced by the deaths occurring in any hospitals that may be erected there, and thus the town need not lose its good character, however many hospitals be brought thither.

As to a permanent fever hospital being a calamity to Hampstead, if erected there, one has only to remember that the inhabitants of Islington once on a time entertained this groundless fear—a fear which has been entirely dissipated by experience, since such a thing as a case of fever spreading to any of the houses adjoining the hospital in the Liverpool Road is quite unheard of. The houses opposite the hospital, and around it, separated as some of these latter are merely by a strip of garden, have never been known to have caught the slightest infection from any hospital patient; and this tale holds good for all other fever hospitals, if managed with the commonest attention to hygiene.

Let us, then, hope that the citizens of Hampstead may pluck up heart of grace, and think that they inhabit a piece of the earth which has not been made only for themselves and their families, but which, from its vicinity to our huge

and teeming metropolis, is the natural sanitarium of all of us when sick and unable to be removed to a distance. To live for others is a Christian duty, and must not be forgotten even in the wilds of Hampstead Heath. England expects Hampstead, as well as every man and woman, to do its duty to the poor and suffering.

## THE ACTION OF DRUGS.

### VII.

THE next part of the labours of the Edinburgh Committee enters upon newer ground, and is deserving of careful attention. Professor Hughes Bennett proceeds to record the various experiments undertaken by the Committee to ascertain the antagonism between tea, coffee, cocaine, theine, caffeine, and guaranine, on the one hand, and morphia on the other, and this investigation was divided into three parts: 1. An inquiry into the physiological properties of cocaine, the active principle of the plant known as *Erythroxylin coca*, of theine, of caffeine, and of guaranine; 2. An inquiry to ascertain whether or not the active principles theine, caffeine, and guaranine, act as antagonists to fatal doses of morphia or opium; and 3. An inquiry to ascertain whether or not strong infusion of tea or decoction of coffee, when introduced into the stomach, act as antagonists to fatal doses of morphia or opium.

As but little, if anything, is known of the physiological action of these substances, the Committee wisely set to work to increase their knowledge in that direction first, and have placed on record a series of highly interesting and highly important experiments which will serve as a guide both to future experimenters, and also be of practical value to the scientific therapist, who must often wish that he had as complete a record of the physiological action of drugs in daily use, so that he might be able to redeem his art from the stigma of empiricism. If, instead of seeking fresh woods and pastures new for remedies to combat the ills that flesh is heir to, we were to institute a series of experiments to ascertain the physiological properties of those we have now in use, we might then hope to arrive in time at some definite and satisfactory mode of treating disease, and not be obliged to fly to every fresh medicine which, patronised by some fashionable physician, is ushered into the medical world as a panacea for all forms of disease, and, after having been tried and found wanting, is rejected and forgotten, only to come up again as a novelty some hundred years hence. Instead of being content with the statement of (probably) some empiric that such a drug is a powerful "diuretic," "narcotic," or "purgative," why not let some authorised person or committee be deputed to ascertain its full physiological properties before including it amongst our remedial agents and giving it a place in our Pharmacopœia? Thus we should know what each drug could and what it could not do, and blind faith would then give place to knowledge. But, after this digression, let us return to the experiments now under consideration.

The general results from thirty experiments on frogs, mice, and rabbits, as to the physiological action of cocaine, were as follows:—

1. The physiological actions of erythroxylin coca are due to its proximate principle, cocaine.

2. Cocaine is a powerful poison, inducing a series of symptoms affecting the nervous, respiratory, circulatory,

and vaso-motor systems, which terminate, if the dose be large enough, in death.

3. Cocaine, in small doses not ending fatally, produces—1, cerebral excitement, not succeeded by coma; and 2, partial loss of sensibility.

4. In large doses, cocaine produces—1, cerebral excitement; 2, complete paralysis of sensibility; 3, tetanic spasms and convulsions; and 4, death.

5. Cocaine paralyses the entire posterior columns of the spinal cord, also the entire system of peripheral sensory nerves; but the anterior columns of the cord and the peripheral motor nerves are not paralysed.

6. Cocaine frequently produces convulsions of a clonic character; but occasionally it causes tetanic spasms, which latter are sometimes so severe as to produce opisthotonos. There is, at first sight, a resemblance between these spasms and those following the administration of strychnine; but, in the case of strychnine, the action of the poison is limited to the spinal cord, the reflex function of which is so much excited that the slightest touch from without causes powerful spasms. A poisonous dose of cocaine, on the other hand, paralyses the sensory nerves, so that external irritations do not affect the cord; but, notwithstanding, there are strong spontaneous spasms, which are probably caused by the reflex action of the drug on the cord itself, and which spasms are not to be considered as reflex in their nature.

7. Cocaine does not produce muscular paralysis.

8. Cocaine at first increases, then impedes, and lastly stops, respiration.

9. Cocaine at first increases, and finally diminishes, both the force and frequency of the heart's contractions.

10. Cocaine produces at first contraction, afterwards dilatation or paralysis, of the capillaries and small blood-vessels, with stasis of the blood, indicating first irritation and subsequent paralysis of the vaso-motor nerves. This action of cocaine upon the capillary blood-vessels, now described for the first time, is of great interest, as it simulates the action of the drug in this respect to that of nitrite of amyl described by Dr. Richardson.

The experiments contained in Table 35 show a very small quantity of cocaine is sufficient to kill a mouse as compared with a frog, for 1-32nd of a grain proved fatal to a mouse, while a frog recovered from 1-16th of a grain (Experiments 384, 386, 387), but succumbed to 1-12th (Experiment 388); but there would seem to be difference in tolerance of drugs amongst frogs as well as men, for the frogs used in the Experiments 395-396 died after 1-32nd of a grain; but why, we are not told.

The rabbit used in Experiment 394 took in all 12 grains in divided doses, but recovered, although the physiological effects were pretty well marked, for, from first dose there was congestion of ears; from second dose, slight cerebral excitement; from third dose, great irritability, no loss of sensibility; from fourth dose, congestion of ears increased; from fifth dose, depression, staggering gait. Numbers of respirations and pulsations of the heart—1st increased, and 2nd diminished. Temperature: 1st diminished, and 2nd increased.

The Committee next investigated the physiological properties of extract of coca, and found that a mouse succumbed to 2 grains; a frog recovered from 2½ grains, but was killed by 3 grains; while a rabbit took 12 grains without any apparent effect. In Tables 37 to 49 the effect of cocaine, caffeine, and theine on the respiration, cardiac pulsations, and temperature are recorded, and we find that they bear out the conclusions we have already quoted; but there is one point not included in those conclusions to which we wish to draw attention—viz., the effect produced

upon the temperature by these drugs. In Table 43, after the injection of theine, the temperature in a rabbit rose from 33.2 C. to 35.5 C., and gradually fell to 33.9 C. (the normal temperature is stated to be 33.8 C.), and in Experiment 394 we are told the temperature is first diminished and then increased after the injection of cocaine. In Table 46 we see that, after the injection of caffeine, the temperature rose to 36.6 C.; and (Table 49) after the injection of guaranine the temperature rose to 35 C. It is thus evident that theine, caffeine, and guaranine tend to raise the temperature above the normal, and it is stated that cocaine first diminishes but then raises the temperature; theine and guaranine seem also at first to reduce the temperature. The question we naturally ask is, Is this a property peculiar to these drugs, or is it a property common to most drugs when introduced into the healthy system? For we find it stated in Messrs. Burness and Mavor's (a) work that they experimented with various drugs, and observed that in the horse tincture of *datura tatula* raised the temperature from 99 4-5ths F. to 100 3-5ths F.; acetate of morphia in 4 grain doses raised the temperature from 99 4-5ths F. to 100 3-5ths F., and then it fell to 100 2-5ths F., and remained thus for 24 hours. One-quarter of a grain of atropia raised the temperature from 99 3-5ths F. to 100 4-5ths F., and did not fall to 99 3-5ths F. till the third day; one drachm of opium followed by a quarter of a grain of atropia raised the temperature to 105° F.; whilst one drachm of bichromate of potash raised the temperature from 100 1-5th F. to 106 1-5th F. in 4 hours.

These experimenters conclude, that various non-nutritious agents introduced into the system in health, by producing deranged function, tend to raise temperature; they, however, state there are certain drugs which lower temperature, such as chloral, &c.

We call attention to the above experiments, as this point is worthy of notice by those who are investigating the effects of drugs, and have thus opportunities of noting the effects produced upon temperature.

From their experiments with theine, caffeine, and guaranine, the Committee conclude that their physiological effects are identical with cocaine. They, however, conducted a series of experiments with theine on frogs, rabbits, and cats, which are also fully reported, and to which we direct our readers' attention, only quoting the concluding remarks of the report, which are as follows:—

From these experiments, and those in the Tables 50, 51, and 52, the general conclusion may be drawn, that, as cocaine, theine, caffeine, and guaranine chemically resemble one another, so do their physiological actions seem precisely similar.

Numerous observations made on larger animals (cats and rabbits) with the three last substances demonstrated the following facts, in addition to those already determined with cocaine:—

1. These three alkaloids—theine, caffeine, and guaranine—produce an increase of the salivary secretion.
2. They produce a peculiar form of tenesmus, accompanied by a copious discharge of clear mucus from the bowels.
3. They usually produce contraction of the pupil.
4. They affect the temperature by (1) slightly lowering and (2) increasing it.

Although we have not been able to demonstrate that

these four properties also belong to cocaine, we have every reason to believe, judging from their other analogies, that if similar doses of it were given the same results would ensue.

### CONJOINT EXAMINATION AND ITS PROSPECTS.

ALTHOUGH more than six months have elapsed since the proposition for Conjoint Schemes of Examination were prominently before our readers in these columns, the approach of a Parliamentary resurrection once again calls the attention of medical politicians to the subject, and re-animates medical reformers in the pursuit of that hoped-for condition of affairs which seemed to have eluded their grasp last May.

Those who have not kept the matter in view may need to be reminded that at the date of our last report the Apothecaries' Company and the University of London had obtained from Parliament legislative authority to co-operate with the Colleges in the Scheme for Conjoint Examination for England—the "Reference Committee" had reported "gushingly" in favour of the proposal—most details of arrangement had been decided upon—nothing appeared wanting but to recite the prologue and send up the curtain; and we were actually promised the disclosure of the first scene within a month or six weeks.

So much for England. In Scotland, and in the Queen's University of Ireland, the licensing bodies were terror-stricken by the prospect of their "craft" of cheap-diploma vending being "set at nought." All was confusion in the northern camp, and nothing was decided upon, except the very hearty mutual understanding amongst the corporations that anything in the way of improvement in examination and in the status of the profession should be resisted shoulder to shoulder, and by every tactical method which diplomacy might suggest. Delays, special pleading, open antagonism, legal ruses, all or any means were to be used to keep alive for another year or two the money-making Scotch trade in cheap and easy diplomas.

In Ireland the effort at a self-reform of the corporations looked almost as promising as in England. The University of Dublin, the two Colleges, and the Apothecaries' Hall had entered into a practicable and mutually beneficial compact, and all was ready for a matter-of-course application to Parliament for legal authority for their acts. The examiners were already appointed, the fees fixed, and even the hours of examination anticipated, and we were promised a complete system of unified examination in a few months.

Those who read the foregoing recapitulation of the expectations of medical reform a few months since will hardly realise that the present state of affairs can have been the outcome of such loud-spoken promises; nor will they entertain a very exalted opinion of the sincerity of conviction of those who spoke so trumpet-tongued in favour of Conjoint Examination as recently as last May.

In Scotland, indeed, and in the Irish Queen's University, community of interest has ensured steadfastness of purpose, and no one has flinched from the homely determination to defend, at all hazards, the common pocket interest. Indeed, it may be safely predicated by anyone who studies

(a) "Specific Action of Drugs," p. 28.

the Scotch character, or who knows how foreign to enlarged ideas of medical reform is the cheap diploma line of business, that this unanimity of opposition will continue, and that if Conjoint Examinations are to be the qualifying system of the future, they must be so constituted in spite of the violent resistance of the bodies which exist by the abuses of the unreformed condition of affairs. The cheap diploma grantors indeed openly plead that, as there must always be "dirty butter for servants"—partly educated and inferior classed practitioners for beggarly districts—they ought to be allowed to supply the market with this class of goods, and that it would be a universal evil to withhold the services of semi-competent medical men from that class of the public who cannot pay for fully educated advisers.

In England the obstruction to Conjoint Examination, if less sincere, has become somewhat influential. The Council of the London College of Surgeons, which had expressed unbounded rapture at the prospect of self-reform, has cooled upon its intention. It is not the way of councils to express plainly their vacillations of opinion, but they have an equally efficient, and perhaps less humiliating way of effecting the same object. The Council of the London College suddenly discovered that there were legal difficulties in the way of a fusion—impediments of which for two years they had taken no heed, but which were at the right moment brought out and erected into a barricade to bar the way of advancing reformers. This policy once decided on, there was the usual references to a committee, and reports back to council, and consultations with law officers, and so effectually has the obstruction been managed that the question is now where it was last February, and we hear that another enabling act is to be passed in the coming session of Parliament to clear the way.

In Ireland the case is still less satisfactory, and still less creditable to those who carried the banner of Conjoint Examination. As we have said, the arrangements had reached their final stage when it became evident that the question of a reduction in the number of lectures and fees required from the student should be dealt with. Everyone was aware that a curtailment of compulsory certificates, and consequently of professional fees, was absolutely inevitable; but it seemed that the lecturing and grinding interest had but newly awakened to this necessity. Accordingly, the trumpet was sounded to arms by some of those who had been consentients to the previous arrangements. Secret meetings were held, and secret pledges given, and a *coup* was thereby effected at the election of Council for the College of Surgeons, which placed upon the administration several avowed exponents of the anti-reform interest. One of the most outspoken advocates of improvement lost his seat, and the remaining band, although numerically in a great majority on the Council, were so scared at the vigour of the "grinding" onset that their war cry has since been unheard.

This narrative is an instructive one, and one which goes far to justify the policy of the ultra-radical party, whose platform it is to reform the profession over the bodies of the corporate bodies.

We entertained, we confess, a confidence which we hope will not turn out to have been misplaced, that the men who had staked their names and their characters upon their

sincerity in the cause of Conjoint Examination valued their convictions more than their places, and would be ready to sustain their opinions in defiance of all the individual interests which must necessarily intervene in the settlement of such a matter.

It would ill-become such men to accept as inevitable a corrupt and moribund system because it is sustained by a clamorous crowd of interested belligerents. We venture to remind the advocates of corporate self-reform that the hour has come for them to renew their efforts, and that, if they are discouraged in doing so, they place a weapon in the hands of the sweeping revolutionists of the medical qualifying system which they will not be slow to use.

## Notes on Current Topics.

### Chinese Opium-eaters.

A GREAT increase is reported of the quantity of opium imported into China, and the consumption of this dangerous poison seems all but universal in China. It appears that many persons are not apparently much damaged in health from the use of opium. The authorities occasionally issue edicts forbidding the use of opium. Tobacco and opium smoking are wonderful facts in an age which promises to be so eager in its cultivation of public hygiene.

### Medical Fees.

A CASE came recently before the Court at Brighton, when a practitioner of that city brought an action against a certain Mr. Reynolds to recover fees, charged at the rate of seven shillings a visit. The judge said that if the plaintiff were a physician, and practising as such, he was entitled to be paid according to the remuneration of physicians. A verdict was given for the plaintiff.

### The Navy Blue-Book.

MEDICAL officers of the Navy, says Dr. Mackay, continue to praise the Contagious Diseases Acts. At the Cape of Good Hope and at Bombay, where the Acts have been repealed, the spread of disease has been marked; and this holds good for Port Royal, Jamaica, where the Acts have been suspended. At Hong Kong it is said that disease has been reduced to a minimum.

An epidemic of yellow fever occurred at Port Royal, Jamaica, in 1873. Of 43 cases of this disease, 27 proved fatal. Yellow fever also prevailed at Rio de Janeiro. Dysentery prevailed in the Pacific squadron, as also off the African Coast. The ratio of mortality in the whole navy was only 6 per 1000, and in 1872 it was 5.6 per 1000.

### Malignant Tumour of the Cerebellum.

DR. MORGAN, of Manchester, showed at the Manchester Medical Society, in October last, a malignant tumour of the cerebellum. The patient, æt. 45, was admitted into hospital on February 16, and the chief symptoms were dizziness, headache, vomiting, and constipation, sometimes for a week at a time. There was double optic neuritis, and the patient died comatose. A tumour the size of a pigeon's egg was found involving the left cerebellar lobe, en-

croaching on the corresponding side of the medulla, so as almost to obliterate it, and extending into the fourth ventricle. The tumour was contained in a distinct sac, which had a delicate lining membrane, and out of which a quantity of apparently puriform fluid escaped. This, when examined microscopically, consisted of granules and cells of various sizes, with granular contents. The harder portions of the tumour were made up of cells of rounded shape, and containing one or more nucleolated nuclei. These cells were separated by fine intercellular substance, and closely packed in spaces formed by the blood-vessels.

### Poisoned by Cigar-smoking.

In the *Journal des Connaissances Médicales* of MM. Caffé and Cornil we read the following: M. Prof. Chevallier reports in his journal the case of a young man who made a wager that he could smoke twelve cigars, and forthwith went to work to do so. At the eighth cigar he began to experience suffering, at the ninth chills and flushes supervened, which symptoms became worse at the tenth cigar. He, however, refused to stop, and went homeward. On arriving at home he had pains in the bowels, and vomiting, and died in the night. He is said to have suffered from cardio hypertrophy.

### Treatment of Diabetes.

DR. GEORGE BALFOUR, of Edinburgh, gives as diet in diabetes skim milk, meat, and large doses of lactic acid, three to nine drachms daily. In seven cases two were completely cured, two died of phthisis, two went away, and in the last case death occurred in two years, after great benefit for a time. Drs. Ebstein and Müller, of Breslau, recommend carbolic acid in the second stage of diabetes, as much as six grains a day; but Balfour has found this not to be of much use.

### The Proposed Charter of the Irish College of Physicians.

At a meeting of the College held last week, a reply drawn up by a committee appointed to answer the dissent from the proposed supplemental charter was considered. It was resolved to forward the reply to Sir Michael Hicks Beach. The *Freeman's Journal* has heard that at a meeting of the College on the 14th inst. a resolution was passed censuring the conduct of some of the Fellows who communicated their dissent from the proposed charter directly to the Government. As this vote of censure was irregular for want of due notice to the College and to the Fellows implicated, a formal notice of motion to censure the supposed offending Fellows was given, and will be discussed by the College at its January meeting.

### The late Dr. William Hargrave.

At the last meeting of the Governors of the City of Dublin Hospital the following resolution was passed unanimously:—"That this Board desire to express their deep condolence with the family of the late Dr. Hargrave upon the decease of one who was for thirty-six years a valuable and honoured member of this Board, most constant in his attendance, and ever zealous for the welfare and prosperity of the City of Dublin Hospital."

### Adulteration Defined.

It seems to have defied the ingenuity of legislators and bill-drawers to fix an intelligible definition for adulteration. Is it "adulteration" to sophisticate a product with an innocuous article? or with an addition which is admittedly an improvement? or to add minute quantities of anything for the purpose of flavouring? or to abstract from an article any of its constituents, as in the case of skim milk.

The Society of Analysts have had constant experience of the failure of prosecutions resulting from the ambiguity of the words of the Act, and they have consequently set themselves to work to frame a definition. They have, after much anxious debate, resolved—

"That the following having been unanimously agreed to by the Committee appointed for the purpose, is considered as a fair definition of an adulterated article, and they recommend it to the Council of the Society as one which may advantageously be adopted as a guide."

### PROPOSED DEFINITION.

An article shall be deemed to be adulterated:—

#### A. In the case of food or drink:—

1. If it contain any ingredient which may render such article injurious to the health of a consumer.
2. If it contain any substance that sensibly increases its weight, bulk, or strength, unless the presence of such substance be due to circumstances necessarily appertaining to its collection or manufacture, or be necessary for its preservation, or be acknowledged at the time of sale.
3. If any important constituent has been wholly or in part abstracted, without acknowledgment being made at the time of sale.
4. If it be a colourable imitation of, or be sold under the name of, another article.

#### B. In the case of drugs:—

1. If when retailed for medicinal purposes under a name recognised in the British Pharmacopœia, it be not equal in strength and purity to the standard laid down in that work.
2. If when sold under a name not recognised in the British Pharmacopœia, it differs materially from the professed standard.

Proposed standards or limits for milk, skim-milk, butter, tea, cocoa, and vinegar were then given.

It was stated by speakers on the occasion that, although fraud was in most cases the obvious intention of the vendors of adulterated articles, still the introduction of the word "fraudulent" into the Act had rendered nugatory very many prosecutions under it, because neither juries nor magistrates were willing to find a trader guilty of intentional frauds. We all know what we mean by an adulteration, which, for our own purposes, we may define to be "when a rogue adds to or takes from the article which he sells in order to cheat his customer," but, unfortunately, these sort of common sense definitions won't do for legal purposes.

Apocryph of this subject, we note that at Bradford, last week, several persons were summoned for selling adulterated pepper. In none of the cases were the articles used for the adulteration injurious to health, but the adulterations varied from 20 to 30 and from 40 to 75 per cent. The principal commodity used to mix with the pepper was peameal, which may be had at about 1d. per lb.

### Prosecution by the Excise Authorities at Hull.

A PROSECUTION has been instituted by the excise authorities at Hull which involves in principle some of the important interests of the profession.

A chemist was summoned for retailing certain spirits, to wit, spirits contained in a certain compound called "pick-me-up," without his having a licence to sell excisable liquors. A bottle of it was purchased by the excise officer, and it was sent for analysis to London. The mixture was then found to contain 67·7 of proof spirit, and was flavoured with ginger, orange peel, and gentian. In consequence of the amount of proof spirit being found in the mixture, the excise authorities had brought the case into Court. The Crown counsel said that he was told that the gin and bitters sold by the publican did not contain more than 40 per cent. of spirit, and in the event of this being so, the defendant would, he contended, be liable for selling spirit without a licence.

The defence was that the "pick-me-up" was not a beverage, but was a medicinal tincture and similar in taste and quality to the tr. gentian co., and that the chemist was as much entitled to sell it, no matter how much spirit it contained, as to sell any Pharmacopoeial tincture. The case was eventually adjourned, and we shall report the decision of the Bench in our next. Meanwhile, an influential meeting of the chemists and druggists of Hull has been held to take the matter into consideration. The commencement of such a prosecution, without previous notice, was thought to be a harsh and oppressive proceeding, and a resolution was passed "to take such steps in the general interests of the trade as may be deemed necessary in defending the case and obtaining a clear definition of the law upon the subject."

Little as we can sympathise with those who drive a trade in stimulants intended as an habitual remedy for the effects of beastly drunkenness over-night, we cannot see how such a prosecution is tenable at all. It was sworn to and obvious that the "pick-me-up" was nauseous in taste and to be taken only in small quantities, and we cannot conceive how the excise authorities can control that it is anything but a bitter tincture, made up for curative purposes. If the defendant were convicted it would seem to follow logically that no preparation used for restorative or tonic or even sedative purposes, except those formulated in the British Pharmacopoeia, could be legally sold by an unlicensed dealer as long as the proportion of spirit present exceeded the excise standard.

### Labourers' Dwellings in Ireland.

It is not for the information of Irish Poor-law medical officers, but for the perusal of "centres of intelligence," *vulgo*, Poor-law guardians, that we quote the following official reports of the registrars of Irish dispensary districts upon their sanitary condition. The excerpts are only a few of the most moving, but if we should undertake to reprint all the denunciations of the sanitation of Ireland we should be prepared to reproduce the entire report. The Registrar of Castlegregory District, Co. Cork, says:—

Fever was prevalent, only one case terminating fatally. She was the wife of one of the most respectable and opulent

farmers in the district; notwithstanding which, when I first visited her in illness, I found the house so filthy and so full of stench from numerous pigs kept inside, that it would not have been wonderful if every human inmate had died. Her father-in-law, sister-in-law, and a third person who frequently visited the house, had, immediately before her illness been suffering from large purulent deposits in various parts of their bodies.

*Goleen, Co. Cork.*—Fever of a low type is now prevalent, and I very much regret to say that I fear my next return of deaths will be considerably over the average. The sanitary state of the district is worse than ever, and shamefully neglected. The universal practice of medical men is, when they go into one of the sick dens to visit fever or other patients, to have the doors thrown open; but I must have the doors closed, as, bad as is the place inside, the stench from the cesspools is positively intolerable.

*Keadue, Co. Roscommon.*—Scarlatina and whooping-cough have been very prevalent. The sanitary condition of most of the dwellings of the poor in this district is much neglected, cows, pigs, and horses being lodged in the houses, which are in general small, ill-ventilated, dirty, over-crowded, without sewerage, and having cesspools before the door, and the people themselves are perfectly ignorant of the use of disinfectants, and careless in cases of infectious disease.

*Scrubby, Co. Longford.*—Deaths this quarter are above the average. I fear the scarlatina was greatly spread by want of proper sanitary arrangements in the district. In some of the houses I have seen a pig-house built in a corner of the kitchen or principal apartment of the house, and a patient in scarlatina in a bed beside it, a goat tied in another corner, and a cesspool in front of the house; indeed, in a great number of houses in the remote parts of the district, it is a common thing to see the family living in the same house with the cattle.

*Ballynacarrigy, Co. Westmeath.*—Deaths over the average. The sanitary condition of the dwellings of the small farmer and labouring classes is simply shocking; stagnant cesspools, uncleaned pig and fowl houses, and dirt in every form abound on all sides and form a ready *nidus* for the production and propagation of every zymotic disorder in its most aggravated type.

These are the sort of localities in which the guardians think that 6½d. a day is plentiful payment for the medical officer of health, and in which the dispensary doctor is supposed to earn his 3s. 6d. a week by acting as sanitary detective amongst his own patients.

### University of Edinburgh—Additional Examiners in Medicine.

NOTICE has been given that the Court of the University of Edinburgh will proceed to the appointment of additional examiners in medicine under the system introduced by an alteration of ordinances last year.

The divisions and subjects of the examinations are:—

1. Chemistry, botany, and natural history; 2. Anatomy, institutes of medicine, materia medica, and pathology; 3. Surgery, practice of medicine, midwifery, and medical jurisprudence; and, 4. Clinical medicine and clinical surgery.

Persons may be appointed to examine in two of the above subjects, but not more, and not to more than one in the same division.

The fee is £50 for each subject of examination.

The appointments are annual, but persons may be re-appointed annually for five consecutive years.

DR. JOHN HOMES, of Brighton, has been elected on the School Board of that city. It is evidently of the greatest importance that many medical men should become directors of the new educational establishments springing up around us.

### The Dangers of Anæsthetics.

A CASE of death from bichloride of methylene is reported from the Moorfields Ophthalmic Hospital, and one from chloroform in the Royal Free Hospital. If the published statements are to be depended on, the cases were in all respects suitable for their administration, and the cause of death was inexplicable—syncope—and, if this be so, the dangers of these anæsthetics are all the more serious. It would be more encouraging to patients and administrators if there had been some obvious bungle which could, in future, be avoided. The ether revival seems to have died out; not, we imagine, in consequence of the short-comings of that agent, but because it is not found "to pay" to take trouble about the saving of an occasional life.

### The Effect of the Scarlatina Epidemic in Ireland upon the Death-rate.

It appears from the last official reports that the deaths registered in Ireland during the quarter ended 30th September last, amounted to an annual ratio of 14·8 per 1,000 of the population, which rate is 1 per 1,000 over the average for the third quarter of the preceding five years.

The deaths registered in Leinster during the quarter afford an annual rate of 17·6 in every 1,000, in Munster 13·9, in Ulster 14·9, and in Connaught 11·7 per 1,000.

The death-rate was highest in the following counties:—Dublin 23·1 per 1,000, Antrim 19·0, Westmeath 18·7, Carlow 18·1, Armagh 16·3, and Longford 16·0. The registered mortality was lowest in Leitrim and Sligo, in each of which the rate represented was 10·6 per 1,000; Mayo, in which it was 11·4, Kerry and Roscommon each 11·9, and Cavan 12·0 per 1,000.

The number of deaths in Ireland is 365 in excess of the number during the corresponding period of last year. The Registrar-General's remarks that the sanitary condition of the country is in a very unsatisfactory state, is fully evidenced by the fact of the increased mortality having resulted from seven of the principal zymotic diseases, the deaths from which exceeded by 682 those registered in the corresponding quarter of 1873, and by 172 those in the second quarter of the present year.

Scarlet fever, which has been epidemic for more than twelve months, instead of manifesting any symptoms of abatement, continues its fatal progress with increased malignity. The deaths from scarlet fever registered during the past quarter numbered 976, showing an increased mortality of 245 as compared with the preceding quarter, and of 568 as compared with the corresponding quarter of last year. The disease prevailed chiefly in the provinces of Leinster and Ulster; in the former province the deaths from scarlet fever amounted to 460, and in the latter to 392; whereas in Munster and Connaught only 64 and 60 deaths were respectively the result of this disease. Some of those attacked by scarlet fever succumbed to the disease within a few hours; in a few instances two, three, and four members of the same family were cut off.

### Malta and its Sanitary State.

IN 1871 the population of Malta was 123,373 to ninety-five square miles of territory. The average rate of mortality was 28 per 1,000 for the last ten years. Lately it

has been very healthy, and had a death-rate of only 22·4 in 1873. There is a good deal of poverty in the island, and there is a deficiency of pure water. Overcrowding in its worst form is the usual concomitant of poverty and over-population. Every one says the same now-a-days. But how to remedy poverty and over-population?

### Dr. Parkes Report on Hygiene for 1872.

DR. PARKES, of Netley, in his Report in the Annual Army Medical-Blue-Book, dwells on the additional evidence given of late to show how typhoid fever is occasionally introduced by the medium of milk, and also by clothes soiled by discharges from patients, and hints that other undetected methods for the entrance of the poison may be discovered. This disease has so long an incubation period, about thirty days in some cases, that it is difficult to remember how it arose in many cases.

### Deaths from Methylene and Chloroform.

WE notice the record of no less than three deaths from anæsthetics in journals before us this week. A death from the inhalation of methylene occurred a few days ago at the Royal London Ophthalmic Hospital in a young woman, aged 25, affected with caries of bone near the lachrymal sac. Mr. Buller, whose experience is great, administered the anæsthetic bichloride of methylene by means of a perforated leather inhaler covered with flannel. Three drachms were inhaled, and in two minutes the breathing became stertorous. After the operation, the pulse at the wrist suddenly failed, and then the respiration ceased. The tongue was dragged forward, and Sylvester's method of artificial respiration was made use of for forty minutes, but the patient was dead.

### Typhoid Fever at Oxford.

THE death of a son of Mr. Samuel Laing, the great financier, of typhoid fever contracted at Oxford, will, no doubt, call attention again to the causes of this mysterious disease. It seems that the water supply and drainage of Oxford are both most faulty.

OUR readers will admit that we have done our best to get occasionally a little fun out of that lugubrious subject, the Irish poor-law, and we must confess that our success has been usually rather indifferent.

Our most jocose efforts have been reduced to ignominious eclipse in the last week by a gentleman who, as far as we know his utterances, is not commonly charged with special wit—we mean Mr. Byrne, the gentleman who assumes the dictatorship of the sanitary organisation of Dublin, and especially of the North Union. As the mighty Dan O'Connell left behind him a legacy of soubriquets which have stuck to their owners like a "mother's mark," and have left in our memory the names of "Vinegar" Smith, "Shave Beggar" Morpeth, and other historic personages, so Mr. Byrne has christened the class to which he himself belongs the Irish Board of Guardians with an inefaceable title. At the last meeting of the North Guardians he denounced the Local Government Board for their audacious dictation to the "*centres of intelligence*," the Dublin Guardians.

The epigram is infinitely amusing to those who know all

about the constitution and character of Irish Boards, and lest Mr. Byrne's *bon mot* may be lost to posterity, we suggest that he receive the title of the "Head Centre."

THE Winter Assizes at Lewes will not be held this year, on account of the prevalence of typhoid fever in that town.

TWENTY appointments in the Indian Medical Service will be thrown open in February next. Applications as to the regulations to be made at the India Office.

A NEW provident dispensary, the Kilburn Provident Medical Institution, is to be opened in January, 1875.

A LECTURESHIP in Aural Surgery is talked of as likely to be founded in Glasgow.

IN the county of Banff, in Scotland, about one-fifth of all children born are said to be illegitimate.

THE subject for the Dublin Pathological Society's Gold Medal for the session 1874-75, is "The Human Entozoa."

AT the November examinations of the Pharmaceutical Society of England for the Minor only four out of fifteen were successful.

DR. KEITH, of Edinburgh, is said to have performed ovariectomy now 196 times, with the low mortality of late years of only some 10 per cent. of the cases operated upon.

DR. HENRY BENNET's admirable work entitled "Winter and Spring on the Shores of the Mediterranean," has reached its fifth edition.

SIR GARNET WOLSELEY is of opinion that ere long compulsory military conscription will be the only way of obtaining efficient able-bodied young men.

IN London during the past week, 2,257 births and 2,082 deaths were registered. The births were 62 below, whereas the deaths exceeded by 356 the average numbers in the corresponding week of the last ten years. The annual death-rate from all causes, which in the seven preceding weeks had steadily increased from 20 to 23 per 1,000, was last week equal to 32.

AT a meeting of the Metropolitan Asylums Board, on Saturday, Dr. Brewer in the chair, it was decided that, as the Board had not yet been furnished with the evidence of the necessity of such a large building, and they were about to issue new regulations which it was hoped would lessen the pressure on existing accommodation, they hoped it would prove unnecessary to impose upon metropolitan ratepayers the expenditure involved in the erection of a third asylum. The cost of the proposed building would have exceeded a quarter of a million sterling.

## Foreign Medical Literature.

### IMPROVEMENTS IN THE OPERATION FOR RECTO-VAGINAL FISTULA.

(Translated from *l'Union Méd.* by F. M. LUTHER, M.D.)

AT the close of the last meeting of the Société de Chirurgie, on the 4th of November, M. Tillaux exhibited an instrument fabricated by M. Colin, intended to facilitate the operation for recto-vaginal fistula. Constructed on the principle of Desmarre's forceps for the enucleation of cysts from the eyelids, the instrument is composed of two blades, the one in the form of a ring, the other solid. One is introduced into the rectum, the other into the vagina, and both, when approximated, limit the borders of the fistula, which they allow to be pared without the loss of a drop of blood, and even to have the sutures introduced; for the solid blade is concave, and furnished with a horn-plate, which allows the passage of the needles and thread. One may, in a word, by aid of this instrument, operate upon recto-vaginal fistulas as upon fistulas upon the surface of the body. (a)

On the occasion of the presentation of this instrument by M. Tillaux, M. Démarquay described a new method of operation for recto-vaginal fistula by which he recently obtained excellent results.

M. Démarquay had had occasion to make a series of operations for the cure of recto-vaginal fistulas, and those operations had not been successful. The cause of those failures was due to two things—first, to the accumulation of feces in the large intestine; secondly, to their volume and hardness, and especially to the resistance of the anus when they have to be evacuated. During the efforts of defecation the cicatrix gives way either wholly or partially, and the contents of the bowel pass again into the vagina.

There was, besides, an anatomical condition of failure; it was the tension in the transverse direction of the lower wall of the vagina.

In order to obviate these causes of failure, M. Démarquay adopted the following method with a young woman suffering from a large recto-vaginal fistula, produced by an awkward slip of a cutting instrument in the removal of a uterine polypus.

The operation is divided into two stages.

The first stage consists in cutting through the posterior wall of the rectum, as in the operation for fistula in ano, as far as the coccyx. This, in the first place, relaxes considerably the posterior wall of the vagina; and, secondly, it allows one to operate on the fistula through the rectum, having it completely in view; thirdly, and lastly, it allows the contents of the bowel to escape freely.

The second stage, or the operation properly so called, comprehends several details: first, the edges of the fistula are very freely pared by oblique cuts, as in the operation for vesico-vaginal fistula by the American procedure; secondly, the edges having been freely pared and the flow of blood arrested, M. Démarquay inserts one metallic suture by means of Blandin's curved needles, passing it through the posterior wall of the vagina; he unites the cut surfaces completely by a number of points of suture, of which the threads are knotted (b) in the vagina, as in vesico-vaginal fistula. This is easily done, by reason of the relaxation of the parts consequent on the deep incision of the sphincter. Thanks to this incision, not only do the contents of the large intestine remain but a short time in it, but their evacuation is easily effected, when necessary, by the aid of a gentle laxative.

(a) A ciel ouvert! How? unless the fistula can be everted through the anus?

(b) *Tordus*, twisted. Query—Are those metallic sutures also, or silk threads? The former most likely.

Injectations of cold water are made each morning into the vagina. As there is no tension in the reunited parts, the threads may be left in as long as you like. M. Démarquay proposes to leave them in eight or ten days.

As to the first step of the operation, which consists in incising deeply the margin of the anus, what takes place is this. Little by little the wound cicatrises, and heals perfectly, just as in the operation for fistula in ano.

M. Démarquay's patient got cured of her fistula, and of the preliminary operation. She retained the contents of the bowels as well as if the sphincter had not been cut through.

To those who may consider the preliminary operation proposed by M. Démarquay serious, the author of this method replies that he has often performed it with the view of facilitating operations on the rectum, and that it was unattended by any disagreeable consequences; and then, adds M. Démarquay, is there any infirmity more disgusting for a young woman than a vesico-vaginal fistula and must she not be cured of it at any cost?

## Literature.

### A PRACTICAL TREATISE ON ECZEMA. (a)

WE have read this volume with interest. It relates to a disease of the skin with which most of us are very familiar, and with which our author also seems to have had a large experience. It is rare that any single disease gets an entire volume to itself; but so it is here. Of late, indeed, the attention which has been given to diseases of the skin is something remarkable, and a whole library of works on the subject, we might almost say, has suddenly appeared. We are not sure that the improvement in the practical part of the subject has been at all commensurate with the number of works which have appeared. There has been a great straining to make out new forms of skin disease, and many disputings as to the way skin diseases, eczema amongst the rest, begin. For ourselves, we think great labour and precious time have been lost on these questions, and we could name writers who appear to us to have lost themselves in this kind of pursuit. Our author enters at some length into the question how eczema begins, and states that its various forms may coexist; and in this we quite concur with him. The only distinction which seems to us worthy of notice, is as to whether the disease be acute or chronic; but whether it begin as a vesicle, papule, or pustule, does not, we repeat, appear to us of the slightest moment.

It is not our intention to follow the author through the several chapters, including the symptoms, anatomical lesions, causes, diagnosis, prognosis, and treatment; we must refer our readers to the volume itself for these details: but, whilst reading the work, one or two points of a general character struck us as calling for some notice—thus, at p. 79, the author speaks of the safety of curing eczema, and uses the following expression in reference to this point: "A great deal of nonsense had been written about the danger of suddenly driving in (as the expression goes) a severe or chronic eruption, such as eczema;" and then he goes on to say that "slightly unpleasant effects are occasionally witnessed," so that he blows hot and cold with the same breath. Now, we would warn our readers of the danger of following this advice, even were it possible to follow it to the letter, which we believe it is not; and as to the word "nonsense," we consider it quite out of place. There are the best grounds for knowing that the curing of a skin disease, and especially such a one as

eczema, known to have such a constitutional origin, cannot, nor ought not, to be suddenly cured. That eczema very often relieves the system by its appearance, does not admit a doubt. In the young its sudden suppression has been followed by water on the brain, and here the disease had been confined to the head; and in after-life, when the gouty poison is so often mixed up with the eczema, we have known bad effects at once follow the disappearance of the rash. We have seen pemphigus make its appearance, and confined exclusively to the parts where the eczema had been. Violent cramps, too, are not uncommon under similar circumstances; and we have seen most obstinate cough and some forms of dyspepsia also come on. Everyone, too, must have known bad effects follow the drying up of what seemed at the moment a very trivial discharge. This subject might be pursued very much further, but such is not called for here; and we would only add that, on this point of the drying up or curing such a disease as eczema, too much caution cannot be exercised. How our author cured thousands of cases, as he states, without any unpleasant result, is to us very hard to comprehend. We are sorry too to observe that he sets down to the ignorance of others the difficulty of curing the disease, which, in his hands, of course, was effected at once. This does not seem to us right, and should there be another edition of this work, we suggest its being left out. In the treatment we could have wished the author to have entered farther into details. In a work devoted to one specific disease it would not be too much to have expected this. As an example, we would take iron, which, though mentioned by our author, we consider ought to have been spoken of at much greater length. Unless we are greatly mistaken, this drug is capable of effecting much, not only in the acute, but chronic forms of eczema, and this when used even by itself. Like any other drug, it does not always agree, and cannot be given; but we believe it will agree with the great majority. Experience, however, is required of the dose, special preparation, and mode of administration; and we could have desired that our author had entered into much more detail than he has done. We observe he speaks very favourably of the combination of cod-liver oil with iron, and no doubt it is very effective; but in our experience it is only suited to the young. When the disease occurs in middle life, and more particularly if it be mixed up with gout, the oil and iron mixture does not suit at all. Indeed, this form of eczema, which might be called the gouty, appears to us a much more serious disease than when eczema occurs in earlier life. It is very difficult to make the cure complete, and if done hastily, it is almost sure to be followed by serious results, to which we have already alluded. This phase of the disease has not been taken up specially by our author, and yet, we repeat, it is by much the most severe form of the affection. It can be cured temporarily, but it will recur again and again, and, with our present experience, we doubt whether its complete and permanent eradication be possible.

Our author alludes to the varied forms of eczema, according to the parts of the body affected; but these do not call for any special notice. On the whole, we think more might have been made of the subject, particularly as regards details; in other words, while this work, taken as a whole, may be pronounced a good one, it has not by any means exhausted the subject.

## Correspondence.

### THE COLLEGE OF PHYSICIANS OF IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of last week you comment adversely on the provisions of the Supplemental Charter sought for by the College of Physicians, founding your observation on "The Dissent" put forward by five of the Fellows.

Anyone reading "The Dissent," or your comments, would suppose that the College sought strange and unprecedented powers, as there is nothing to lead him to suppose that the

(a) "A Practical Treatise on Eczema, including its Lichenous and Impetiginous Forms." By Dr. McCall Anderson, Professor of Clinical Medicine in the University of Glasgow; Physician to the Royal Infirmary, to the Dispensary for Skin Diseases, and to the Cutaneous Wards of the Western Infirmary, &c., Glasgow. Third Edition, with Illustrations. London: J. and A. Churchill, 11 New Burlington Street. 1874. Pp. 208.

College merely sought the same powers and rights as are enjoyed by the sister Colleges of London and Edinburgh, in which, moreover, not only is the ballot the means employed in electing Fellows, but in which corporations there exists a small governing body—namely, the Council, which is elected also by ballot. If the right to elect by ballot be not restored to the College, the Fellowship will become a mere purchasable honour, which should be the reward of professional merit. As to the Membership, the College only moved in the matter in the interests of its Licentiates, many of whom from time to time settle in England and Scotland, and are debarred from holding numerous valuable appointments, which are tenable only by Members or Fellows of a College of Physicians; and as the Colleges of Edinburgh and London have a grade of members, it is most unjust that the Irish College should not have the power of placing its Licentiates on a similar footing. That existing Licentiates can receive no injury is evident from a perusal of the enclosed document, which shows that it is intended to preserve in every way their rights. This document, too, is interesting, for it shows that three of the gentlemen who now "dissent" from the proposal—namely, Dr. Haughton, Dr. Cruise, and Dr. Lyons, were members of the committee who, having "carefully considered the whole subject," recommended the College to institute an order of Membership. As nothing has since occurred to alter the case, it is evident that their present "dissent" must be based on other grounds than a desire to advocate the cause of the Licentiates who are not assailed.

I am your obedient servant,

A FELLOW OF THE COLLEGE OF PHYSICIANS.

*Report of the Committee appointed December 6th, 1867, to consider the propriety of instituting an Order of Membership in the College, and, if approved of, the mode of carrying it out.*

Your Committee have to report, after careful consideration of the whole subject, that they are of opinion that it is desirable—

1st. That a new order be instituted in the College, to be called "Members," who shall be admitted (as in the London College of Physicians) either by examination or by election out of the Licentiates.

2nd. That all persons who have been admitted Licentiates of the College before the day of shall be entitled to be admitted members of the College, provided that they have, since their admission as Licentiates, obeyed the bye-laws, and do accept such membership, and engage henceforth to obey the bye-laws of the College.

3rd. That no Member of the College shall compound or dispense medicines for sale.

That with respect to Licentiates, it is desirable—

1st. That the following paragraph in Chap. VI. of the Bye-laws be repealed:

"If the applicant be a member of an Apothecaries' Company, he must surrender his certificate as such, previously to examination; and, if admitted, must not be registered as an apothecary in any part of the United Kingdom."

2nd. That the following words be inserted in the declaration taken by Licentiates, after the word College in line 29, page 17, Chap. VI. of Bye-laws—"keep open shop for the sale of medicines," omitting the concluding words of the paragraph, which will then run as follows:—

"I hereby authorise the President and Fellows of the King and Queen's College of Physicians in Ireland to erase my name from the list of licentiates; and I consent to surrender the diploma received from the College, if I shall (after having obtained the licence of said College) keep open shop for the sale of medicines."

Signed,

FLEETWOOD CHURCHILL, President.

THOMAS E. BEATTY.

SAMUEL GORDON, V.P.

WILLIAM MOORE.

R. D. LYONS.

H. HEAD.

WILLIAM STOKES.

J. T. BANKS.

F. R. CRUISE.

H. KENNEDY.

SAMUEL HAUGHTON, Clk.

31st December, 1867.

## Medical News.

Royal College of Physicians of London.—Monday, December 21, 1874.

Admitted member:—

Henry Folkard, 18 Blenheim Crescent, W.

The following Candidates for the College Licence having conformed to the bye-laws and regulations, and passed the required examinations, were admitted Licentiates:—

George Andrew, St. Bartholomew's Hospital, E.C.

Samuel Benton, Waking, Southend.

Reginald E. Wormald Brewer, Newport, Mons.

Henry Clarke, Guy's Hospital, S.E.

Henry Radcliffe Crocker, University Hospital, W.C.

Charles Henry Day, 12 Doughty Street, W.C.

Gerald Samuel Harper, 121 Warwick Street, S.W.

George W. Homan, King's College Hospital, W.C.

Thomas George Lawrence, 3 Rutland Street, N.W.

Robert Samuel Mutch, 38 Gower Street, W.C.

Charles Newman, 1 Pennywell Road, Bristol.

John Billingsley Richardson, 13 Portsea Place, W.

George Hamilton Ross, 11 Hart Street, W.C.

Henry Hammond Smith, 23 Craven Street, W.C.

Herbert Neale Smith, Richmond Villa, Brighton.

Edmund Johnson Spitta, Clapham Common, S.W.

Joseph B. Talbot, County Asylum, Shrewsbury.

John William Taylor, Charing Cross Hospital, W.C.

Herbert Henry Thomas, 26 Rutland Street, N.W.

Peter James Thomson, 52 Harrington Street, N.W.

The following candidates having passed in Medicine and Midwifery, will receive the College Licence on obtaining a qualification in Surgery recognised by this College:—

Roger Edwards, University Hospital, W.C.

William Murrell, 12 York Street, St. James' Square, S.W.

## NOTICES TO CORRESPONDENTS.

UNITED STATES COMMISSIONER IN LUNACY.—We are gratified to announce that our American correspondent, Dr. Nathan Allen, of Lowell, to whom our readers are indebted for much valuable matter from the other side of the Atlantic, has been appointed State Commissioner in Lunacy by the Government of the United States. We heartily congratulate our correspondent.

Dr. J. B. will find the subject of his letter treated in another column.

Dr. D. S.—We cannot explain the fact.

M. LE DOCTEUR CHARLES MAURIAC, Paris.—Be pleased to accept our best thanks for your brochure "On Psoriasis of the Tongue." The work shall have the review which its very high merits as a contribution to exact observation so fully entitles it to.

Dr. ABBOTT CARLETON, Boston, U.S.—Thanks for the communication. We should be glad to hear some account of ophthalmic medicine in Boston at your leisure. There is now a ladies' college for medicine in London where the pupils dissect and learn anatomy and physiology. Mr. Critchett is to lecture. There is no diploma in England yet open to women, but some English ladies are studying at Paris, and intend, we hear, dissecting in London. Two ladies, N. Kingsford and A. Vickery, the latter having already passed the examination as chemist and druggist at the Pharmaceutical Society of Great Britain, have, in November last, passed their *premier examen de fin d'année* at Paris. There is a strong opinion as yet to women practising medicine in England, but Mr. S. Anderson is said to do a great deal of "business."

Dr. W. SMITH.—Yes, the mortality in France is now very low, probably lower than in any large country in Europe. There is an equality in the number of males and females of a marriageable age in France, and emigration has not, as with us, run off with such an unfair number of marriageable men. The *Saturday Review*, about a month back, had a very favourable notice of the present economical position of France, which, according to the writer in the *Review*, had been predicted by the disciples of Stuart Mill.

R. I.—Prof. Gladstone will deliver lectures next week, on Thursday and Saturday, at the Royal Institution, "On the Voltaic Battery, Electrical Decomposition, &c." These lectures commence at 3 p.m.

A STRANGE FREAK OF NATURE.—In the case of Downing v. Ramsden, heard in the Court of Queen's Bench last week, wherein the plaintiff, a medical man, resident at New Cross, sought to recover a sum of money for maintenance and medical attendance on the wife of defendant, one of the witnesses deposed, according to the published reports in the daily papers, as follows: "In October I was living with my brother-in-law in Dunning's Alley, Bishopsgate. Mr. Ramsden came there in a cab, and was confined with twins." Whether this extraordinary piece of evidence had any effect upon the minds of the jury we know not, but the verdict reversed a previous decision, and was this time in favour of plaintiff. We hope Mr. Ramsden is well over his confinement, and able to bear with his legal defeat.

MEDICAL DIARIES FOR 1875.—In a previous number we noticed the re-issue of "Smith's Visiting List for 1875." We have now before us one or two specimens of Letts' well-known diaries, which are, in fact, too well known to need comment at our hands. Every member of the profession must perforce use a diary of some kind, and whether he use "Letts' Medical Diary" or "Smith's Visiting List," it is a matter of usage and taste. Each is excellent in its own special sphere; and we are enabled to state, from personal examination, that the latest edition of Messrs. Letts' Diaries are fully equal to their past standard of excellence.

## HOSPITAL SATURDAY.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In the very brief space which I fear is all you can allot me, I find it quite impossible to give even a moiety of the answer to your challenge which I should like; but pass on at once to the last two paragraphs of the remarks appended to the letter you honoured me by inserting in the MEDICAL PRESS of Dec. 9th. As you have challenged an instance of any benevolent office instituted and carried out by working men and their leaders, permit me to mention the various temperance organisations, institutions essentially benevolent, in the highest meaning of that phrase, inasmuch as the workers do their utmost to benefit their fellows without any hope of reward other than the good of those they work for. I should like to have written more at large, but your space is so limited, and always so well filled with subjects more pertinent, perhaps, to the MEDICAL PRESS, that I reluctantly abstain from quoting statistics (in my possession) to prove my assertions, merely pointing out that the Good Templars have spent in rent of their meeting-places alone over £20,000; and the only object in their minds is "benevolence." With regard to the "handsome competence" in the possession of "skilled London artisans," when I state the usual wages amount to 38s. per week—not reckoning the unskilled artisans—for "standing wages;" that the vast majority do not average 30s. per week; that an enormous number work away from their homes, necessitating increased outlay, as well as paying to charities, provident societies, &c., &c., from which they get a "contingent advantage;" and that the expenses of bringing up a family are to be considered in the estimate, the "handsome competence" becomes much diminished, and can only be "notorious" to those who are not compelled to meet all these expenses from the "handsome" sum of 30s. per week. I should be greatly obliged if you could at a future time grant me space to offer a few remarks on the other matters touched on in your leading article, as I have a great desire to vindicate the artisans, "skilled" and others, from being prejudiced in the minds of your readers; and as the animadversions appeared in such a high-class journal as the MEDICAL PRESS, I thought it essential the answer should have a chance of being circulated in the same direction in order to effect that which I ardently desire—the removal of, as I think, a mistaken idea.

I am, Sir, yours faithfully,  
H. F. G.

Poland Street, W.

## "FREE PHOSPHORUS IN MEDICINE."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Will you permit me briefly to correct a little misapprehension of my views which I observe in your notice of the above work, and for which I am myself answerable? Your reviewer supposes that I do not regard finely divided phosphorus as a safe form in which to administer that remedy. That is not my view; on the contrary, I say at page 104, "That the pills of reduced phosphorus already described afford an efficient, convenient, and agreeable means of exhibiting free phosphorus," &c. The terms which I have chosen to distinguish between a mass of phosphorus and pulverised phosphorus—viz., "solid" and "reduced" respectively, have, no doubt, conduced to some obscurity, since the latter term does not express any essential difference. I believe you will consider this point worth noting.

I am, &amp;c.,

J. ASHBURTON THOMPSON.

COMMUNICATIONS, Enclosures, &c., have been received from—Mr. Erichsen, London. Mr. D'Orsey, London. Prof. Christison, University of Edinburgh. Mr. Ireson, Leeds. Dr. Mitchell, London. Mr. Thos. Cooke, London. Dr. Davys, Swords. Dr. Routh, London. Mr. Henderson, Great Malvern. Mr. Blacker, Midsemer. Mr. Gale, Bath. Mr. Alfred Hasliland, Northampton. Dr. Elliot, Carlisle. Mr. Allingham, London. Dr. Bartley, Weston-super-Mare. Dr. Cousins, Newport. Dr. Hime, Sheffield. Mr. Jebb, Metropolitan Asylums Board. Dr. Campbell Black, Glasgow. Mr. Tilley, London. Mr. Hyslop, Stretton. Dr. Charles, Belfast. Dr. J. Stewart, Greenock. Mr. King, London. Dr. Bellis, Woolton. Dr. Lebeau, Paris. Dr. Adamson, Bellaghy. Mr. E. F. Bean, Paignton. Dr. Boyd Mushet, Birkenhead. Dr. Oscar Woods, Warwick County Lunatic Asylum. Mr. Miller, Benthams. Mr. Air, Kennington. Dr. Pearce, London. The Secretary Obstetrical Society of London. Dr. Madras, Dripsey. Dr. McMahon, Toomavara. Dr. Rorke, Sutton. Dr. Winslow, Scrabbly. Dr. Irvine, Irvinestown. The Bursar, Queen's College, Belfast. Mr. John Conn, Newtownlimavady. The Clerk of Union, Ballyshannon. Dr. Lyon, Willenhall. Dr. O'Reilly, Nobber. The Clerk of Union, Mohill. Dr. Evans, Dublin. Mr. Brennan, Royal College of Surgeons, Ireland. Dr. James, Kensington. Dr. Griffiths, Dublin. Dr. Fryer, Fenagh. Dr. Harrison, Kilmrough. Dr. Gray, Armagh. Mr. T. Lambert, Mercer's Hospital. Dr. Ringland, Lisbane. Dr. Jennings, Cork. Dr. Muter, London. Dr. Dudley, Kinnetty. Dr. Murdoch, Maghera-felt. Dr. Bates, Cowbridge. Glamorgan. Dr. Harvey, Cork. Rev. Dr. Haughton, Dublin. Dr. Robinson, Dublin. The Registrar, Queen's College, Cork. The Registrar, Catholic University. Mr. John Orr, Biehill. The Clerk of Stranorlar Union. The Clerk of Letterkenny Union. Mr. W. D. Wadsworth, Kingstown.

## VACANCIES.

Royal College of Surgeons of Ireland. Professorship of Midwifery. (See Advt.)  
Letterkenny Dispensary. Medical Officer. Applicants must address the Hon. Sec. (See Advt.)  
Newcastle-on-Tyne Lunatic Asylum. Assistant Medical Officer. Salary, £100 per annum, with board and apartments. Forms of application to be obtained from the Superintendent.  
Sheffield Public Hospital. House Surgeon. Salary, £100, with board and residence. Address, Dr. Hall, at the Hospital.  
Western Dispensary, Westminster. Resident Medical Officer. Salary, £105, with furnished rooms. Address the Secretary, 1 Artillery Row, London, S.W.  
Evelina Hospital for Sick Children, Southwark. Physician. Honorary. Also a Medical Registrar. Salary, £20 per annum.  
Dundee Royal Infirmary. Resident Medical Assistant. Salary, £29, with board, &c. Address the Secretary.

Essex Lunatic Asylum. Second Assistant Medical Officer. Salary, £100, with board. Applications to Dr. Campbell, at the Asylum, Brentwood.  
University of Edinburgh. Examiner in Medicine. Full particulars of the Secretary.  
Great Northern Hospital, Caledonian Road. N. Physician. Honorary. Surgeon. Honorary. Applications to be addressed to the Secretary.  
Parish of St. Pancras, London. Medical Officer of District No. 8. Salary, £180 per annum. Applications, accompanied by testimonials, to be addressed to the Vestry Clerk, at the Vestry Hall.

## APPOINTMENTS.

BLAKER, E. S., L.R.C.P. Ed., M.R.C.S.E., Acting Medical Officer to the Worcester Dispensary and Provident Medical Institution.  
BREXERTON, W. W., L.K.Q.C.P.L., Superintendent Medical Officer of Health, and Sanitary Officer for the Oughtersland Rural Sanitary District.  
BROWN, G., M.R.C.S., L.S.A., Surgeon to the Islington and North-London Provident Dispensary.  
CRACKLE, T. A., M.R.C.S.E., Medical Officer and Public Vaccinator for the No. 8, or Ilkerton District of the Bassetford Union.  
DUNLOP, W. M., M.B., C.M., Medical Officer for the Wilford District of the Woodbridge Union.  
HARVEY, A., L.A.H. Dub., Apothecary to the Rathmines Dispensary, South Dublin Union.  
LEE, F. F., M.B., Physician to the General Infirmary, Salisbury.  
LYDDON, J. H., L.R.C.S.I., Surgeon to the Norwich Friendly Societies' Medical Institute.  
MACARTHUR, P., M.B., L.R.C.S. Ed., Medical Officer, &c., for the Grey Abbey Dispensary District of the Newtownards Union.  
MAPOTHER, E. D., M.D., Consulting Sanitary Officer for the Killmainham New Urban Sanitary District.  
MCDOWELL, FRANCIS VICTOR, L.R.C.S.I., Sanitary Officer for Ballinamoyler and Newtown, Queen's County, and Consulting Sanitary Officer for Carlow Urban District.  
PIERCE, G. F., L.R.C.P. Ed., L.R.C.S. Ed., Attending Physician to the Ulster Hospital for Children, Belfast.  
ROBERTS, J., M.D., M.R.C.P.L., Consulting Physician to the General Infirmary, Salisbury, on resigning as Physician.  
STRELL, G., M.B., C.M., Medical Registrar to the London Fever Hospital.  
STURGE, W. A., M.B., M.R.C.S.E., Medical Registrar to the National Hospital for the Paralysed and Epileptic.  
WALL, J., M.D., Superintendent Medical Officer of Health for the Cork Urban Sanitary District.

## Deaths.

BAXTER.—On the 5th Dec., W. Dacier Baxter, M.R.C.S.E., of Cheltenham, aged 80.  
BEAN.—On the 11th Dec., Dr. R. J. Bean, of Lodge Street, Leeds, aged 49.  
BOYD.—On the 14th Dec., at 2 North Crescent, Bedford Square, London, Sir William Boyd, Knt., A.M., M.D., in the 72nd year of his age.  
EATON.—On the 7th Nov., at Ballinasloe, co. Galway, of inflammation of the lungs, Richard Eaton, M.D., for fifteen years Medical Superintendent of the Ballinasloe District Lunatic Asylum.  
FLEMING.—On the 18th Dec., at George Street, Hanover Square, London, Hope Stewart Fleming, late of the H.E.I.C. Medical Service.  
GARDNER.—On the 14th Dec., R. Gardner, M.D., of Johnstone, Renfrewshire, aged 83.  
GILCHRIST.—On the 3rd Dec., at Vauxhall Bridge Road, S.W., Wm. Gilchrist, L.R.C.P. Ed., L.S.A., aged 48.  
GRAY.—On the 11th Dec., Jas. St. Clair Gray, M.D., of Belmont terrace, Hillhead, Glasgow, aged 37.  
HANDLEY.—On the 6th Dec., J. Handley, L.S.A.L., of Todmorden.  
HASTINGS.—On the 20th Dec., suddenly, of heart disease, at his residence in Albemarle Street, London, John Hastings, M.D., aged 69.  
HESTER.—On the 8th Dec., Jas. Torry Hester, F.R.C.S.E., of Hastings, formerly of Oxford, aged 74.  
HUDDLESTON.—On the 15th Dec., at Barnstable, J. N. Huddleston, M.D., of Roborough, Devon, formerly of Compton Terrace, Islington, aged 67.  
ROCHE.—On the 9th Dec., at his residence in London, Thomas Roche, M.B.C.S.E., Staff Surgeon R.N., aged 42.  
RUCK.—On the 8th Dec., David Ruck, M.R.C.S.E., of Cirencester, aged 50.  
SMYTH.—On the 10th Dec., at his residence, Manorcunningham, John Smyth, Esq., M.D.  
STEEL.—On the 14th Dec., at Priory Lodge, Cheltenham, James Steel, M.D., late of the H.E.I.C.S.  
THOMPSON.—On the 8th Dec., at Bath, Dr. J. Thompson, half-pay Royal Artillery, aged 87.  
WARD.—On the 4th Dec., at Bombay, A. V. Ward, M.R.C.S.E., Surgeon-Major Indian Army and Presidency Surgeon, aged 54.

## Advertisements.

HOSPITAL SUNDAY, 1875.—NOTICE IS HEREBY GIVEN, that a PUBLIC MEETING will be held on MONDAY, the 4th day of January, 1875, at Half-past Two o'clock, in the Egyptian Hall of the Mansion House, for the purpose of settling the preliminary arrangements for Hospital Sunday, 1875, and of electing the Council, &c., for that year.

All ministers of religion in the metropolis and its neighbourhood, the authorities of the various hospitals and dispensaries, and others interested in the movement, are invited to be present.—By order.

HENRY N. CUSTANCE, Secretary.

**LETTERKENNY DISPENSARY.**—The Committee of the above Dispensary will meet on Tuesday, the 29th inst., for the purpose of electing a properly qualified person to succeed Dr. Geo. E. Carré, who has accepted the appointment of Resident Medical Superintendent of the Castlebar Lunatic Asylum.

The following appointments were held by Dr. Carré—viz.: Physician to the Donegal District Asylum; Medical Officer Letterkenny Fever Hospital; Surgeon to the Donegal Artillery, &c.

Candidates for the Dispensary may forward their Applications and Testimonials to

Lisnennan, Letterkenny  
Dec. 12th 1874.

ROBERT RAMSAY, Hon. Sec.

**ROYAL COLLEGE OF SURGEONS IN IRELAND.**—The President and Council hereby give notice that on Thursday, the 14th day of January, 1875, at the hour of 2 o'clock, they will proceed, according to the provisions of the Supplemental Charter, to elect a Professor of Midwifery in the room of Dr. Sawyer, resigned. Candidates are requested to lodge their applications at the College on or before the 7th of January, 1875.

By order of the Council,

J. STANNUS HUGHES,

Secretary to the Council.

December 4th, 1874.

## MALVERN COLLEGE.

This COLLEGE contains TWO DEPARTMENTS—the CLASSICAL and the MODERN. There is also a Preparatory LOWER SCHOOL.

There are Boarding Houses within the College Grounds, held by the Head Master and others of his Staff; a Gymnasium, &c.

Board and Tuition under 14, £80; over 14, £90. Non-shareholders pay an extra fee of £5. Special advantages for Sons of Clergymen and Home Boarders.

For further information apply to the Rev. ARTHUR FABER, M.A., Head Master, late Fellow and Tutor of New College, Oxford.

## THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.

PATRON:—H.R.H THE PRINCE OF WALES.

This Institution was founded in 1839, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of £35 per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote. Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office,

40 MOLESWORTH STREET, DUBLIN.

W. O'NEILL, Secretary.

## DUBLIN INFIRMARY for DISEASES of the EYE and EAR, Ely Place.

Ophthalmic and Aural Surgeon:

ARCHIBALD HAMILTON JACOB, M.D. Dub., F.R.C.S., Ex-Ophthalmic and Aural Surgeon to the City of Dublin Hospital.

Consulting Physician:

EVORY KENNEDY, M.D. (Hon. Caus.) T.C.D. and Edin., Fellow and Ex-President King and Queen's College of Physicians.

Consulting Surgeon:

GEORGE H. PORTER, F.R.C.S.I.; M.Ch. T.C.D. (Hon. Caus.), Surgeon in Ordinary to Her Majesty the Queen in Ireland; Fellow and Ex-President, R.C.S.I.; Senior Surgeon to the Meath Hospital.

Obstetric Physician:

JOHN CRONYN, M.D., F.R.C.S., Examiner in Midwifery, Roy. Col. Surgeons; Ex-Assistant Physician Rotunda Hospital.

Work, Income, and Expenditure for Twelve Months, ending  
June 30, 1873.

Annual number of Dispensary patients ... ..	5,847
Number of visits paid by such patients ... ..	134
Number of patients within the Infirmary ... ..	163
Number of operations performed ... ..	£37 15 0
Total gross expenditure per bed per annum ... ..	1 10 6
Average expenditure per intern patient ... ..	

The Infirmary is wholly dependent on private benefactions, and is in debt to the Medical Officer. SUBSCRIPTIONS ARE EARNESTLY REQUESTED

Established 1848.

## PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.O.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.,

&c. (KING'S COLL.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

**PRACTICES AND PARTNERSHIPS NOW OPEN** for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

Z 78. First-class LONDON PRESCRIBING PRACTICE, held by the Incumbent for many years. A Partnership introduction would be given, but the connection could not be transferred to any gentleman not highly qualified nor unless he were accustomed to the best society. The income averages about £4,500 a year. Midwifery fees from 7 to 10 guineas. The residence is well situated near the most fashionable west-end squares.

Z 79. In a fashionable watering place, an OLD ESTABLISHED FAMILY PRACTICE, the average receipts from which are between £1,000 and £1,200 a year. Midwifery having been lately declined, there is little obstetric practice, but there is scope for almost unlimited increase, if this department were resumed. The house is large, very convenient, and very near the shore; it contains twenty-three rooms, with detached groom's house, stabling, &c.; it can be purchased or rented. Ill-health and advanced age the cause of retirement. The premium would depend upon the introduction required, but no gentleman need negotiate unless he has at command at least £1,000.

Z 80. In a prosperous and picturesque district, an OLD ESTABLISHED PRACTICE, yielding in actual receipts £1,100 a year. Age the cause of retirement. Appointments bring in £62 a year. The house is well situated, contains 10 rooms, with detached surgery, offices, stabling, and large garden. Rent 40 guineas. The working expenses amount in all to about £300 a year. An effective introduction by quasi partnership or otherwise as long as may be desired. Part of the premium may be paid by instalments. The whole connection is safely transferable to a suitable gentleman, and there is great scope for increase, as there is a population of about 15,000 inhabitants.

Z 76. MIDLAND. Within 70 miles of London, with direct railway communication, in a pleasant town and district, containing about 6,000 inhabitants, a FIRST-CLASS PRACTICE, realising £800 a year. No club or parish work, and the Practice easily conducted, the fees being good. There is a convenient residence, centrally situate, at a moderate rent. The whole connection is believed to be transferable to a gentleman accustomed to good society. No gentleman need apply unless he have at command at least £1,000.

Z 77. PARTNERSHIP in a large and prosperous town within 100 miles of London. A gentleman conducting an increasing practice desires to secure the co-operation of a doubly-qualified partner. Receipts last year were upwards of £1,100, and the present year will show a considerable advance. As there is great scope for increase the Incumbent believes that the receipts could be doubled by efficient co-operation. The expenses of the Practice are moderate, as the patients reside within a short radius. Public appointments produce about £200 a year. The Half Share for transfer. Part of the premium might be left on security if the applicant were suitable.

### THE CURE OF BENT KNEE AND THE IMMEDIATE TREATMENT OF CONTRACTED JOINTS.

By J. MORGAN, M.D., F.R.C.S.I.,  
Surgeon to Mercer's Hospital, Professor of Surgical and Descriptive Anatomy to the Royal College of Surgeons, &c.

In my communication of December 2nd I have stated that no definite rule can be laid down as applicable to all cases; thus, where the adhesions are found to be very firm

Case of G. H. Bent knee of 5 years' duration.

and difficult of disruption, it may be judicious to be satisfied with an incomplete extension at any one time, as in the following example:—In February, 1873, a boy, G. H., aged nearly 10 years, came under my care, with the knee bent at a very considerable angle. He had suffered from disease of the joint for several years; it had gradually kyphosed in the position shown below.

There was very little mobility of the joint, and the boy's general health was now good. I found the biceps tendon resisting, and divided it under the influence of ether. I straightened the knee very considerably, notwithstanding a great deal of resistance. In two months the boy went to the country, and I lost sight of him till last month, when he came to me with the knee still somewhat bent; he used a crutch, though the front part of the foot reached to the ground and served in progression.

On November 29th, 1874, I put him under ether, and forcibly extended the joint, without finding it requisite to divide any tendon. I had two lateral stays applied with a cross leather padded strap at the knee; he went to the country last week, walking well, and leaving his crutch here behind him.

In this boy the deformity had been very great, indeed, apparently a hopeless case; he now walks with but a slight limp, and is gaining courage daily in using the limb.

Even a very early age does not preclude the application of this treatment, as in the following instance:—

On September 14, 1874, a child, aged six years, was brought to me to Mercer's Hospital to have its knee straightened; it was miserably neglected. At two years of age it first showed evidences of knee disease. It had thus spent four years of its life getting along as best it could, without being able to put the foot to the ground. The joint was bent, as shown in the tracing, at a considerable angle. It was capable of flexion, but not of extension. The outer hamstring was found resisting.

I put her under the influence of ether, and divided the hamstring with the tenotome, and, by extension in the manner directed, I reduced the limb at once to the straight position, and put on a support. The child left hospital on September 22, 1874. She is now able to walk,

and is improving in health, notwithstanding the adverse circumstances of an uncomfortable home.

In another instance, where there was the complication of a talipes of the same foot, the result of extension of the contracted knee was equally satisfactory.

F. H., a girl, aged 8 years, about Christmas 1869, had fallen on a fender, and hurt the knee, which subsequently became swollen and tender. She suffered a good deal of pain in the joint, and was confined to bed for several months. In April, 1870, an abscess formed in the calf of the leg, through which a drainage tube was passed. After many months she partially recovered with a contracted joint. In September, 1872, a piece of bone was removed from the front of the tibia, the child was kept in bed, and an attempt was made to straighten the knee by the application of weights and an instrument. This treatment was used for six months. An abscess formed then under the knee, and it presented the contracted appearance shown in the drawing, taken from a photograph.

Case of F. H., with contracted knee. Nov. 23, 1874.

Though the complication of the contracted tendon of the heel, owing to the destruction of the calf muscles by the original abscess, was an unpleasant one, I anticipated in this case a successful result as to the joint; there was a certain amount of mobility left, and the hamstring tendons seemed to be considerably implicated as a cause of the deformity. On November 25th, 1874, I put her under etherisation, and divided the biceps tendon, which I found

offending. I then extended the limb per force, using equable pressure around, and behind more particularly, and felt very distinctly the adhesions give way according as I straightened the joint. The limb was laid on an angular splint, which was subsequently straightened. This little patient suffered comparatively nothing, and in less than a fortnight was walking about bravely with the protection of lateral rods, and an ankle strap to help in the correction of the contracted ankle. The straightness of the limb, and the ability to support herself erect, and independently of any crutch, is shown in the drawing, taken from a photograph procured on December 3rd, 1874.

Both these instances are interesting, as occurring in children of a tender age, whose general health would be much endangered by the confinement and inconvenience caused by malposition of such a limb.

(To be continued.)

## CHOLERA: ITS ÆTIOLOGY, CONTAGIOUSNESS, AND TREATMENT.

By WM. BOYD MUSHET, M.B. Lond., M.R.C.P.,  
Late Physician to the North London Hospital for Consumption, formerly  
Resident Physician at St. Marylebone Infirmary.

### ÆTIOLOGY.

(Continued from page 549.)

The cramps, which are very variable in intensity in cholera, are due, says Dr. Johnson, to the irritant action of morbid blood, which excites spasm of the muscles; but I regard them to depend on insufficiently nourished nervous and muscular filaments, which differ much in irritability, according to the neurotic predisposition of the patient. Cramps were not so frequent or intense at the latter part as at the commencement of the epidemic of 1854. The presence of a poison in the blood in cholera, upheld by Dr. Johnson and other authors, can with difficulty be reconciled with the fact of a patient cold and pulseless, in a state of collapse, becoming, without further evacuation upwards or downwards, in a few

minutes, warm, naturally coloured, and rapidly convalescent, as I have witnessed, after a dose or two of sulphuric acid.

That saline injections act by relieving spasm of the vessels, as Dr. Johnson asserts, I believe to be altogether an error. He may as well call all passive congestion minute arterial spasm. Injections in cholera cause dilution and liquefaction of the inspissated blood, and, if hot, temporarily restore the circulation and animal heat, which last is radically interfered with by suppression of the organic operations; but their good effects are transitory, and cease as the temperature declines, as injections, says Dr. Parkes, never saved a case.

In reaction, Dr. Johnson holds that the drowsiness results from carbonic acid in the blood; but it is more probably due to reformation of effete materials not excreted, as urea, &c. It is, in fact, uræmic, not asphyxial.

To sum up, I regard cholera to be a malignant form of diarrhœa, essentially identical in its nature, arising from a local trophic perversion of the alimentary canal, in consequence of the introduction of putrescent animal particles into its interior (occasionally through the lungs?), which, under some inscrutable influence or epidemic constitution, destroy the balance of the capillary circulation of the stomach and intestines, causing exhalation from their surface, attended by characteristic symptoms, one of the most marked and constant being, in the stage of collapse, suppression of urine. The general symptoms of cholera are almost or complete pulselessness, haggard visage, eyes sunken, with striking areolæ, features pinched, lips livid, voice whispering, surface more or less mahogany blue in tint, and cool, extremities cold, nails purplish or black, skin corrugated, tongue variable (may be clean), cramps in legs and abdomen (may be absent), great distress and restlessness (variable), great thirst, gruelly or rice-water evacuations, vomiting as if the whole stomach was abruptly emptied without effort, succeeded by retching, frequent moaning, and suppression of urine. In rare cases the dejecta are bilious throughout in the fatal form of the disease, but anuria is constant, and it is evident that the diminution of the renal secretion is directly proportionate to the severity of the collapse, that is, to the completeness of the arrest of nutrition and of the organic functions. No urea is formed, and no urine is secreted, as the kidneys lack their accustomed stimulus. When consecutive fever supervenes, with restored tissue metamorphosis, there is difficulty of varying grade in re-establishing the renal function, and the urine is always albuminous. Hence there is a disposition to uræmia; in collapse, anuria; in reaction, ischuria.

The consecutive fever, however, is frequently out of proportion to the intensity of the antecedent collapse. It is at times severe, even after choleraic diarrhœa. I believe the consecutive symptoms depend much on their severity whether the stage of reaction has been of gradual or sudden invasion, on the mode of treatment adopted, and also on the previous condition of the kidneys, though other influences may contribute. Although the mammary secretion is not arrested in malignant cases, as Dr. Johnson has pointed out, *it is rendered serous*. I noticed this in a severe, but not one of the severest cases.

Do children under two years ever exhibit the characteristic (cyanotic) symptoms of cholera? I have observed several cases of diarrhœa of unusual severity in infants which proved fatal during the epidemic, whose mothers had died from the disease, but the type did not justify the appellation of malignant cholera. I may add that the disease did not spread from these to other children in the nursery.

Dr. Ayre held that cramps were also invariably absent from children, and certainly, according to my own observations, they do not present the characteristic symptoms remarked in adults.

#### Contagiousness.

With regard to the contagiousness of cholera, there is a remarkable diversity of opinions. It is, of course, exceed-

ingly difficult to prove a negative, that is, that it is *not* contagious. On the other hand, it is almost as easy to conclude affirmatively, when an outbreak occurs, and a large number of the population is attacked within a limited area, often on most insufficient grounds, as in the case of the Broad Street pump, the water from which almost simultaneously affected several hundred persons. It is also significant that those who are most conversant with the disease in England are either non-contagionists or regard it to be but mildly contagious, whilst those who have had little or no experience of cholera are firmly persuaded of its contagiousness, as were for the most part our predecessors, when panic-stricken by its appearance at Sunderland in 1831. Thus, in 1832, the College of Physicians affirmed the disease to be contagious, whilst the Committee for Scientific Inquiries in 1854 were undecided on the point. It may also be noticed that the views of authors as to contagion are often influenced by their special theories concerning the disease. Amongst old Indian medical officers, Annesley and Jameson were non-contagionists, whilst Orton was inclined to contrary views. Dr. Roupell believed cholera to be contagious, but he admitted that it may have had more than one source, and appeared in many places independently of transmission or contagion. He owned that "military cordons, and most rigorous continental enactments have proved inefficient in preventing the spread of the disease from infected to uninfected countries," which is an argument rather against its propagation by contagion.

Dr. Parkes, on the contrary, from his observations in India, does not consider the disease contagious. "He has never observed any indication of contagion." He says that communication with infected persons or districts did not cause the disease. He has inoculated himself accidentally in post-mortem examinations and never suffered; nor did the hospital attendants or medical officers. He does not, however, wish to generalise his observation and to conclude that the poison of cholera is never reproduced in the human body; but he has never witnessed any facts which led him to believe that the poison of cholera possessed the power of multiplying itself by its action on the living human system.

Dr. Copeland believed pestilential cholera to be a specific disease, distinct from the severe forms of common cholera. He deemed it infectious, and essentially independent of epidemic influence, or of any particular state of the atmosphere, although it may be intensified thereby.

Sir Thomas Watson, Dr. Bryson, and Dr. Geo. Johnson all appear to be contagionists, that is, hold that cholera is a portable poison, capable of conveyance from place to place and of communication from person to person; and Dr. Bryson asserts that "its spontaneous origin far away from an infected locality is unknown in the naval service."

(To be continued.)

## FRACTURE OF SKULL FOLLOWED BY HERNIA CEREBRI.

By JOHN G. ADAMSON, A.M., M.D.

On the evening of Sunday, Aug. 23rd, Samuel B., a young man about 19 years of age, but unusually tall and muscular, came to my house to have a wound on his head dressed. He had been fighting, when his opponent struck him a severe blow on the head, apparently with some weapon, which felled him to the ground, but he immediately arose and resumed the quarrel for a few minutes. He then got into a cart and went about half a mile. So little did he think of the wound that it was only when urged by a friend he consented to come to me to have it dressed. On examination I found a scalp wound about two inches in length, over about the middle of the left parietal bone, leading down to a depressed fracture of the skull. Finding a number of loose frag-

ments of bone, I removed them—nine in all—but as the patient suffered no pain I did not consider chloroform necessary. A gap in the skull was left, somewhat circular, about one inch in diameter, and at the bottom were seen portions of brain substance which had escaped through lacerations of the membranes. During the whole examination and removal of bone the patient was perfectly conscious, and constantly expressed himself as absolutely free from pain. For a moment or two he became somewhat faint, but soon recovered. I applied simple water-dressing, had the patient removed to a friend's house a short distance in the country, and ordered for him a saline aperient.

Aug. 24th.—Found him quite conscious and free from pain; had had a good night and slept well; bowels freely moved. Ordered for him tinct. ferr. mur., with the idea—as suggested to me by my late teacher, Dr. Gordon, of Belfast—of its acting as a sort of prophylactic against erysipelas.

Aug. 27th.—A little pus appeared in the wound, with slight fœtor; general health and appetite good; complained of no pain; continued tinct. ferr. mur., and ordered carbolio lotion to be applied to the wound.

Sept. 3rd.—Till this time case had progressed without a single bad symptom; pulse and temperature normal; wound had closed in considerably, and appeared healthy.

Sept. 5th.—To-day I found patient in a semi-comatose condition; could with difficulty be roused to consciousness; I examined the edges of the wound in skull, and found a spiculum of bone projecting into the brain; shortly after the removal of this, perfect consciousness returned.

Sept. 16th.—Nothing worthy of note since 5th; he was somewhat weaker, and stomach rejected all food almost as soon as taken.

Sept. 22nd.—Wound in scalp had almost closed, but seemed rather fuller than formerly. Fearing hernia, I applied a pad, which did not give any annoyance. Appetite still fair, but irritability of stomach continued.

Sept. 26th.—Patient weaker, and vomiting persistent; total paralysis of right side, but consciousness remained perfect, and he answered rationally when addressed. Hernia was increasing, and I found it impossible to re-apply the pad tightly, in consequence of the extreme nervous irritation occasioned thereby. There had been several pretty severe attacks of hæmorrhage from it during the past few days.

Sept. 28th.—Hernia so large that I deemed it advisable to remove the protrusion, which I did by shaving it off level with the scalp, and re-applied the pad, which now seemed to be borne somewhat better. Patient much emaciated, and very weak.

Oct. 3rd.—He seemed to be sinking gradually; though he appeared to understand all that was said, he had not the power of replying except by signs. On several occasions I was told he had attacks of violent delirium; indeed, so unmanageable had he been that one of his friends suggested to me in all sincerity the propriety of administering a dose to put an end to his sufferings with his life. When seen by me, however, he was very quiet, and remained so till his death. He lay in a semi-comatose condition, but could be easily aroused.

Oct. 8th.—Hernia had entirely disappeared, and instead there seemed to be a considerable loss of brain substance. He was unconscious, fœces and urine being passed involuntarily.

Oct. 11th.—He died to-day, at 4 o'clock.

Oct. 12th.—Made a post-mortem. Found slight congestion on surface of right hemisphere of brain, and on left side found a cavity in brain, somewhat conical in form, the base about two inches in diameter, corresponding to the seat of injury in the skull. On removing the brain a quantity of pus escaped, which came from an abscess in the left anterior lobe, which had almost entirely destroyed the third convolution and injured the others to some extent also.

Remarks.—The first point of note in this case was the

amount of injury inflicted on the brain and its membranes without the patient being aware of it or experiencing any pain, and the entire absence of pain even during the removal of the fragments of bone.

2. The long time which elapsed from the receipt of the injury till death ensued. This I am inclined to attribute to the strength and vitality of the patient.

3. The loss of the power of speech, together with the existence of an abscess in the situation described, seems to give some support to the theory advanced by M. Broca, that the seat of the faculty of articulate language is in the posterior part of the third frontal convolution of the left lobe of the brain. From a case, however, in which the brain had sustained such extensive injuries, it would be impossible to arrive at any definite conclusion, though the coincidence is worth mentioning.

## CLINICAL MEMORANDA.

Reported by JOHN W. MARTIN, M.D.,

Assistant-Surgeon Mayfield Factory Dispensary, Portlaw, &c., &c.

### *Case of Retained Placenta—Hour-glass Contraction of the Uterus.*

On the 24th of October, 1874, I was asked to see the patient, M. K., by the midwife in attendance, the placenta being retained. The nurse stated that the labour had lasted forty-eight hours, that the case had been one of breech presentation, and that the child had died immediately after birth. (I strongly suspect myself that the child was still-born.) I saw her about an hour after the birth had taken place; during the interval she had lost a great deal of blood, and was very low and weak.

After a fair trial of pressure, cold applications to the surface of the abdomen, gentle traction upon the cord, &c., without the slightest effect, I introduced my hand into the uterus, and brought the placenta away.

The case was one of well-marked hour-glass contraction, the constriction being high up in the middle zone of the uterus; by it the after-birth was tightly grasped, and impossible of removal save by the introduction of the hand. After removal of the placenta, there was good contraction, and the case did well. It may be as well to remark that the woman had married rather late in life, to which circumstance in part may be due the prolonged labour.

## Hospital Reports.

### METROPOLITAN FREE HOSPITAL.

(Under the care of Dr. CHARLES R. DRYSDALE.)

JAMES GERRARD, set. 47, came to the Metropolitan Hospital on the 13th of November, 1874. For the last six months this patient has noticed a sore at the right commissure of the mouth, which he attributes to having put in his mouth a pipe in a public-house. The mouth did not get sore for a month after the pipe was used, and has been so since. The sore has been hard all along for the last six months, but there has been no lump beneath the jaw. At present, there is a very slight loss of substance, caused by an ulceration occupying the right commissure of the mouth, and both on the upper and lower lip there is a red swelling visible, both of which are slightly oedematous. No enlarged glands. The diagnosis in this case seeming to lie between cancer and syphilis, Dr. Drysdale prescribed three grains of blue-pill with two of extract of hyoscyamus twice daily, and awaited events. The man never returned. It is probable that this was a case of syphilitic infection by a dirty pipe.

CASE 2.—CATHERINE MARTIN, set. 37, came to the Metropolitan Free Hospital on the 14th of April, 1874,

bringing with her an infant aged seven weeks, suffering from a dry eruption on the face, buttocks, feet, legs, and back of neck, where it is profuse. The child snuffled a good deal, so that it could hardly suckle, especially at night. This eruption appeared when the child was five weeks old, first on the buttocks.

The mother has been married three years. Her husband is a labourer. She has one little boy a year and eight months old, quite healthy. Husband was in St. Bartholomew's Hospital twelve months ago with asthma. He is reported not to have any eruption. Mother says she was well whilst pregnant with this infant. Dr. Wathi prescribed hyd. c. cret., gr.  $\frac{1}{2}$ , bis. d.

On April 21st, a few little vesicles were seen on mother's left breast. Child is said to be a little better since taking this powder. The next entry, on the 27th of April, mentions the death of the child.

*Remarks.*—Hereditary infantile syphilis is a very fatal disease under all treatments. It is a pity that so many able men have written so incautiously as to make it seem as if it were very easily cured by small doses of mercury. Such is not the case, and the great majority we think of syphilitic infants die.

### CASE 3.—*The White Patchy Tongue.*

MARY WELLAND, æt. 40, married. Has usually had good health until latterly, but has never complained of her tongue. Came to the Metropolitan Free Hospital in November, 1874, for bronchitis. There is a large central strip of whitish appearance, as if the tongue had been painted over with a weak solution of nitrate of silver, one inch in breadth, extending from the circumvallate papillæ to half an inch from the top of the tongue. The patient feels no inconvenience from this condition of tongue. She never has suffered from skin eruptions, nor is there any special history leading to the suspicion of syphilis.

### CASE 4.—*An Excessive Beer-Drinker.*

IN October, 1874, a man, æt. 50, a coal-whipper on the Thames, attended the hospital affected with phthisis pulmonalis, which seemed to have been caused by immoderate drinking. The patient asserted positively that for a week at a time he had occasionally drank six or seven gallons of beer daily.

## Transactions of Societies.

### THE SURGICAL SOCIETY OF IRELAND.

THE opening meeting of the Surgical Society of Ireland for the session of 1874-75 was held on the evening of Friday, the 4th of December. The President of the College of Surgeons, Dr. JOLIFFE TUFNELL, occupied the chair.

The PRESIDENT delivered the opening address, which we published in our last issue.

Mr. WHEELER brought forward

#### A CASE OF ELEPHANTIASIS ARABUM.

The subject of this case was a woman, thirty years old, who was admitted under his care on the 16th of October, 1874. He states that she continued to suffer from the disease for a period of eighteen years. Her father was alive, the mother died after confinement, and the rest of the family were all healthy. The disease began with a pain in the foot, when the patient was 10 or 11 years old, the ankle then swelled, again subsiding and again enlarging. She suffered during this period from the fever known as elephantoid fever, which continued periodically for about a year and a half. The disease appeared to become stationary as regards enlargement for about two years, and afterwards the pain commenced anew and the limb continued to enlarge, but not going further than a little above the ankle-joint. The "crvice," as it was called by Virchow, formed at the inner malleolus, and the folds of skin lying on one another caused ulceration. A large excavated ulcer now formed, five inches in length and four in width, and pieces of bone came away in the vicinity of the ulcer. It appeared

that in this case elephantiasis preceded ulceration, and higher up in the limb the ulceration preceded the elephantiasis. In that he could only reason analogically, inasmuch as the tissues of the limb where he amputated were perfectly healthy, and as the disease had been stationary for some time in the limb a little above the ankle, before ulceration of the superior part of the limb commenced, it would appear that in this case ulceration preceded elephantiasis. In this case the limb was immensely developed, the blood-cells and reticular connective tissue, with the fascia over the gastrocnemius muscle, was enormously thickened, and its elements, more lax than ordinary, were abundant in intercellular substances. The tunica adventitia of the blood-vessels, popliteal artery and vein was very much thickened, otherwise the vascular coats were normal. The size of the sound limb as compared with the diseased was as follows, in inches: Sound—round ankle, 8 $\frac{1}{2}$ ; round calf, 13; round dorsum of foot, 9 $\frac{1}{2}$ . Diseased—round ankle, 20; round calf, 26 $\frac{1}{2}$ ; round dorsum of foot, 18 $\frac{1}{2}$ . The operation was performed on Nov. 3rd, 1874, the patient being placed under ether by Mr. Richardson's apparatus, which is considered, in the City of Dublin Hospital, as the best apparatus for the administration of ether. Three small vessels were ligated with the femoral artery, and an enormous quantity of venous blood flowed from the femoral vein, which after some time ceased when the limb was elevated. After the operation the patient suffered from some collapse, pulse feeble, perspiration over face and trunk, lips anæmic. By the administration of stimulants she came round gradually, has since been progressing favourably, and is at the present time able to sit up in her bed.

Mr. WHEELER brought forward a second specimen, the particulars of which are as follows: The subject of the operation was a boy, 18 years old, who was admitted under his (Dr. Wheeler's) care on September 24th of the present year, suffering from disease of the knee-joint. The previous history of the patient showed that he had synovitis from a fall on ice, aggravated by a second injury incurred by falling from an axle-tree of a car. The condition of the patient upon admission was as follows: Pulse 124, temperature 102°, night sweats, bad appetite. There was an attempt made to place the limb upon a splint (MacIntyre's), but this caused so much pain that it had to be abandoned. Tonics were administered, and after some time the health was slightly improved. The difference between the sound limb and the diseased was as follows: The circumference below the patella of sound limb in inches was 11 $\frac{1}{2}$ ; round the joint 13; above patella 12 $\frac{1}{2}$ . Diseased limb—below the patella 13 $\frac{1}{2}$ ; round joint 17 $\frac{1}{2}$ ; above patella 15 $\frac{1}{2}$ . The diseased member was between four and five inches shorter than the sound, and perfectly useless to the patient. There was a slight pain complained of, and traction of the limb, but there was no intense suffering. The pressure on the head of the tibia caused considerable pain, and there did not seem to be much thickening of the periosteum of the femur. On Nov. 27th he (Mr. Wheeler) amputated the limb, having placed the patient under ether with Mr. Richardson's apparatus. The operation was performed by the bloodless method, with Esmarch's apparatus. He (Mr. Wheeler) first endeavoured to save the limb by resection; having had the full consent of the patient, as the President was aware, determining, if resection failed, to amputate the limb. At about five o'clock in the evening of the same day he found the patient suffering from hæmorrhage of so profuse a character that he saw the life of the patient was in imminent danger. Having compressed the femoral artery, he quickly opened up the stump and secured there a large vessel. The patient afterwards had a slight attack of rheumatism in his left wrist and right shoulder, but is since improving rapidly.

#### CANCER OF MALE BREAST.

Dr. MAPOTHER said: This scirrhus breast I removed last September from a man aged 35, who had been sent to my wards in St. Vincent's Hospital by Dr. Ryan, of Tipperary. It was two years growing, and had ulcerated a month before admission. The tumour most easily peeled off the pectoral, as in the male there are none of the suspensory bands which support the heavier organ of the female. There were four or five hard glands immediately along the axillary vein, which I thought safer to leave there. Since the amputation they have softened and lessened. The early age of the man and the size of the cancerous mass may make the specimen worth placing in the museum, although we have a few of the same kind, including one which must always create a painful interest in this Society.

Mr. H. GRAY CROLY said he wished to bring before the Society

A CASE OF ACUTE TETANUS,

which carried off the patient in twenty-eight hours; and as it occurred in a female without any well-marked cause, and the symptoms were very severe, he thought it was worth placing on record, and should be glad to hear from the experienced surgeons present anything that could throw light on this formidable disease. Martha Cullen, a married woman, æt. 30 years, residing at Kingstown, was admitted into the City of Dublin Hospital on the forenoon of Wednesday, Nov. 4th, suffering from tetanus. On examining the patient for any cause of the attack, a small, unhealthy, painful ulcer was found on the inner malleolus of the right side. The structures in the neighbourhood had an unhealthy, puffy, and dark appearance, and the foot was somewhat swollen; no other cause could be found. On examining the condition of the sufferer, she was found to be labouring under considerable trismus, the jaws being tightly locked, and the muscles of the neck were also in a state of spasm, causing a degree of opisthotonos. The eyes were partially closed in that forced way so characteristic of the affection, and the corners of the mouth were drawn up, causing the face to assume the "risus sardonius." The brow was wrinkled both longitudinally and transversely, showing spasm of the occipito-frontalis and corrugator supercilii muscles. The whole expression of face was strangely altered. On inquiring from her when and how she first became affected, Mr. Croly learned with some difficulty, owing to the trismus, &c., that it had commenced on the previous morning by frequent stretching and yawning, and a feeling of general malaise, which soon developed into the conditions described. She had the characteristic sputtering cough, after which a quantity of viscid frothy mucus would be extruded through the closed teeth, which required to be frequently removed with a cloth. She was immediately carried up to a bed, round which were ordered to be placed screens, and carpet on the floor, to keep an even temperature and avoid noise. A fresh poultice with some tincture of opium spread on it was applied to the ulcer, a hot jar to the feet, which were cold, as were the hands, and a bed-rest was placed behind her, she finding the breathing easiest in the semi-sitting posture. Some whisky and beef-tea were administered in small quantities through a convenient gap which existed on the left side of her mouth, the teeth being absent. This means, however, soon failed, in consequence of the spasms of the glottis caused by the slightest drop of fluid being introduced, which fluid she kept gurgling up and down in her throat for some seconds, and then extruded with the frothy mucus through her closed teeth. Mr. Croly ordered an enema to be given as follows: Olei terebinthinæ, ʒiv.; tincturæ assæfœtidæ, ʒij.; olei olivæ, ʒi; magnesiæ sulphatis, ʒiv.; decocti hordei ad. Oj. Also a draught consisting of chloralis hydratis, gr. xxx.; syrupi Tolutani, ʒj.; aquæ menthæ pipéritæ ad ʒss. Wine and milk were ordered, ad libitum, but only small quantities of the wine and milk were administered, owing to the difficulty of deglutition. The enema was administered, and in some time brought away a considerable quantity of feces of a natural appearance. In the evening Mr. Croly again saw the patient, and finding that she had not passed any urine since she came in, introduced a catheter (No. 9 gum-elastic male) and drew off about three-fourths of a pint of urine. He then ordered her nutritive and stimulating injections, and sinapisms to be applied to the calves of the legs and over the epigastrium. To relieve the violence of the spasms, which were now very distressing, he gave her a few whiffs of ether with Mr. Richardson's apparatus. The following is a concise account of the time and duration of the spasms, as observed and noted by Mr. Arthur H. Benson: From 8 to 9.10 p.m. she had had four exacerbations; the next was at 10.15, violent, 2m. 10s. duration; she then had an enema of whisky and beef-tea. At 11.15 she had another spasm, shorter and less severe than the former, 1m. 30s. duration; the pulse was 148, hands deadly cold and clammy, forehead perspiring profusely, and cold; an enema of whisky and beef-tea, quinine and belladonna was administered. At 12.5 p.m. she had another severe spasm, 2m. 15s. duration, pulse 154, hands, face, and feet cold and clammy. At 12.30 she had a spasm, longest of all in duration, lasting 4m., but with a period of tranquillity in the middle lasting 1m. 30s., pulse 180, respirations 51 per minute. 12.45, short and sharp, 1m. 30s. duration, pulse 152, difficult to count; beef-tea and whisky enema administered. 12.58, 1m. 35s. duration, pulse 160. 1.5, 2m. duration; pulse

stronger. After this she fell asleep for a while. At 1.34 there was a final violent struggle, during which the power of distinct speech seemed for a moment to return, for she called out quite distinctly, "Nurse, don't leave me," after which she relaxed her iron grip of the nurse, and falling back on her pillow, expired in a few seconds, at 1.35 p.m. on Nov. 5th. The post-mortem examination was performed next morning by Mr. Barker, who removed the brain and spinal cord together. On examining the dura mater, when the calvarium was removed, it was found to be engorged with dark fluid blood, the basilar artery was atheromatous in some places, and when opened a gush of black fluid blood escaped. The meninges were injected, and the brain and spinal cord, when opened, were found to be congested. Mr. Croly proceeded to say that in such a case as this there was little hope of benefit to be derived from any treatment, and that he could not make up his mind as to the exact cause of the tetanus. The President would remember some cases of tetanus which he (Mr. Croly) had seen under the care of the President and of the late Professor Hargrave. The first case was that of a child who had been severely burned over the abdomen. The sufferer was kept under the influence of chloroform, the only effect of which was that it relieved the spasms for a time and allowed the mouth to be opened, but on the introduction of fluid the spasms came on as severely as ever. The second case was that of a man who had a compound fracture of the leg, under Dr. Hargrave's care. The question of amputation was considered, but it was determined to endeavour to save the leg. The man got well-marked trismus, but he recovered and had a useful limb. The third case was one of a boy who was wounded by a hook when hanging up a piece of meat in a butcher's stall. He was kept under chloroform, and made a good recovery. The fourth case was caused by burns. The fifth case was one of injury to the thumb, which proved rapidly fatal; it was under the care of Dr. Hargrave. The sixth case was that of a man who suffered from an ulcerated foot, and who died rapidly. The seventh case was that of a lacerated foot where the opisthotonos was so great that the man was thrown out of his bed. The eighth and ninth cases, one of which was under his (Mr. Croly's) care, occurred in a tan-yard, where the individuals were obliged to work in cold water, and were then exposed to hot water. Both of these were well-marked cases of tetanus; both recovered, and one of them still retained the peculiar grin on his face characteristic of the disease. The tenth case occurred under the care of Dr. Hargrave, and followed amputation of the breast, which was rather unusual. The eleventh case was a compound fracture of the leg; and the twelfth case was also a compound fracture of the leg, in which the tibia was involved. The thirteenth case was a compound fracture of the finger; the finger was amputated and fatal tetanus supervened. He should say, from his experience, that all cases of acute tetanus were fatal. The cases that recovered were those in which the symptoms were not very strongly marked. With respect to the premonitory symptoms, some surgeons laid it down that difficulty of deglutition was the most decided, and others attached importance to frequent yawning and stretching of the limbs. The yawning, he had no hesitation in saying, was a premonitory symptom that should be most carefully attended to. If they anticipated tetanus, it was clear that preventive treatment would be most important, and he thought that the anti-tetanic pill suggested by the late Mr. Peile had hardly received the attention it deserved. Mr. Croly having stated the composition of the anti-tetanic pill, said that he had put a patient who had received a wound by standing on a rusty nail, and others suffering from compound fractures and punctured wounds of the palm of the hand, on the anti-tetanic treatment, and they had not been attacked by trismus, but, of course, that was not conclusive. He knew that tetanus had occurred when the wounds were of the most trivial character, even when the skin was not injured, so that they could not say what wound might produce it. Some attributed tetanus to irritation of the spinal cord; but they had had experience of wounds of the cord where no such result followed. Mr. Croly concluded by saying he should be glad to hear the opinions of the members of the Society as to any simple line of treatment to be adopted in these cases.

Dr. ROBERT McDONNELL said he was probably the only one present who could say that he had ordered over and over again from Dr. Peile's dictation the anti-tetanic pill. He was the last pupil of that gentleman, and had frequently ordered it from his dictation. Calomel, in small quantity, always

formed a portion of the pill, the other ingredients being the same as those mentioned by Mr. Croly. Dr. Peile told him that he had never known a case of a lacerated wound in which the anti-tetanic pill had been given to have been followed by tetanus, and he was a man who lived to a great age, was a long time connected with a large hospital, and had had great experience as a surgeon.

Dr. STAPLETON remembered a surgeon in Jervis Street Hospital, a namesake of Dr. McDonnell's, who never got a case of lacerated wound in which he did not administer the anti-tetanic pill containing a small quantity of calomel. He was, however, most unlucky, for, although he always gave the pill, he had more cases of tetanus than any of the other surgeons. He did not believe there was such a thing as a tetanic wound. He had seen persons torn almost limb from limb who recovered, and he had seen a girl who only sustained a slight abrasion of the skin, which did not even bleed, die of acute tetanus. He believed that where there was a compound fracture, with a spicula of bone irritating the nerve, the patient would be liable to tetanus, and these were the cases in which, if amputation had been performed, the patient would have recovered.

Dr. RAWDON MACNAMARA believed that a most important factor in the production of tetanus was atmospheric influence; they constantly met with cases of the most extraordinary compound fractures which got well satisfactorily in one condition of the atmosphere, whilst in another condition a very trivial wound would produce tetanus. He thought they were in the infancy of that description of science, and believed the time would come when they would understand what it was that tended to the production of tetanus in wounds at one period of the year, and why it was that wounds of a similar or more severe nature would not develop the disease at another period. It had been proved by statistics over and over again that in some large hospitals the simplest operation could not be undertaken without the development of tetanus, and he believed that this must be due to some peculiar condition of the atmosphere. With regard to the treatment of tetanus, that was a most important question, and he should like to hear from Mr. Croly why he had omitted ice in the treatment of the case? With regard to the use of chloroform, he (Dr. Macnamara) believed he was the first person who had ever employed it in the treatment of tetanus. He had been sent for by Master Fitzgibbon to see a carter in his employment who had received an injury: finding the case was one of tetanus, he had the man brought to Jervis Street Hospital, where he was placed under the care of Professor Power. It was about the time that chloroform was first introduced, and he suggested its employment to Professor Power. The effect was most extraordinary; the man's face became quite livid, and respiration seemed for a time to be perfectly suspended. Since then he had seen chloroform used in cases of tetanus, but he had always dreaded it. He suggested that the Society should devote a night to the special consideration of the treatment of tetanus, which might be looked upon as one of the opprobria of surgery.

Mr. CORLEY said that in many cases of fatal tetanus the disease was anticipated by the patients themselves.

Dr. BARTON said that within the last month he had a case of amputation followed by trismus. In that case yawning was the first symptom, and was noticed the day before the trismus became marked, but he could not say whether there was any stretching of the limbs. Chloral was used, and hypodermic injection employed, so as to control the spasms, but the patient died, apparently worn out.

Dr. O'LEARY mentioned a case of trismus which had come under his observation, caused by a very extensive burn. The woman could not use her arm; she had yawning, and had an impression on her mind that she would get lock-jaw; then her neck became stiffened and she was unable to open her mouth. This passed off for a time, but in two hours afterwards she got another attack, with severe spasms of the larynx. Mr. Croly saw her with him the next day, and she died of spasm of the larynx sixteen hours after that, and forty hours after the trismus had set in.

Dr. HENRY KENNEDY said that Mr. Lockhart Clark, having investigated several cases of lock-jaw, had invariably found extensive mischief in the spine, and this pointed to treatment by ice as being likely to prove beneficial. He believed that when medicine could not be given by the mouth the best mode of administering it would be by subcutaneous injection, as administration by the rectum caused intense pain, not only in the sphincter, but in the bowel itself, which was often thrown into a state of convulsive action.

Mr. E. HAMILTON, V.P., concurred with Dr. Macnamara as to atmospheric influence in the development of tetanus. It was a well-known fact that, some years ago, in London, in an immense number of cases where the ligature was applied, tetanus followed, and that fact had been brought forward as a strong argument against the use of the ligature, whereas tetanus was very prevalent in London at that time, and its prevalence, he believed, was due to a certain condition of the atmosphere.

Mr. CROLY, in reply, said that the late Professor Hargrave always objected to the anti-tetanic pill, because it contained calomel; but he believed the original pill of Mr. Peile did not contain calomel. With regard to Dr. Stapleton's observations, he thought that gentleman would agree with him that there was a certain class of wounds which they were more or less afraid of being followed by tetanus. The reason ice was not used was because it would lower the temperature, and the condition of the patient being extremely low, it was not considered advisable to employ it, and for the same reason he did not use nicotine. He did not believe there was any specific remedy for tetanus. The acute cases baffled all treatment. Chloroform did not exercise a curative action, and it was objectionable because it depressed the action of the heart, while ether stimulated the heart's action, and was therefore preferable. He had not tried the subcutaneous injection, preferring, in fact, to keep up the patient's strength by stimulants rather than trying to treat the symptoms, which he believed there was but little use in doing. He believed that cold had a great deal to do with the production of tetanus. It was stated that the inhabitants of the Tongo Islands were peculiarly liable to tetanus, and were in the habit of treating it by introducing a reed into the urethra. Mr. Wallace mentioned that he had introduced a bougie smeared with red precipitate ointment into the urethra in a case of tetanus; the spasms were very severe; but in twenty minutes after the introduction of the instrument they became less frequent, and finally disappeared; but he omitted to say whether the patient finally recovered.

Dr. HENRY KENNEDY read a paper on

#### THE DIFFERENCE OF THE RESPIRATORY MURMUR IN THE TWO LUNGS.

In the year 1837, when Dr. Stokes' very able work on the lungs appeared, there was a statement in it to the effect that the greater number of individuals had stronger breathing in the left than the right lung. This most important statement seemed, from some unaccountable reason, to have been overlooked, for not a single author, as far as Dr. Kennedy was aware, had noticed it, or named Stokes in connection with the point. In 1867 Flint states that on examining some twenty-four persons he found, somewhat to his surprise, that in the great majority the vesicular murmur was loudest in the left lung. Again, in the last edition of Walshe, which appeared in 1871, the author states he had grounds for changing the opinions advanced in former years, for that he now believed the respiratory murmur was sometimes stronger in the left than the right lung. This was all the notice Dr. Kennedy could find bearing on the point; and as it seemed to him a question of much interest, not to say importance, he had, some years back, spent a considerable time in examining and tabulating a large number of cases. Unfortunately, the notes relating to two-thirds of these cases had either been lost or mislaid, and so the paper now brought forward was not at all as complete as it would otherwise have been. The number of cases he could now speak of amounted to about 100: of these, in nearly 80 per cent., the breathing was strongest on the left side, and in 20 of these, again, there was a very decided increase in its intensity on same side, which he had indicated by the plus mark. He thought it but right to state every means had been taken to make the observations accurate. For the opportunity of carrying out these investigations he had been indebted to his friend Dr. Shannon. The author then went on to say that he believed the original observation of Stokes to be correct, and for his part he had acted on it for many years, and in several instances was able to declare that the phenomena observed, which consisted in the greater intensity of the vesicular murmur on the left side, was quite consistent with a perfect state of health. This in itself was no slight matter, and more particularly where other circumstances might lead to the idea of the invasion of phthisis. All these points, however, were to be found fully discussed in the work to which he had so often referred.

The Society then adjourned.

## THE FROST AND THE DEATH-RATE.

WE showed a week or two ago the great part played by extreme cold in cutting short the lives of the weak at the two extremes of life; and this important point has been kept before the attention of the public for the last fortnight by the unwonted rigour of our winter. With the thermometer showing a cold of some fourteen degrees below the freezing point of Fahrenheit's scale, we can easily judge what a number of feeble old persons and young children must have succumbed in the struggle for existence, which Mr. Darwin has so clearly shown to be the cause of so many of the phenomena of man's existence on this planet.

These considerations make it clear enough that the main problem of the science of hygiene should be to get so entirely rid of misery and indigence that the death-rate in winter should show no great increase over that of summer. Among the rich, and those who can afford warm rooms and plenty of woollen clothes, the death-rate is probably but little raised by the lowest temperature ever attained in our climate. A rich person with tendency to bronchitis can, by coal fires and well-constructed apartments, enjoy all the year round a climate suited to the wants of his feeble lungs, and may reach old age and scarcely ever be in danger from the vicissitudes we have latterly undergone; but a poor person, dwelling in a miserable hut, with scanty clothing and wretched food, is totally unable to withstand the excessive cold, and is suddenly carried off by suffocative catarrh or spasm.

There is certainly no immediate prospect of any European state attaining such an ideal absence of poverty as that we have hinted at. It was hoped by many that the condition of Ireland was exceedingly ameliorated; but recent reports would tend to show that the condition of the peasantry and townspeople in many Irish towns is still frightful to contemplate. The dismal tidings, too, recently sent us from Glasgow and other Scottish cities has filled many a sanitarian with dismay; and the less we say about the condition of Liverpool, Leeds, Manchester, and Birmingham as to health the better. Our British population at present, in addition to the evils of filth and extreme destitution, is, it must be confessed, terribly kept back by the insane love of strong drinks, which seems, indeed, in

Britain and in Holland to arise from some historical and local causes, probably combined with the very inartistic training of the populations of these countries.

In the midst of all these sad facts it is cheering to hear that progress in public health still continues in spite of such numerous exceptions. A few years ago it would have, we suppose, been thought that every European nation was happier than poor France. According to shallow critics, that nation was now effete, and must be wiped away from the catalogue of civilised states. The volumes of elaborate statistics which M. Block has recently published give, among other things, some very curious information on the population of France. The wealth which France has recently been discovered to possess has taken many persons by surprise. There must have been a vast amount of wealth accumulated by Frenchmen of all ranks to enable them to collect in two or three years so many millions for investment in their new Rentes, and that the vast proportion of these new Rentes is held in France is made evident by the very small amount of coupons for which France has now to make provision in foreign countries. When the issue was first made by M. Thiers, it was, largely by foreigners, and particularly by Englishmen and Germans, that the loan was taken. But gradually the French have bought their new stocks, and now the proportion of the French debt which is held out of France is very inconsiderable.

The consequence of this vast accumulation of wealth in France is that the comfort of the peasantry of that nation is now greatly increased, and the chances of long life wonderfully augmented. It would seem, as pointed out by Dr. Letheby in his now classical essay on the health of towns, that the French death-rate is somewhat lower than that shown by our registers, and that, too, in the face of the fact that the French estimate includes the deaths of still-born infants, which in England is passed by unnoticed.

"What is interesting to notice," says the *Saturday Review*, in a paper published on the 21st of November, 1874, "is that the wealth and the accumulation of wealth which these facts indicate are the acquisition of a population which, if not stationary, increases very slowly indeed. M. Block is proud of this, and sees in it a proof of the enlightenment and good sense of the nation to which he belongs. Political economists for a long time taught the doctrine that the road to prosperity was to keep the population within the limits of a comfortable subsistence. M. Block says that what Malthus preached the French have practised. But he says that the process is not due to a sudden and violent conquest of human nature, but simply to the gradual perception of what is fitting and necessary, which goes with increasing civilisation and intelligence."

Over-population is, according to this view, only possible when the people are degraded, ignorant, and without hope and ambition. Civilised people will be guided in this matter by the most obvious attention to what their own interests demand. In England a different mode of looking at things prevails. The population of England has doubled within a period in which the population of France has remained almost stationary, and with this rapidly increasing population we associate many things which we prize highly—our very great wealth, our colonial empire, our habits of independence, our love marriages, our trust that the crumbs will be provided for the sparrows.

But it must be remembered, too, that we have many evils to counterbalance the advantages we have gained by our colonies. The growth of a set of enormous and unwieldy cities over the length and breadth of England and Scotland is no unmixed boon to these countries. In cities it is that the healthy offspring of our rural population is reduced so often to the condition of the pallid and unfortunate factory hand, unfit to enjoy life himself, or to engender offspring strong enough to cope with the rigours of our northern climate. Among the victims to King Frost are tens of thousands of rickety children in the courts and alleys of our large industrial hives—children which ought never to have been born. Examples of such unfortunate populations are indeed rife enough in French industrial cities, such as Lyons, Lille, or Paris; but in France perhaps five-sixths of the nation live in the country, whereas in England about one-half of us live in cities.

We cannot, then, look forward without some misgivings to the sanitary condition of England and Scotland so long as our means of purchasing wheat and cattle are so exclusively those industries which require the artisan to sacrifice his health to a certain degree by sedentary occupation in towns. Doubtless, science is too far advanced at present to allow of the matter remaining undiscussed and without an attempt at a remedy; but there is, indeed, much to be done, and it is melancholy that a little cold weather or a slight impediment in trade should still produce such a rapid increase in the death-rate as we have alluded to.

## Notes on Current Topics.

### Medical Practice in 1700.

THE *Chemist and Druggist* quotes from the *History of Advertising* the following curious advertisement of a regular London physician found in the *Flying Post* of Jan. 6, 1700. It presents an idea of the medical practice of that date perhaps but little understood.

AT the Angel and Crown, in Basing Lane, near Bow Lane, liveth J. Peehey, a Graduate in the University of Oxford, and of many years' standing in the College of Physicians in London: where all sick people that come to him, may have for Six pence a faithful account of their diseases, and plain directions for diet and other things they can prepare themselves. And such as have occasion for Medicines may have them of him at any reasonable rates, without paying anything for advice. And he will visit any sick person in London or the Liberties thereof in the day time for two shillings and Six pence, and anywhere else within the Bills of Mortality for Five shillings. And if he be called in by any person as he passes by in any of these places, he will require but one shilling for his advice.

### Popliteal Aneurism.

At a meeting of the Clinical Society, on December 11th, Mr. Rouse mentioned a case of popliteal aneurism occurring in a man, aged 40, who had contracted syphilis twenty years ago, and whose mother had died of cancer. Two years before admission a small swelling appeared in right ham, which gradually increased, the leg becoming stiff and painful. Pulsation was noticed in the tumour six months before admission. A purring bruit could be heard. The

femoral artery was tied, and in a few days the tumour decreased in size, and pulsation ceased. It again enlarged, and a patch of skin over the tumour sloughed, and gangrene of the foot ensued, necessitating amputation of the thigh. The patient recovered well. Such cases are very obscure, in having sometimes given rise to great mistakes in diagnosis. In some cases malignant tumours have been considered aneurismal, and the reverse. On examining the limb after its amputation, there was found to be a large aneurism of the popliteal artery, the outer and inner walls of which had sloughed away so that a cavity had been formed filled with clot partly disintegrated, the popliteal trunk entering the sac above and the tibial arteries leaving it below. The popliteal vein was plugged by adherent clot.

### Aneurism of the Abdominal Aorta and Heart.

At a meeting of the Pathological Society of London, on the 15th inst., Dr. Dickenson showed a specimen of aneurism of the abdominal aorta, where the diagnosis had been very obscure. It was from the body of a man aged 78. In June, 1874, patient commenced to have redness and swelling of left testicle, followed by pains in course of left ureter, succeeded by obstinate constipation and vomiting. Bed-sores supervened, the abdomen was flaccid, and deep pressure on the left side of umbilicus caused great pain, but no swelling was felt. Soon after this, deep-seated pulsation was felt where the pain was felt on pressure, and this gradually became more distinct, until sixteen months after the first attack, when he had pain and syncope, with bloody stools, which carried him off. An aneurismal tumour was found pressing from the left side of the aorta and pressing on the left ureter, about an inch below the kidney, the ureter being stretched over it, and also pressing on the descending colon, into which it had burst.

Dr. Reginald Southey showed a specimen of aneurism of the heart, from a soldier who had served in India. A double murmur was audible over the lower part of the cardiac area and near the apex. Anasarca followed and left pleurisy, which was tapped, and four and a half pints removed by paracentesis. An aneurismal sac was found in the wall of the heart opening by an orifice the size of a quill into the left ventricle, near the apex.

### Dr. Edmunds' Post.

THE important posts of Medical Officer of Health and Public Analyst to St. James's—vacated by the death of the late Dr. Lankester—were filled on Monday last by the election of Dr. James Edmunds, of Savile Row. There were sixteen candidates for the offices, many of them men of well-known professional eminence, and nearly every member of St. James's vestry was present at the election. Dr. Edmunds was one of the most distinguished prizemen at his college, and among other classes, distinguished himself in that of chemistry under Dr. Letheby. He was one of the medical visitors sent down by the General Board of Health to Newcastle and Dundee in the year 1853 for the terrible epidemic of cholera which then visited those towns. He is a Member of the Royal College of Physicians of London, and has long taken an active interest in social and sanitary ques-

tions. He was also Medical Officer for some years to the H Division of the Metropolitan Police.

Dr. Edmunds is an able speaker and writer, and has shown immense energy, assisting on some of the forlorn hopes, such as the education of women in midwifery, and the up-hill war against alcoholic intemperance, a vice which causes so much disease and misery in England. He ought to be the most useful medical officer of health in London, and we hope to find him the most popular.

### Death from Chloroform.

THE *Canada Medical Record*, November, 1874, says: "One of these deplorable accidents occurred lately in Kingstown, the victim being a lady who was having a tooth extracted. The occurrence of like fatal issues is from time to time recorded in the news of the day, and most generally from chloroform having been taken during the performance of some minor operation, especially in dental surgery. We have been struck by the fact, and can only account for it by the nature of the operation, which generally permits or requires patients to assume a sitting posture. This position favours cerebral anæmia, which is the cause of death, so that the first remedy to be tried is change of posture as recommended by Nélaton—the patient to be inverted, with the feet upwards and the head downwards. In a case reported by Dr. Sims, of New York, life was restored by this method after respiration had ceased for fifteen minutes; and other cases are recorded where this plan had succeeded after other plans had failed."

When we read the account of this chloroform accident, which occurs nearly at the same time as the two deaths in London, one at the Eye Hospital in Moorfields, the other at the Royal Free Hospital, we may well ask why ether is not employed instead of chloroform. At the Royal London Ophthalmic Hospital both Mr. Critchett and Mr. Couper are in favour of ether *versus* chloroform. We really maintain that it is high time to ask why poor people's lives are to be sacrificed to routine.

SIR WILLIAM BOYD, one of the oldest graduates in arts and medicine of the University of Edinburgh, died last week. He was born in 1803, and was knighted in 1833.

A REMARKABLE success appears to have been attained by a little work entitled "The Pharmacopœial Companion to the Visiting List," by Dr. Bartley, the first edition of which has run out in ten days, and a second is already announced. The *brochure* under notice is a small oblong, of twelve pages, for carrying in the Pocket-book or Visiting List, and the idea formed by the author of giving to the busy practitioner a handy and reliable posological table of the medicines of the British Pharmacopœia arranged according to their action is excellently carried out, and deserves the success which it has so quickly obtained.

THE epidemic of diphtheria at the soldiers' huts on Woolwich Common has not disappeared, notwithstanding the sanitary precautions which have been taken. Within

the last few days three more children and one woman have been removed from the huts to the Herbert Hospital, in consequence of being attacked by the disease, but all the cases which now occur are said to be of a milder type than formerly, and there have been no more deaths.

In his return for the past quarter the Registrar-General for Ireland reports that there were registered in the 791 registrars' districts 33,768 births—a number equal to a rate of 25.4 in every 1,000 of the estimated population—and 19,636 deaths, representing an annual mortality of 14.8 per 1,000.

In England, during the same quarter, the birth-rate represented was 35.2 in every 1,000 of the estimated population, and the mortality 20.8 per 1,000.

The rates represented by the births and deaths registered in Ireland are higher than the averages for the corresponding quarter of the preceding five years. In the case of deaths the increase is considerable, and was mainly caused by the prevalence and fatality of those zymotic diseases which, if not altogether preventable, can be very much mitigated in severity by proper sanitary arrangements. Scarlet fever, which had been very fatal in the previous nine months, proved more destructive during last quarter. The disease was principally confined to the provinces of Leinster and Ulster, having still further declined in Munster. The returns for Connaught show an increasing fatality in that province, which had been comparatively free from this pestilence.

The following counties had the highest birth-rates:—Mayo 30.3 per 1,000 of the estimated population, Antrim 29.1 per 1,000, Kerry 28.4, Carlow 28.2, Dublin 27.2 per 1,000, Louth 26.6, and Armagh 26.0. The counties having the lowest birth-rates were—Meath 19.6 per 1,000, Fermanagh 21.4, Tyrone 22.1, Monaghan 22.5, Queen's 22.7, and Wexford 22.8.

## Foreign Medical Literature.

### PSORIASIS OF THE TONGUE AND BUCCAL MUCOUS MEMBRANE.

DR. MAURIAC, Physician to the Hôpital du Midi, of Paris, has written an interesting pamphlet on the above subject, from which we translate the following conclusions:—

Psoriasis of the tongue and of the buccal mucous membrane is a chronic inflammation in which two principal anatomico-pathological elements are constantly noticed. The first is a sclerous inflammation of the papillæ and superficial layers of the derma; the second, an epithelial hypersecretism which condenses in the form of grey, opaline, white plates, and which comes away in scales, squames, exclusively formed of epithelial cells.

Some authors have wrongly called this affection ichthyosis of the mouth, for it is evolved, whereas it is the property of ichthyosis not to be evolved, and to constitute a deformity rather than a disease.

There exist other anatomico-pathological elements beyond the psoriasis itself, but they are only of secondary importance. These are: lichen, pityriasis, ulcers, fissures, varicosity of the veins, glandular hypertrophy, &c.

In bucco-lingual psoriasis the parts attacked are in the order of frequency and gravity: the upper aspect and borders of the tongue, commissures of the lips, the

internal aspect of the cheeks, the internal aspect of the lips and their edges, the gums and palatine arch.

There are several phases in the anatomico-pathological process of bucco-lingual psoriasis: 1, the erythematous period; 2, sclero-squamous period; 3, formation of ulcerations, crevasses, and rhagades; 4, irregularity of the edges of the tongue, mammillar condition, with islands, furrows, &c., either resulting from a scar or from an atrophy of the derma, produced by the pressure of the scales.

The plates, bands, streaks, and scales formed by hypertrophy have a grey, pearly, opaline, nitrate of silver colour. This last colour is observed in the group of bucco-lingual psoriasis of arthritic or dartrous character.

In syphilitic psoriasis, the element of psoriasis, properly so-called, occupies the second rank in this kind of lesion. The principal anatomico-pathological elements are erosions, plates, with mucous membranes of variegated colours, ecchymotic, vegetating, or horny, &c., and deep syphilitic ulcers, with tubercles and gummata. Eruptions of diphtheritic character are more common in syphilitic psoriasis than in the other varieties.

The hypertrophy of the papillae may go on to the formation of papillomata. Such lesions are benign or malignant. It is by the transformation of such benign papillomata into malignant ones that bucco-lingual psoriasis becomes changed into epithelioma or canceroid.

There exists, says Dr. Mauriac, a kind of artificial, or provoked psoriasis, which is produced by external exciting causes, and is not the manifestation of any constitutional disease. This has been described by the name of smoker's plates. When this is kept up, whilst smoking is left off, we must admit behind it a predisposition either general or local, or a constitutional disease.

Arthritis and eczematous diathesis produce the bucco-lingual psoriasis of typical form, that in which there predominates during the whole time of the process sclerous dermatitis of superficial nature, and excess of epithelium. Arthritic bucco-lingual psoriasis and this kind just named form two kinds so near each other that it is impossible to distinguish them if there exist not on other points of the body lesions proper to arthritis or eczema.

In syphilitic psoriasis the specific element (mucous plates, tubercles, gummata, deep ulcers, &c. predominates, and the throat is usually attacked, which is not the case in the just-mentioned groups; but not all the cases of psoriasis which arise in the course of syphilis are syphilitic. Syphilis may be merely an exciting cause, and may provoke the formation of an arthritic or an epitheliomatous psoriasis.

When a psoriasis has remained a long time without being modified, and remains confined in its special anatomico-pathological characters, when it does not attack the throat, and resists a specific treatment of syphilis, the great probability is that it is not syphilitic, even if it occur in a patient evidently syphilitic.

There are cases of bucco-lingual psoriasis which are transformed into epithelioma, and constitute a distinct species from their commencement to their termination, that is, a species in which we discover no constitutional disease. But there are also cases of arthritic nature, or even artificially caused cases, which end in being transformed into epithelioma.

The functional disturbances are much more grave in this species than in the others, at least, in the advanced period of the disease. Among these disturbances, we may note salivation, lancinating pains which radiate to the ears, difficulty of speech and mastication, and enlargement of the glands, &c.

The transformation of bucco-lingual psoriasis into a malignant disease of the tongue, or epithelioma, which is almost the only cancer of the tongue, is one of the most important points in the history of the disease.

There are internal remedies which are specially indicated in the three kinds of psoriasis, in arthritis, in eczema, and in syphilis. Alkalies, and, in particular, the

bicarbonate of soda, are given in arthritic cases; arsenic in dartrous cases, and mercury and iodide of potassium in syphilitic psoriasis.

Mercury and iodide of potassium, which are administered as touchstones in psoriasis of doubtful nature, are very dangerous when there is no syphilitic element. They hasten the epitheliomatous transformations in certain cases of psoriasis, and aggravate their malignancy.

There is no special local agent to be employed in treating the different kinds of bucco-lingual psoriasis. Prudence and moderation are necessary in the using of substitutive agents.

## THE IRISH MEDICAL ASSOCIATION.

AN announcement which is contained in our advertising columns of to-day claims the very earnest consideration, and, we hope, the active co-operation of the profession, and especially of the Poor-law medical officers in Ireland. The Irish Medical Association, which has served our brethren through so long a period, and to which we do not hesitate to add, most of the benefits which have been secured to Irish Poor-law medical men is due, needs reconstruction on a wider and more useful basis, in order that it may pursue its work with greater efficiency. It has, under many difficulties, contested the Public Health arrangements in the interest of the public and of the profession, but in dealing with this, as with other equally important matters, the numerical strength and the administrative power of the Association has been insufficient. The time has come for a thorough and perfect reorganisation, for the breathing of new life, for the reinvigoration of the energy of the Association, and, if possible, for the reattachment to it of any other organisation which is labouring in the same field. We express a most earnest trust that a successful, permanent, and hearty reconstruction of the Association will be effected. The insignificant outstanding debts of all the coalescing organisations may be settled by a very inconsiderable effort of liberality, and, if jealousies be set aside and personal interests forgotten, we believe that an Association may arise which can exercise fivefold the influence of any that has hitherto existed.

A VACANCY in the surgical staff of the City of Dublin Hospital has taken place by the resignation of Mr. Tufnell who has been so long connected with the institution, and who will, we presume, now take the place of the late Dr. Hargrave as Consultant. We are aware that since the last election of a member of the Staff, the method of selection has been materially altered, and the appointment of a Surgeon in the room of Mr. Tufnell will not rest solely with the medical officers as heretofore it would have done.

AT a meeting of the Council of the Royal College of Surgeons in Ireland, held on the 17th inst., the following resolution was passed, viz.:—

That Registered Pupils of the College be permitted to read in the Library each day it is open, from 11 to 6 o'clock, and to study in the Museum each day it is open, from 11 to 3 o'clock, and that they also be admitted to the Preliminary Examination of the College without payment of any further fee than that which they have paid for Registration.

A MEETING of the Surgical Society of Ireland will be held on Friday evening, the 8th of January, when the following communications are set down for reading:—

Mr. H. Gray Croly, "On the Removal of a Hair-pin from the Female Bladder."

Mr. Barton, "On Excision of the Hip."

Mr. Swanzy, "On a Case of Amaurosis."

## Correspondence.

### KING AND QUEEN'S COLLEGE OF PHYSICIANS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Although it is not customary among gentlemen to notice anonymous letters in the public press, yet there are occasions on which it becomes a duty to do so. Such an occasion, we believe, is offered by the letter signed "A Fellow of the College of Physicians," published in the MEDICAL PRESS of the 23rd December.

The writer of that letter is ignorant, if not disingenuous, for he proposes to "restore" to the King and Queen's College of Physicians the right to elect by ballot, apparently in ignorance of the principle that a right cannot be "restored" to a corporation which it never possessed.

Your anonymous correspondent has dug up from the Minutes of the College a Report bearing date 31st December, 1867, just seven years ago, recommending the College to obtain the power to institute the order of Member, and he states that "nothing has since occurred to alter the case."

Your correspondent appears to be entirely ignorant of the fact that the proposal at that time to create the order of Member was a change of front rendered necessary by the action of the British Medical Association in favour of the "one portal" system, which threatened the existence of the licences of all the corporations; and he appears also ignorant of the fact that this blow was parried by the insertion into the Government Bill—7th July, 1870—of the following:—

"Clause 20.—After the passing of this Act it shall be lawful for the King and Queen's College of Physicians in Ireland and the Royal College of Surgeons in Ireland respectively to confer the title of Membership of such Colleges respectively on any person having higher qualification in Medicine or Surgery than is signified by the title of Licentiate, or other title in lieu of Licentiate granted by such Colleges respectively."

The Rev. Dr. Haughton accompanied the President (Dr. Banks) and Registrar (Dr. James Little) of the College to London, and assisted them in obtaining the insertion of the foregoing clause into the Government Bill.

It thus appears that your correspondent's statement that "nothing has since occurred to alter the case" is unfounded. The interests of the College were amply secured by this clause, which must be inserted in any future bill proposing the abolition of licences.

In conclusion, the same desire which influenced us in 1867 to protect the Licentiates, now urges us to oppose the creation of an order of Membership without ascertaining their wishes. To repeat the words of the Dissent, we say: "A question so deeply involving the interests of the Licentiates should not be dealt with behind their backs by a small body, and one in which they have no voice." Bearing in mind that this identical charge of inconsistency was brought forward by Dr. Churchill at the meeting at which the Dissent was read (December 2nd), and that it was fully answered by

the Rev. Dr. Haughton, we are reluctantly obliged to conclude that your anonymous correspondent is either ignorant of the subject of which he writes, or deficient in the candour we deem essential in so important a discussion.

We have the honour to remain, Sir,

Your obedient servants,

R. D. LYONS,

F. R. CRUISE,

S. HAUGHTON, CLK.

## Gleanings.

### Injuries from the Bites or Stings of Small Animals.

ONE morning (Dr. M. E. Weise, *Wiener Med. Presse*, 1874, No. 35), in the principal city of Albania, Dr. W. was summoned to see the prima donna of an Italian theatrical troupe which was performing there, and found upon his arrival that she was suffering from some affection of the finger, which increased in severity with such rapidity that she was unable to go on the stage, and was obliged to keep to her bed. The first impression made by an examination of the finger was that it had been attacked by a paronychia, which had spontaneously opened; and this impression was strengthened by discovering, upon inquiring into the history of the case, that there had been a loss of sleep during the previous three nights from the intense pain, which had been at first dull, and, later, throbbing in character. An improvement took place under the use of warm water dressings, to which the treatment had been limited, since the patient persistently refused to allow an incision to be made; and further examination showed that a similar state of affairs existed upon the other hand. It was then stated by the doctor it was probable that these affections were caused by the bites or stings of some poisonous animal, and this was confirmed by the entrance of two other members of the troupe, complaining of similar painful swellings in their fingers. It was then found that the members of the troupe had killed many European scorpions and hornets in the foul and badly-kept room upon the floor of which they all slept. On the next day, the "page" of the company, who was the child of the director, was found to be suffering in a similar way. The agreement as to the locality at which the suppuration took place in these different cases was very striking. It was always in the furrow between two of the phalangeal articulations, and upon the volar side of the joint in six of the cases; being upon the dorsal aspect in but one.

In all four of the persons who were the subjects of this accident, the thumb was the part of the hand which was either first or exclusively affected. The trouble lasted about one week, and during the first three or four days the patients suffered severely from pain and loss of sleep. If the affection was left to itself it broke upon the fourth day, and then, according to its size or depth, resembled either a panaritium in the strict sense of the word, or a simple pustule, of the size of a pea, or perhaps as large as a hazel-nut. This was followed by a sense of relief, and there was soon a real improvement in the state of the patient, manifested by a return of sleep and appetite. The discharge of pus continued of considerable amount, and led to the formation of a loss of substance of circular form, which was but slowly replaced, and left a scar which was visible for a long time. As healing progressed, the epidermis fell off or was removed with the scissors; the newly-formed skin scaled off for some time, and the indurated edge of the cicatrix which was being formed caused much annoyance by the itching which was present in it. At the commencement of this affection it is almost always possible by careful examination to discover a black point, of the size of the point of a needle, situated near the centre of the tumefaction.

In the recent cases in Scutari, Dr. W. thinks that the choice as to their origin lies between the *Scorpio Europæus*, which is very frequently met with in Turkey, and the hornet (*Vespa crabro*), which is more rarely seen. It is well to be acquainted with the important constitutional symptoms to which lesions of this character give rise, so as not to be deceived by them when their origin is not plainly indicated.

## NOTICES TO CORRESPONDENTS.

**82** CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Dr. THOMAS WILKINSON, Manchester.—We shall be glad to hear some hints as to the therapeutical and food value of alcohol. There are such various opinions on this point, from the teetotallers, who assert that alcohol is not a food in any way, and merely a drug like chloroform, to the disciples of Todd, that much discussion is required to ascertain what the real interpretation of experience ought to be concerning alcoholic drinks. As to tobacco, it has nothing to be said in its favour, we suppose, by medical practitioners, whatever outsiders and literary men may do. It is clearly a cause, a very frequent cause, of diseases of various kinds, and no doctor, of course, should encourage the use of tobacco either by precept or example.

CHARLES BRENT, Liverpool.—The controversy about the Contagious Diseases Acts goes on as usual, and we hear of a paper likely to be read by Mr. Acton at the Royal Medical and Chirurgical Society on similar Acts in France and Belgium. The opposition to the Acts is powerful, and the party against them is well supplied with the sinews of war and with enthusiasm, neither of which are present among the upholders of the Acts to any great extent at present. Such being the case, it is possible that the Acts may be abandoned for a time. They will probably be supplied by voluntary hospitals, which have long been much needed for venereal diseases.

Dr. THOMAS STAFFORD, Leeds.—There is an article on *Mébranous Dysmenorrhoea* in the "Archives Générales de Médecine" of 1873-4, which is very full. The author asserts that patients who suffer from the disease are sterile.

GRAINS OF HEALTH.—These three words have been blazoned before the public during the past few months in every conceivable mode and position. It now turns out to be the title of another patent medicine in the shape of a film-coated pill, which, doubtless, like "Du Barry's Revelant," *Arabea Food* (lentil flour in plain English), will enable the public to have "no more doctors' bills or any other medicine."

Dr. M. T. S. should write to Mr. Trimmer, Secretary to the College.

GOOD ADVICE TO A DYSPETIC.—A gentleman saw an advertisement that a receipt for the cure of dyspepsia might be had by sending two postage stamps to the advertiser, and the answer was, "Dig in your garden and let whisky alone."—*Boston Journal of Chemistry*.

LEPROSY.—In Casell's "Bible Educator" for January, writing on the leprosy of Scripture, Dr. Greenhill is of opinion that the disease was "multiform and changeable," modified by various complications, and comprising several species more or less distinct; that some of these varieties were contagious, and others non-contagious, and that all the contagious species rendered the patients ceremonially unclean; that is, was not a special or miraculous disease, existing only in those times and countries, but an ordinary malady, used occasionally by God for miraculous purposes; that it was not incurable by human means, though troublesome and obstinate; that it was not hereditary, though a disease of common occurrence among the Jews; that it was not the same as elephantiasis, though it is possible that this disease may occasionally have been complicated with it; that there is no evidence that any case of elephantiasis is mentioned under the name of leprosy, in any part of Holy Scripture; and that if the disease known as elephantiasis occurs at all in the Bible, it is probably in the case of Job.

Dr. C. H. F. R.—We will endeavour to find space for the whole in the form suggested.

Dr. COLLINS McELROY, Zanesville, is thanked for his complimentary note.

Dr. C. C.—Your suggestions shall receive attention.

SEVERAL commonfections are unavoidably postponed on account of the space occupied by Index.

ARMY MEDICAL SERVICE.—The next examination of candidates for commissions in the Medical Department of the Army will be held in London on the 15th and 16th of February. Applicants for admission must address the Director-General at once.

W. F. O' L.—We have no means of advising you as to the stability of any insurance company, and should, therefore, not wish to express an opinion thereon. The Government Statistical Report on the subject will afford you every information, but it will be difficult for you to take from it a just judgment on the subject, and impossible for us to give space to the examination of it.

NAVY MEDICAL SERVICE.—The next examination of candidates will take place at the London University on Feb. 15th. Dr. Armstrong will supply the necessary forms to candidates on application to the Admiralty Medical Department.

THE "COSPATRICK."—This fine vessel, of which report is current as we are going to press that she has been burnt in mid-ocean with nearly 600 souls on board, only three of whom were saved, was in medical charge of Dr. J. J. Cadle, an officer who is spoken of with great respect by all who knew him, and whose loss will be much deplored. The deceased was, we believe, a graduate of the Edinburgh University, and has been several voyages in charge of the same company's vessels.

LUCIDITY OF DEFINITION.—The *Philadelphia Reporter* notices a book by Benjamin Paul Blood entitled "The Anæsthetic Revelation and the Gist of Philosophy." What this work refers to will be clear from the following extract:—"By the Anæsthetic Revelation I mean a certain survived condition, or uncondition, in which is the satisfaction of philosophy by an appreciation of the genius of being, which appreciation cannot be brought out of that condition into the normal sanity of sense!"

## VACANCIES.

Royal College of Surgeons of Ireland. Professorship of Midwifery. (See Advt.)

Newcastle-on-Tyne Lunatic Asylum. Assistant Medical Officer. Salary, £100 per annum, with board and apartments. Forms of application to be obtained from the Superintendent.

Essex Lunatic Asylum. Second Assistant Medical Officer. Salary, £100, with board. Applications to Dr. Campbell, at the Asylum, Brentwood.

University of Edinburgh. Examiner in Medicine. Full particulars of the Secretary.

Great Northern Hospital, Caledonian Road, N. Physician. Honorary Surgeon. Honorary. Applications to be addressed to the Secretary.

Parish of St. Pancras, London. Medical Officer of District No. 8. Salary, £130 per annum. Applications, accompanied by testimonials, to be addressed to the Vestry Clerk, at the Vestry Hall.

Middlesex Hospital. Surgical Registrar. Particulars may be obtained of Mr. Evans, at the Hospital.

Hospital for Women, Soho Square, London. Surgeon and an Assistant Physician. Honorary. Applicants must address the Secretary.

Greenwich Union. Medical Officer to the Workhouse. Salary, £200. Candidates will be required to devote their whole time to the duties. Applications to the Clerk of the Guardians.

Worcester Union. Medical Officer for District No. 2. Full particulars of Mr. Knott, Worcester.

## APPOINTMENTS.

ARMSTRONG, G. C., M.D., Superintendent Medical Officer of Health for the Blackrock, co. Dublin, Urban Sanitary District.

BEDFORD, C. F., M.B.C.S.E., Medical Officer for the Workhouse, and Medical Officer and Public Vaccinator for the Slaford District of the Slaford Union, Lincolnshire.

BROWN, R., M.D., Sanitary Officer for the Rathmines and Rathgar Urban Sanitary District.

CARR, G. E., M.B., L.R.C.S.I., Resident Medical Superintendent of the Castlebar District Lunatic Asylum.

FAUBERT, W., M.B., Superintendent Medical Officer of Health for the Clontarf Urban Sanitary District.

GAMBLE, B., L.K.Q.C.P.I., Sanitary Officer for the Enniskillen Urban Sanitary District.

HERAPATH, C. K. C., L.K.Q.C.P.I., Medical Officer to the Bristol Dispensary.

IRVING, J., M.B., C.M., House Surgeon to the Huddersfield Infirmary.

KELLY, M. J., M.R.C.S.E., L.K.Q.C.P.I., Medical Officer, &c., for the Castledermot Dispensary District of the Athy Union, co. Kildare.

KENNEDY, E., M.R.C.S., Surgeon to the Ardwick Dispensary, Manchester.

KEMMIS, H. M., L.K.Q.C.P.I., M.R.C.S.E., Medical Officer and Public Vaccinator for No. 2 District of the Bridgwater Union.

LAWRENCE, J., M.D., C.M., M.R.C.S.E., L.M., Medical Officer to the new Infirmary, Darlington.

M'CARTHY, E., M.D., M.R.C.S.E., Medical Officer and Public Vaccinator for No. 3. District of the Buckingham Union.

O'DEA, P. St. L., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer, &c., for the Spiddal Dispensary District of the Galway Union, and Medical Officer to the Royal Irish Constabulary, Spiddal and Inverin Stations.

POLLOCK, J. F., M.B., Sanitary Officer for the Blackrock, co. Dublin, Urban Sanitary District.

POWELL, J., M.R.C.S.E., Senior House Surgeon to the Royal Free Hospital.

THOMPSON, H., M.R.C.S.E., Medical Officer and Public Vaccinator for No. 2 District of the Sevenoaks Union.

WALSH, R. P., L.K.Q.C.P.I., Superintendent Medical Officer of Health for the Enniskillen Urban Sanitary District.

WARD, M. A., M.B., Superintendent Medical Officer of Health for the Rathmines and Rathgar Urban Sanitary District.

## Marriages.

BLAIRIE—DUNBAR.—On the 23rd inst., at Trinity Presbyterian Church, Notting Hill, James Blairie, M.A., to Georgina Jane, younger daughter of Surgeon-General J. A. Dunbar, M.D., late Bengal Army.

NEWBERRY—SPICER.—On the 22nd inst., at St. Nicholas, Leeds, Kent, W. J. Newberry, M.R.C.S.E., of Beresford House, Sutton-Valence, to Annie P. Spicer, of Burgess Hall, Leeds.

## Deaths.

COLE.—On the 14th Dec., R. J. Cole, M.D., Surgeon (half-pay), late of the 20th and 1st West India Regiments, of Great Brunswick Street, Dublin.

MILLAR.—On the 10th Dec., at York Terrace, Leamington, James Millar, L.F.P. & S. Glas., late of the Peninsular and Oriental Co.'s Service.

NICHOLSON.—On the 12th Dec., John Nicholson, M.D., New Brighton, Cheshire, aged 72.

THURSFIELD.—On the 14th Dec., at High Street, Bridgnorth, the dearly beloved wife of William Thurstfield, M.D., aged 86.

**IMPEDIMENTS of SPEECH.**—The Rev. ALEX. J. D. DORSEY, B.D. Cambridge, Lecturer on Public Reading and Speaking, K.C.L., receives resident and visiting Pupils suffering from Weak Voice, Indistinct Articulation, Stammering, and other defects. References.—Sir William Fergusson, Bart., Prof. Humphry, Henry Bullock, Esq., Dr. Morell-Mackenzie, Dr. Sutherland, John Croft, Esq. 13 Prince's Square, Baywater, W.

**HOSPITAL SUNDAY, 1875.**—NOTICE IS HEREBY GIVEN, that a PUBLIC MEETING will be held on MONDAY, the 4th day of January, 1875, at Half-past Two o'clock, in the Egyptian Hall of the Mansion House, for the purpose of settling the preliminary arrangements for Hospital Sunday, 1875, and of electing the Council, &c., for that year.

All ministers of religion in the metropolis and its neighbourhood, the authorities of the various hospitals and dispensaries, and others interested in the movement, are invited to be present.—By order.

HENRY N. CUSTANCE, Secretary.

**ARMY MEDICAL DEPARTMENT.**

24TH DECEMBER, 1874.

**AN EXAMINATION of CANDIDATES for COMMISSIONS** in the Medical Department of Her Majesty's Army will be held in London on the 15th FEBRUARY, 1875, and following day.

Candidates having the necessary qualifications to practise Medicine and Surgery under the Medical Act, and who are unmarried, and not under 21, nor above 28 years of age, are eligible to attend. Applications for admission to the examination should be made in writing, without delay, to the Director-General of the Army Medical Department, War Office, London.

W. M. MUIR, Director-General.

**ADMIRALTY, MEDICAL DEPARTMENT OF THE NAVY.**  
9 New Street, Spring Gardens, S.W.,  
20th December, 1874.

**NOTICE OF EXAMINATION of CANDIDATES FOR THE NAVAL MEDICAL SERVICE.**—Notice is hereby given, that a Competitive Examination of Candidates for admission into the Medical Service of the Royal Navy, will take place at the University of London, Burlington Gardens, on Monday, 15th February, 1875, and following days, at 10 o'clock.

Candidates must present themselves at this Department, for Physical Examination, at 11 o'clock, on Thursday, 11th February, 1875, when, should they be found in all respects eligible, they will be permitted to appear for examination.

The necessary forms to be filled up by Candidates will be supplied on application to this Department.

A. ARMSTRONG,  
Director-General.

**IRISH MEDICAL ASSOCIATION.**

**A MEETING of the COUNCIL of the IRISH MEDICAL ASSOCIATION** having been summoned to take into consideration the present affairs of the Association, and to deliberate upon the propriety of electing an Hon. Sec. in room of Dr. Quinan, resigned, it was arranged that the appointment of an Hon. Sec. be postponed until the collective opinion of the Association on the present juncture be ascertained; as the Council finds that, unless a special collection be made to relieve the Association from its present difficulties, it will be impossible to conduct its affairs.

It was resolved—"That the President be requested to communicate with the Hon. Secretaries of the Branch Associations, calling upon them to use their best efforts in obtaining from the members of the Association, and the profession generally, aid in carrying out the object of the above resolution."

It was also resolved—"That the President be requested to summon a special meeting of the Association on an early day, to consider the expediency of reorganising the Association, and to raise a special fund for the liquidation of its outstanding debt."

In accordance with the foregoing resolutions I convene a special general meeting of the Irish Medical Association for Wednesday, the 6th January, 1875, at 12 o'clock, at the Royal College of Surgeons.

(Signed) HENRY J. SMITH,  
President Irish Medical Association.

**THE STEWART INSTITUTION FOR IMBECILES, AND LUNATIC ASYLUM, LUCAN.**

PATRON:—H.R.H. THE PRINCE OF WALES.

This Institution was founded in 1860, and has already attained a large measure of success. It is situated in a healthy locality, and is under the superintendence of a Resident Physician, with trained teachers, who endeavour by the most improved methods to develop the powers, mental and physical, of Imbeciles.

To the pupils who can receive such instruction useful trades are taught. In that of mat making, particularly, excellent progress has been made, and an inspection of the work is invited either at the Institution or at the office.

The Institution is the only one of its kind in Ireland, and is mainly supported by voluntary contributions.

Pupils are admitted free by election, or by payment of 25s per annum. A higher rate is payable for separate accommodation.

Contributions to the fund for the erection of the proposed extensive buildings at Palmerston are earnestly solicited.

Each donation of Five Guineas gives the donor a life-vote. Annual Subscribers are entitled to one vote for each half guinea paid.

An Asylum for Lunatic Patients of the middle classes, under a well-organised administration, also forms part of the establishment.

Full particulars as to the working of both Institutions, terms, &c. can be had at the office,

40 MOLESWORTH STREET, DUBLIN,  
W. O'NEILL, Secretary.

Established 1848.

**PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.**

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.,  
&c. (King's Coll.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable Investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle, that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

COMPETENT ASSISTANTS provided without expense to principals. No Gentlemen recommended whose antecedents have not been inquired into.

**PRACTICES AND PARTNERSHIPS NOW OPEN** for Negotiation (in addition to those advertised in Dr. Langley's List, which is sent post free on application).

Z 81 Within 15 miles of London, a JUNIOR PARTNERSHIP in a good GENERAL PRACTICE, in a suburban locality. A fourth share for disposal, with succession to further share hereafter upon equitable terms. The receipts are £1,350 a year, and there is great scope for increase. There is little dispensing. The Junior could at first reside at the branch surgery. Premium, £875, part of which may be left on security, and paid by instalments.

Z 78. First-class LONDON PRESCRIBING PRACTICE, held by the Incumbent for many years. A Partnership introduction would be given, but the connection could not be transferred to any gentleman not highly qualified nor unless he were accustomed to the best society. The income averages about £4,500 a year. Midwifery fees from 7 to 10 guineas. The residence is well situated near the most fashionable west-end squares.

Z 79. In a fashionable watering place, an OLD-ESTABLISHED FAMILY PRACTICE, the average receipts from which are between £1,000 and £1,200 a year. Midwifery having been lately declined, there is little obstetric practice, but there is scope for almost unlimited increase, if this department were resumed. The house is large, very convenient, and very near the shore; it contains twenty-three rooms, with detached groom's house, stabling, &c.; it can be purchased or rented. Ill-health and advanced age the cause of retirement. The premium would depend upon the introduction required, but no gentleman need negotiate unless he has at command at least £1,000.

Z 80. In a prosperous and picturesque district, an OLD-ESTABLISHED PRACTICE, yielding in actual receipts £1,100 a year. Age the cause of retirement. Appointments bring in £62 a year. The house is well situated, contains 10 rooms, with detached surgery, offices, stabling, and large garden. Rent 40 guineas. The working expenses amount in all to about £300 a year. An effective introduction by quasi partnership or otherwise as long as may be desired. Part of the premium may be paid by instalments. The whole connection is safely transferable to a suitable gentleman, and there is great scope for increase, as there is a population of about 15,000 inhabitants.

Z 77. PARTNERSHIP in a large and prosperous town within 100 miles of London. A gentleman conducting an increasing practice desires to secure the co-operation of a doubly-qualified partner. Receipts last year were upwards of £1,100, and the present year will show a considerable advance. As there is great scope for increase the Incumbent believes that the receipts could be doubled by efficient co-operation. The expenses of the Practice are moderate, as the patients reside within a short radius. Public appointments produce about £200 a year. The Half Share for transfer. Part of the premium might be left on security if the applicant were suitable.
